There are already medical services of different kinds in this country, and none of them has yet distinguished itself in promoting medical progress. One reason for this is that public authorities do not provide staff or facilities for much more than good modern practice in their hospitals, and feel unable to devote public money to research. On account of this it would be very unwise to make any more hospitals solely dependent on public money which is allocated by Parliament or a local authority. Another difficulty in a service is that the encouragement of new developments is in the hands of the few at the head of the service, so that their sympathies and interests give a bias to the service as a whole. For this reason a national hospital service is to be condemned, and initiative must be maintained in many centres.—I am, etc.,

London, W.1, Aug. 5.

Medical Service under the New Order

SIR,—It may not be considered too revolutionary to suggest that the Medical Planning Commission sees to it that the general practitioner has a fairer deal under the post-war new order than under the old.

Let us look at his lot under the old order. Too often he is a tired man. Notwithstanding partnerships and arrangements between neighbouring practitioners off-duty is hard to get. He copes with a confinement after a full day's work, and after conducting a confinement in the night he has to be merry and bright or work next day. Before his morning consultation hours, and often before his breakfast, he has urgent calls to people who have suffered rather than send for him in the night. Through people having suddenly become ill, or through their not having had anyone to send earlier in the day, he often has to work a good part of the afternoon. The "pop" after his evening consultation hours is so popular that it has often to be carried out a duplicate or triplicate. He never goes to bed feeling that his work is done. The doctor must work like this. The public demands service twenty-four hours out of twenty-four. The Ministry of Health, Insurance Committees, and various public bodies expect it to be given. Further, the doctor has to pay

towards a mortgage on his practice and very likely on his house. He has to pay for his sickness, for his holidays. He must save for his dependants. Provision for himself he need not make. The Registrar-General's returns show that his life is short. He usually works as long as he lives.

The post-war new order aims at giving the people economic security, healthy conditions, short hours, and big pay. What is sauce for the goose is sauce for the gander. Could the Medical Planning Commission make it an item on its agenda to see that the practitioner, serving a people basking in the sunshine of the new order, gets on himself just a touch of that same sun? The Commission need have no fear that any injustice will be done to the public. A doctor who is working within the bounds of possibility cannot fail to give efficient service. He might have to bear with some bureaucratic control, but there need be no bogey about this if his terms of service were also bureaucratic—that is, economic security, reasonable pay, holidays, off-duty, pensions, etc.

Industrially, it is established that the output of a tired man working overtime does not compare with that of the rested man, and that it pays to maintain the health of the workers. Doctors are just workers. The doing away with the drudgery of doctoring would be a capital thing for the nation and for the doctor.—I am, etc.,

Birmingham, Aug. 7.

J. RENWICK.

Wholemeal Bread

SIR,—In his letter (July 12, p. 64) Dr. R. A. Murray Scott compared wholemeal bread with national 85% bread, and criticized some of the statements made by the Medical Research Council in its second memorandum on bread. There are a number of inaccuracies in Dr. Murray Scott's communication.

In the first paragraph he says that the M.R.C. does not give grounds for the statement that "it is undesirable to increase the roughage in wartime diets," and also that he can only find one reference in the literature to work carried out on the effect of wholemeal bread. The M.R.C. clearly states that wartime diets already contain much vegetable food and derive a large amount of roughage from it. The following references may be added to the single one mentioned: Cramer, W., *Lancet*, 1923, 1, 1406; Gross, L., *J. Path. Bact.*, 1924, 27, 27; Evans, Geoffrey, *British Medical Journal*, 1929, 2, 1044; Mottram, J. C., *Practitioner*, 1930, 74, 691; Lang, E., Gravelle, L. A., and Nash, T. P., *Cereal Chem.*, 1935, 12, 356; Abelin and Biderbost, *Biochem. Z.*, 1932, 247, 429.

Dr. Scott says that until recent years wholemeal was the only meal available and was eaten in double the quantity. Now from personal knowledge I know that germ meals consisting of a mixture of white flour and germ, prepared in the manner suggested in Dr. Scott's concluding remarks, have been available to the public for over fifty years. The keeping properties of these meals are better than those of wholemeal, as the germ is sterilized before being mixed. The vitamin B potency is very little affected by this treatment. The keeping properties of wholemeal flour are mentioned by Dr. Murray Scott, who says that flour stored at temperatures below 60° F. was in sound condition at the end of six months. This is not a fair test, as it would not be practicable under ordinary manufacturing conditions to store flour at such temperatures in the summer.

No mention has been made of the disease in bread known as "rope," caused by a slime-forming bacillus (*Bacillus mesentericus panis viscosus*). The disease is liable to occur in bread, particularly in hot weather, if care is not taken in the baking process. Wholemeal bread is particularly susceptible, and would in my opinion be more liable to it than the 85% meal.

The addition of calcium salts to wheat flour is mentioned, and a table showing nutritive values of wholemeal, 85%, and white flour after addition of calcium is given. Here Dr. Scott is unfair to white bread, as the figure he gives for vitamin B₁ potency does not take into consideration the added synthetic aneurin. No calcium will be added to white flour without the addition of vitamin B. I am in agreement with the policy of adding calcium to flour, but experiments show that the choice of the carbonate is not a good one; better results are obtained if the calcium salt is a soluble one. The following references to experimental work support this statement: Mottram, J. C., and Palmer, N., *Cereal Chem.*, 1937, 14, 683; Palmer, N., and Mottram, J. C., *Biochem. J.*, 1939, 33, 512; Palmer, N., *Biochem. J.*, 1939, 33, 853.

In Canada and the U.S.A., Dr. Scott says, they are quite happy about additions to flour. So far as I know, National Food and Research Councils have published approved "enrichment" factors, but no Government action has been taken, with the result that tablets containing thiamine, nicotinic acid, riboflavin, iron, and vitamin C are on sale to bakers and millers alike with no restriction; so that it would seem possible to obtain bread that theoretically should be a "food of the gods." Whether such synthetic additions are equal to, or as safe as, natural products remains to be seen. For my part I think that the British Government would be wise in wartime to restrict additions of synthetic products as much as possible and to rely upon natural foodstuffs. Palatability is a factor which has not been discussed so far and was not mentioned in the M.R.C. memorandum. The baking process plays an important part in deciding whether the finished bread will appeal to the public; the suggested additions should not affect the production of good bread in any way, but unfortunately it has been my experience that brown breads, unless particular care is taken, are not always palatable, and therefore one prefers other bread, knowing full well that it is not so nutritious.

The 85% national loaf and germ breads are, in my opinion, more palatable than wholemeal, and also more attractive in their external and general appearance.—I am, etc.,

J. C. MOTTRAM.

Tuberculosis in Recruits

SIR.—The incidence noted by S. H. Graham and M. Davies (June 21, p. 920) of tuberculosis in recruits referred for the first time by the medical boards to the staff of the Welsh Memorial Association appears to me a very much lower figure than 6% if based on the total number of recruits examined by medical boards. The authors do not make any recommendation for grading quiescent or suspected cases. Tuberculosis officers can be of great help to the chairman of the board in these difficult cases and save the country pension claims if activity develops later.

The view of the authors against the advice of the Horder Committee that radiological examination of all recruits "was impracticable at the present time" has been answered in my communication on x-ray diagnosis of tuberculosis in the *Journal* of October 26, 1940 (p. 573). In fact, Welsh figures confirm my statement that in spite of increased x-ray examination new cases and contacts diagnosed as tuberculosis in England have fallen considerably from 51.2% in 1926 to 35.6% in 1938. The Committee of Inquiry into Anti-tuberculosis Services in Wales and Monmouthshire in 1937 found that for the previous year 20% of cases of tuberculosis proved fatal in three months and 47% of the patients died in less than twelve months. Also for every 100 deaths from tuberculosis 1,055 x-ray examinations were made as against only 467 in England; yet of the new pulmonary suspects only 24.02% were found to be tuberculous by the Welsh dispensaries. From the Ministry reports a diagnosis of tuberculosis was made in 30% of new cases and contacts examined in 1935 in Wales as against 45.6% in England.

G. Jessel states (*Brit. J. Radiol.*, March, 1941) that though more cases were x-rayed in England in 1938 than in 1930 the number of early cases—that is, T.B.— and T.B.+1—decreased in 1938, while the advanced cases—T.B.+2 and T.B.+3—have increased. His explanation that x-ray facilities were inadequate or slight in 1930 and that clinical diagnosis of T.B.— cases was unreliable is, to say the least, unconvincing.

The reports of the medical officers of health for Sheffield, which for a number of years in the past had the lowest tuberculosis death rate among the larger industrial cities, concentrate their preventive work on the T.B.— cases. Yet in 1935, of their sputum-positive cases 40% died within the year. Of the 4,271 sputum-positive cases treated from 1911 to 1922, only 5.9% were alive in 1930 in that city. If one analyses mass radiology figures, so often quoted, the percentages of cases of active tuberculosis are similar—namely, 0.5% (E. L. Cooper, *Journal*, August 24, 1940, p. 245) in 22,000 and 0.56% (D. Galbraith, *Journal*, May 10, 1941) in 100,000 Australian recruits. On the other hand, if the various types of x-ray shadows are included the percentage evidence of tuberculosis in these two observers' findings is 23 and 2.07 respectively—a marked difference. By mass radiology 8% of Storm Troopers in Germany are found to be tuberculous. S. C.

Shanks (*Brit. J. Radiol.*, February, 1941) estimates, from x-ray figures published abroad, early tuberculosis in 1% of apparently healthy recruits. Though based on small sections of the community he gives for England 0.6% to 5%, U.S.A. 1.8% to 3.9%, Germany 2%, Spain 4.5%, and China 17.9%. In short, the variation in diagnosis of tuberculosis by x-ray enthusiasts is as wide as that of the clinical advocate, only the latter still has to assess the grading of fitness.

In my October communication I stated my experience as No. 2 examiner of a medical board coming across one or two suspect chest cases in an average session. At the rate of two sessions a week in twelve months I must have examined a probable total of 2,500 recruits with an estimated 150 suspects in the few minutes available per individual—namely, 6% of total recruits, of whom a third, or 2%, may be considered to reveal tuberculosis by the average dispensary x-ray diagnosis. In my N.E. Divisional area with an urban and lesser semi-rural population the non-reserved age groups show a greater normal prevalence of tuberculosis. Many of my cases may not have been referred to the dispensaries and a lower grading may have been agreed by the chairman, who, more than once, concurred in the opinion that the x-ray examination did not help in some of these cases. The number of recruits referred with physical signs by medical boards in Wales—namely, 216—is small. This must be the case probably in many areas if board examiners have had no previous experience of chest cases.

Thus one may quote the case of a man aged 33 who was clinically diagnosed as tuberculous with, later, positive sputum; when he was referred to a tuberculosis centre the report was: "X-ray and clinical findings not marked." Later a medical board rejected him on the doctor's report. As a public administrator one is faced at the present time with defence service personnel discovered whilst on leave to be suffering from tuberculous pleurisy, etc., who are rejected subsequently as unfit with no established diagnosis of tuberculosis, in some of whom x-ray investigation later has not been helpful.

In conclusion I would again plead for a special category for quiescent and non-infective suspect cases not for total rejection and for at least one examiner in a board with some chest experience. Also the Ministry of Health should collaborate with the Ministry of Labour and the Defence Services in initiating research into the incidence of T.B. as shown by available statistics. Every suspect chest case must also have the benefit of periodical x-ray investigation.—I am, etc.,

Leeds, July 24.

Z. P. FERNANDEZ.

Activity of Tuberculosis

SIR.—In his paper on carriers of tuberculosis (May 3, p. 665) Dr. James Maxwell observes that the presence of tubercle bacilli in the sputum does not of itself indicate active tuberculosis of the respiratory tract. I gather from his letter in your issue of July 26 (p. 136) that Dr. Alec Wingfield accepts this conclusion. Whether we shall all follow his example depends, it seems to me, on our definition of the word "activity." This is not hair-splitting, for the question as to whether a lesion is active or not is most important to the patient, the physician, and the general public. May I call on my old friend and teacher, Dr. Maxwell, to supply this definition?

I should like to outline two types of case: (a) Symptoms are slight: breathlessness on exertion and a little sputum; physical signs are those of apical fibrosis; x-ray picture shows a tuberculous lesion in this situation and the sputum is positive; a period of observation shows that the lesion is not getting larger nor the patient more sick. (b) Classical symptoms and signs of pulmonary tuberculosis are present; x-ray picture shows a tuberculous lesion in the lung and the sputum is positive: the lesion is getting larger and the patient more sick. I suggest that both these patients have active disease; in (b) the process is advancing; in (a) it is not. Dr. Maxwell suggests that (a) has not got active disease but should be classed as a carrier. I cannot agree with this. It seems to me that when a patient has a demonstrable tuberculous lesion in the lung and when he has sputum which contains tubercle bacilli then the lesion is, by definition, active. As Dr. Maxwell says in his letter (July 12, p. 65), we do not apply the term "active" only to those lesions which are advancing. An active lesion may be advancing (as in (b)), or stationary (as in (a)), or retrogressing (as in the patient who is

improving under treatment); but if tubercle bacilli are found in the sputum it is still active. If they are not found the test is inconclusive, and one must decide the question of activity on other evidence. Is this the view of most tuberculosis physicians? Please let us have a generally accepted definition of activity before the word has lost all meaning!—I am, etc.,

Westminster, S.W.1, July 28.

LAWRENCE ROBERTS.

Carriers of Tuberculosis

SIR,—Dr. E. Fraenkel in his letter (June 21, p. 946) does not like the term "tuberculosis carrier" as advocated by Dr. James Maxwell in his paper (May 3, p. 665). To my mind the term is admirable. It may not be correct pathologically, but from a public health standpoint it has tremendous propaganda value, and the detection of tuberculosis could do with some propaganda.

I would go further than Dr. Maxwell and include in his unsuspected carriers all those undiagnosed adult men and women who have very chronic cavities in their lungs and daily expectorate tubercle bacilli in their homes and factories. These people—apart from a productive cough which they call "bronchitis" or "catarrh" or a "smoker's cough"—seldom complain of anything else and rarely seek medical advice. After many years, and if the disease progresses, other symptoms appear and they are eventually diagnosed, or maybe haemoptysis brings the disease to light. But in the meantime these people have infected one or more members of their families, and perhaps other home or work associates.

Tell the public that a person can "carry" tuberculosis without feeling ill, and that he can infect and kill others (with poor resistance) and go on living himself. The fear of what an x-ray examination will show prevents many people from being x-rayed. I think they would readily submit to x-ray examination which might show them to be "carriers" (with the possibility of future breakdown) and not a "real" consumptive, like So-and-so, who has died of the disease. Having prepared the ground thus, the examination of contacts of young persons with tuberculosis (of probable human origin) must not rest with x-ray examination of other young persons in the home. Parents and other adult members of the family must be x-rayed, and, where there is a productive cough, sputum be investigated. If the results are negative, then the carrier should be sought at school, workshop, office, church, etc. The carrier does not necessarily require institutional treatment, especially in these days of limited accommodation. Tuition on the prevention of infecting others can be taught at the dispensary. Work can be continued if the only symptoms are cough and sputum, and the evening temperature and B.S.R. are normal. Serial x-ray films will decide when and if other treatment is necessary.

Spot the carrier of tuberculosis now and do not wait for bigger schemes of mass radiography to do it.—I am, etc.,

The Liverpool Sanatorium, Frodsham, Aug. 4.

R. WRIGHT.

Classification of Cases of Albuminuria

SIR,—Dr. Alexander Lyall, in his article on the classification of cases of albuminuria (July 26, p. 113), again raises the rather vexed question of so-called orthostatic albuminuria. While agreeing with all the hypothetical causes he suggests (they at least cannot be disproved) I should like to suggest one more possibility. Often in routine examinations for insurance, etc., I have come upon this phenomenon and have almost always elicited a history of masturbation. To prove this as the cause of the albuminuria is simple: it is only necessary to get two specimens from the patient—one immediately or soon after masturbation and one where the bladder has been emptied between masturbating and obtaining the specimen. As the patients are usually told to bring a morning specimen a trace of albumin is often found in it. Incidentally, orthostatic albuminuria is usually found in the morning specimen, and just as often represents the net result of the nocturnal eroticism.—I am, etc.,

Darwen, Aug. 3.

J. FERGUSSON.

Burns from Penetrating Bomb Fragments

SIR,—I suggest that the explanation of the delayed discharge of intestinal contents from a retroperitoneal wound of the colon, in the article by Mr. Geoffrey E. Parker (July 26, p. 119), is to be found in the observation that there was "some tissue necrosis from burning." Bomb fragments at close range are always hot

enough to produce burns. In a patient of mine who recovered from six penetrating wounds of the jejunum the fragment had come to rest in the coelomic cavity. An adjacent unperforated loop of ileum showed a white burn with charred centre, which I dealt with by infolding. Its appearance strongly suggested that had it been left it would have perforated some days later. A retroperitoneal burn of large intestine would present a different problem. It should not be infolded, but free drainage would be necessary. The site of bomb fragments in limbs is frequently indicated far from the wound of entry by the skin burn which they produce over them, and clothing carried in by fragments is often scorched so that it crumbles to dust during attempts to lift it out of a wound.

Mr. Parker suggests that his patient was lucky that he did not develop a spreading peritonitis. He would have been in greater danger of this had the peritoneum been opened. Wide drainage of retroperitoneal wounds of the large intestine is essential. The patient's life was probably saved by the early extraction of the foreign body packed in by the surgeon after he had removed the metallic foreign body.—I am, etc.,

Aug. 2.

FRANK STABLER,
Surgeon Commander, R.N.V.R.

The Envelope Treatment of Burns

SIR,—Those who tried the Carrel-Dakin method of treating wounds in the last war will remember that occasionally from about the fifth to the twelfth day the patient would suffer from malaise and become tinged lemon yellow. Both skin and conjunctivae were affected. The urine was normal. There was frequently a rise of temperature to 101° F., and the liver was sometimes tender. The signs subsided in two to three days on discontinuing the hypochlorite. Whether this condition will occur when electrolytic or a stabilized hypochlorite is used, or only with that produced by ordinary chemical means, is not known to me, but it seems opportune to draw attention to the matter.—I am, etc.,

London, W.1, July 31.

G. H. COLT.

The Darning of Hernias

SIR,—I was interested to read Mr. G. Stafford Mayer's letter (August 2, p. 176) on the darning of hernias. I am sure the majority of surgeons are now agreed that Bassini's operation and its many modifications leave much to be desired, and that "darning" with some suitable material gives much better late results. I feel, however, that some of the objections which Mr. Mayer raises to Gallie's operation are totally unfounded—in my experience at least.

There is no need to make a long wound in the thigh or to stitch the edges of the fascia together after taking the required number of strips, nor, in my experience, are fasciotomes "most tricky instruments to use," as Mr. Mayer suggests. During the last year I have performed Gallie's operation in ninety-five cases, and never once has the fasciotome given any trouble, nor have I had to employ a tenotome to free the end of the strip. The fasciotome I always employ is that designed by Mosley, and the fascia is obtained by making a transverse incision on the outer aspect of the right thigh (the instrument being easier to use on the right side) about two inches above the upper border of the patella; the incision need never be longer than three inches. The fascia lata is cleaned with a swab soaked in saline, and is then incised transversely in the line of the skin incision. The fascial strips are then taken by means of the fasciotome, and with care six or even seven strips each 1/4 inch wide can be obtained from one thigh, and not a "maximum of four," as Mr. Mayer states. It is very seldom that one requires more than three strips for even a direct hernia, so that it is possible to obtain sufficient fascia from one thigh to do a bilateral repair in the average case.

As regards the danger of a haematoma in the thigh after using the fasciotome, I can honestly say that I have never once seen one. If one is worried about the possibility of a haematoma, a firm elastoplast bandage applied round the thigh at the conclusion of the operation will obliterate the potential space to which Mr. Mayer refers. Personally, I take the fascia before exposing the hernia, but leave the sewing up of the leg wound until the very end of the operation. This gives me the opportunity to "strip" the thigh downwards and remove any extravasated blood before finally stitching up the thigh and applying the elastoplast.

I have only twice seen a muscle hernia in the thigh following removal of fascia lata, and in both these cases the fascia had been taken through a longitudinal incision over the upper end of the fascia. I believe that a muscle hernia is very rare after operation according to the method I have described. I make a point of inquiring whether the leg has given any trouble when I see my patients after they have returned to work, but have yet to get a positive answer. It is of importance to mention that the majority of my patients have been miners and labouring men, and in this connexion I remember one man (who was a lorry driver) telling me that the leg from which the fascia had been taken "felt stronger now than the left leg." My impression is that herniation is prevented by a series of strong transverse fibres at the lower end of the fascia lata, which are not disturbed or severed if the fasciotomy is guided deep to them during its stripping motion, and can be felt easily if a finger is inserted into the upper edge of the wound.

I have only had a very limited experience of silk as a repair material, but, enthusiastic as I am about the value of fascial grafts, I am equally prepared to believe that floss silk will eventually take its place.

In conclusion, I was glad to see Mr. Mayer stressing the importance of the fascia transversalis as a barrier to the posterior wall of the inguinal canal. I think its true strength is best appreciated when one has to divide it in exposing the neck of a femoral hernia above the inguinal ligament.—I am, etc.,

Edinburgh, Aug. 5.

LEWIS G. CRICKSHANK, F.R.C.S.

Treatment of Impetigo Contagiosa

SIR.—I have read Lieutenant E. Snell's letter on impetigo (August 2, p. 178) with interest. In my opinion failure with ung. hyd. ammon. dil. is due to seborrhoea in his patients, which is aggravated by the base in this ointment. I have had good results with hyd. ammon. with a vaseline base or with zinc paste: ten grains to the ounce is usually strong enough.—I am, etc.,

London, S.W.2, Aug. 4.

M. MACSWEENEY.

Sugar-free Diet and Hyperchlorhydria

SIR.—I have been very much impressed by the marked improvement in cases of hyperchlorhydria after the adoption by the patient for two or three weeks of a sugar-free diet. There are many supporters of the view put forward by the late Sir D. P. D. Wilkie that the "abdominal triad" of peptic ulcer, appendicitis, and gall-bladder disease are all caused by a bacterial infection, which is frequently streptococcal. Rosenow¹ laid stress on the important part which the streptococcus plays in gall-bladder disease, and his work has been confirmed by Hingworth² and A. L. Wilkie.³ Even those who do not agree with this view will admit that there is often a dramatic improvement in a duodenal ulcer following the removal of a chronically inflamed appendix.

While it is obviously absurd to expect a change of diet to cure a chronic appendicitis or cholecystitis with gall-stones, it is only reasonable to remember that these are the end-results of an infection which may have been present for several years. These cases are enormously outnumbered by indefinite cases of so-called chronic indigestion, to which it is impossible to give a definite name but which may, in this view, be regarded as the early stages of an intestinal infection that may or may not end in a condition demanding intervention by the surgeon.

It is interesting to observe that many of the diets recommended for acute peptic ulcer—for example, starvation for a few days, milk at short intervals, and even minced raw beef—have one feature in common—namely, the withholding of sugar—and it might be that some part of the improvement is due to the alteration in the intestinal bacterial flora brought about by the absence of sugar as well as the more obvious advantages of these diets. Additional evidence might easily be obtained from the improvement in symptoms of "chronic indigestion" which might be expected when cases of diabetes have been on a sugar-free diet for two or three weeks, in the absence of focal infection in these cases.

Cane or beet sugar only occurs in Nature diluted with large amounts of vegetable matter. In its refined or concentrated state it is an almost universal article of diet, and many children

develop gastro-intestinal catarrh or "mucous disease" through over-indulgence.

May I suggest that there are reasonable grounds for inquiry into the effect of sugar in the diet on the incidence and treatment of certain abdominal disorders—namely, "chronic indigestion," peptic ulcer, appendicitis, and gall-bladder disease—which some view as being the result of a streptococcal infection in a large percentage of cases?—I am, etc.,

St. Faiths, Norfolk, July 28.

Diagnosis of Yellow Fever

SIR.—In the *Journal* of August 2 (p. 171) the following unadorned statement appears in the general discussion after Dr. G. M. Findlay's address at the annual general meeting of the Royal Society of Tropical Medicine and Hygiene: "The absolute impossibility of diagnosing yellow fever on clinical grounds was stressed." To those who remember the worship of that golden calf, *Leptospira icteroides*, for many years, during which the brilliant work of the American Commission under Major Walter Reed seemed to be thrown on the scrap-heap, a protest is necessary.

All observers agree on the difficulties of clinical diagnosis but to state that it is "absolutely impossible" is absurd. Experts have pointed out the great importance of the diagnosis of the first case in any outbreak, and on this early recognition depends to a great extent the effect of local preventive measures. It is to be hoped, therefore, that clinical observers will not allow themselves to be discouraged by this bogey, which is raising its head by no means for the first time.—I am, etc.,

R. N. HERSON.

Novocain Injection in Myalgia

SIR.—I was very interested in the letter by Lieut. M. Good (August 2, p. 175), in view of the following case which I have treated with novocain for myalgia according to the method advocated by Lieut. Good.

A woman of 43 has suffered from myalgia in several localities, but in particular in the region of the left trapezius and deltoid. She had severe pain down the left arm. I found a very tender and well-localized area in the deltoid close to its acromial origin. On inserting the hypodermic needle here she complained of severe constricting pain in the chest of such a nature as to be unbearable. She became pale and her pulse rapid. After persevering with the injection the pain disappeared, and she had marked relief from myalgia and was able to move the arm more freely. When the effects of the injection had worn off she had a return of the pain in the chest for about twenty-four to thirty-six hours, and volunteered the information that she was sweating in the left palm. This I confirmed by examination.

Since then the patient has had marked relief from her myalgia, and neither the pain in the chest nor the increased sweating of the left palm has recurred. There was no history of pain in the chest previous to this injection. The patient is not of the nervous type, and I had injected a myalgic area on her on a previous occasion.—I am, etc.,

Communal Feeding in Schools

SIR.—I am very glad that you found space for your correspondent's article on the need for an obligatory midday meal in schools (July 26, p. 133). There is perhaps no single act which could contribute so much of permanent value in education, and the author's argument that war has converted something highly desirable into a necessity seems incontestable.—I am, etc.,

Leicester, Aug. 4.

DUNCAN G. LEYS, D.M.

Obituary

DUNCAN FORBES, M.B.E., M.D.

Late Medical Officer of Health, Brighton

We regret to announce the sudden death in London on July 25, after an operation, of Dr. Duncan Forbes. A distinguished sanitarian, he was for many years medical officer of health and school medical officer for the County Borough of Brighton.

Duncan Forbes had a brilliant record as a student of the University of Edinburgh. He graduated M.B., Ch.B. with honours in 1898, took the B.Sc. in public health in 1901, and the Cambridge D.P.H., and was awarded high commendation for his Edinburgh M.D. thesis, which was accepted after he had worked for two years as Crichton scholar in pathology; he was also awarded a special certificate in tropical diseases by the University of Edinburgh. He served as resident physician at the Royal Infirmary of Edinburgh, and as resident medical officer at the Monsall Fever Hospital, Manchester, and then in 1902 became assistant M.O.H. for Manchester. Three years later he was appointed M.O.H. for Cambridge. His long and fruitful career in public health administration at Brighton began in 1908. He had been a member of the council of the Royal Sanitary Institute, an active Fellow of the Society of Medical Officers of Health, and examiner in public health for the Edinburgh M.B. In recent years he contributed to the *Lancet* papers on water-borne diseases, on vaccination in the control of small-pox, and on exclusion from school of measles contacts.

For the following appreciation we are indebted to Sir ARTHUR NEWSHOLME, who preceded Dr. Forbes as M.O.H. for Brighton, and was afterwards Principal Medical Officer to the Local Government Board:

I only came to know Duncan Forbes well after he became my successor at Brighton; but already I had (as an examiner at Cambridge) known him enough to realize his qualities: and I had some slight influence in securing his election at Brighton. For Brighton his appointment was invaluable. He had the qualifications, mental and moral, which are specially needed for such a post. It is difficult to summarize those qualities satisfactorily when one is an octogenarian, but the characteristics which stand out in my mind are integrity and originality. He never disguised his views of desirable policy though it might be unpopular, and in some instances—as in housing of the people displaced from slum property centrally rather than peripherally—his views did not always find acceptance. From the point of view of those displaced he was right. I recall one instance in which integrity and scientific accuracy were conjoined. It required courage to discard and abandon much of the elaborate technique involved after a case of infectious disease. He was among the earliest sanitarians in this country who realized that what was to be feared was persons, not things; that persons infected about the infection they had acquired; and that articles of household furniture were usually neglected except for what may be described as a meticulous "spring cleaning." In this discovery his name stands alongside of that of Dr. Charles Chapin of the City of Providence, U.S.A. Perhaps they acted independently. I knew them both intimately; and it is right that the names of Chapin and Forbes should be remembered in this practically important research.

THOMAS GIBSON, M.D.

Late Professor of Pharmacology, Queen's University,
Kingston, Canada

Dr. Thomas Gibson, who died on July 2 at the age of 76, had been for many years a member of the British Medical Association. He occupied an important place in the life of Canada as physician in Ottawa and professor in Kingston.

Thomas Gibson was born at Strabane, County Tyrone, Ireland. His father, James Gibson, was a Presbyterian minister; his mother, Hannah McLean, came of a family which had emigrated from the western isles of Scotland to Australia. In 1873 the

Gibson family moved to Perth, in Scotland, where Thomas attended the local high school and later on the collegiate school in Edinburgh. In 1884 he graduated M.A. at the University of Edinburgh, and in 1894 M.B., C.M. with first-class honours. For six months he acted as house-physician to the late Sir James Affleck.

Dr. Gibson (writes a colleague in Kingston) came to Canada in 1895 as medical A.D.C. to the late Lord Aberdeen. In 1898 he started practice in Ottawa, where he was medical attendant to four successive Governors-General, and where he built up a large practice. In the same year he married a daughter of the late Rev. Dr. George Carey of St. John's, New Brunswick. Many of those still living in Ottawa will remember Dr. Gibson as a sympathetic, kindly, and skilful family physician. While in Ottawa he was attached to St. Luke's, the Maternity, and Water Street Hospitals. In 1924 Queen's University was looking for a teacher of therapeutics and pharmacology. Realizing that the person best fitted to teach the action of drugs to the medical student was a man with wide experience in the application of these drugs in general medical practice, the trustees appointed Dr. Gibson to the Douglas Chair of Therapeutics and Pharmacology. With characteristic thoroughness, and before taking over his professorial duties, Dr. Gibson spent some months in England, working under Prof. W. E. Dixon at Cambridge. For fourteen years Dr. Gibson was responsible for the teaching of his subject to Queen's students, and during this period he built up a department second to none in the university. There was no more popular professor in the medical college. In 1934, feeling the need of additional help in the department, he secured the appointment of Dr. Eldon Boyd, an able pupil, as his assistant. It was natural, therefore, that on his retirement from the chair in 1938 he should hand over his duties to Dr. Boyd. Although he gave up the teaching of pharmacology at this time, he continued to lecture upon the history of medicine until the end of the session just now completed.

Dr. Gibson was a true humanist. He was interested not only in medicine but in music, and was also a keen student of English literature and an appreciative collector of good prints and paintings. His own literary and historical writings include a valuable study of the work and influence of Theodore Mayerne, physician to the Royal Family in the time of James I, published in the *Annals of Medical History*. He wrote also a history of Kingston General Hospital and several articles dealing with the early years of Queen's Medical School. He had a remarkable faculty for delving among old records and periodicals and extracting from them relevant information.

Dr. Gibson was the honorary secretary of the central board of the Victorian Order of Nurses from 1898 to 1920 and its president from 1920 to 1922. In recognition of his pioneer work in the institution he was in 1911 given rank in the Order of St. John of Jerusalem. He was a foundation Fellow of the Royal College of Physicians in Canada and a member of several learned societies.

J. S. GRAY, M.B., and J. P. GORE GRIMES, M.B.

Every one of the heavy air raids on Coventry has left its scars, wounded, and dead. In April the Coventry and Warwickshire Hospital was well within the target area and suffered the full weight of the terrific bombardment, and among those who lost their lives untimely while on duty were Drs. J. S. Gray and John P. Gore Grimes.

Dr. Gray, a native of Edinburgh, received his education at George Heriot's School and at Edinburgh University, graduating in July, 1939, as M.B., Ch.B. His prowess at golf achieved for him a place in the university team, and he was also awarded his "green." Shortly after graduation he went to the Coventry and Warwickshire Hospital as house-physician, and showed outstanding ability. His second appointment was that of senior resident in charge of the resuscitation wards and an assistant in a department of pathology. He was particularly interested in haematology, and under the supervision of the director of the laboratories devoted much of his time and energy to developing the excellent blood transfusion service. Dr. Gray had been on duty throughout all the major raids on Coventry. Earlier on the fateful night he received a serious hand injury, but without

thought of his personal welfare he refused to leave his wards, and subsequently received further injuries which proved fatal.

Dr. Gore Grimes, a native of Dublin, entered Trinity College, Dublin, from St. Gerard's School, Bray. In 1934 he joined the medical school of Dublin University and graduated M.B., Ch.B. in 1939 with honours. He swam for the water-polo team of Trinity College, and represented the Dublin University Yacht Club in several events. After graduation Dr. Gore Grimes held resident posts in Dublin and also did postgraduate work at the Rotunda. In England he was house-surgeon to the Children's Hospital, Birmingham, before going to the Coventry and Warwickshire Hospital as a house-physician. This appointment he took up just before the bombardment of Coventry in November, and in his short stay he was observed to be keen, diligent, and sincere in all his work. His untiring work on the night of April will never be forgotten.

These men (writes the Resident Surgical Officer) were our colleagues; their willingness to help, their unselfishness, and their popularity with all of the Coventry and Warwickshire Hospital are still in our minds. Their careers, cut short so early, indicate in some measure to what heights in the profession they might have climbed, but they died with so many patients to whom earlier in the night they had carefully administered the healing art.

PROF. A. J. CLARK

Brigadier E. M. COWELL writes: One morning during the last days of the Battle of Flanders, 1940, I was, when driving, stopped by an orderly on a motor cycle, who had been sent out by his officer to look for medical help. I agreed and followed my guide. After repeated halts, in the nature of evasive action against dive-bombing, I entered a rather knocked-about building in Hazebrouck and found Colonel Clark acting as a medical officer to the garrison, which was fighting a desperate delaying action. He was very tired, as we all were, but cheerful and doing his best for many severely wounded. Colonel Clark served in France from 1939 till he came away off the beach at Dunkirk, and he occupied an important advisory post at G.H.Q. His fearless devotion to duty and humanitarian efforts should provide a lesson for all of us in the medical profession.

Dr. HENRY LANGDALE died at Stanley House, Warrington, on July 27, aged 74 years. He was a student of Owens College, and qualified M.R.C.S., L.R.C.P. in 1888, taking the M.B. and M.D. degrees of the University of London in 1893. Before starting his career at Warrington, where he became consulting physician to the Royal Infirmary, he had served as house-surgeon at the Manchester Royal Infirmary. "W. E. B." writes: The death of "John" Henry Langdale has deprived Warrington medicine of its best link with the nineteenth century, for after being house-surgeon at the infirmary he bought a well-established practice in the town in the middle of the 'nineties. He had been in active practice, and was often to be seen cycling on near-by visits until a month of his death. His personal interest in and friendship for his patients were unbounded; in fact he had few interests besides them and books. A serious illness fifteen years ago prevented his taking an active part in medical affairs with his colleagues, but before that time many of them had cause to appreciate his kindly and willing help. He leaves a widow, a daughter, and a son. Dr. JAMES BENNET also sends the following appreciation: Dr. Langdale's medical colleagues in Warrington and district feel a great sense of loss now that the senior member of the medical profession in this district has "passed on." A man of few interests outside his own profession, he was the very embodiment of all that is best in the true family doctor tradition, to which my own family bears grateful testimony. He came to Warrington only a few months short of fifty years ago as junior house-surgeon, subsequently becoming senior, and it was not surprising that he afterwards decided to stay on in the town in which he had already become known as a competent physician and surgeon and had earned the good will of both the infirmary board and the public. He remained an honorary physician at the infirmary for many years, and was the oldest member of the British Medical Association in this area. Having further extended a high-class practice taken over from the late Dr.

Sherratt, to whom he had been assistant, he considered it to be in his best interests not to participate in the panel scheme when the N.H.I. Act came into being; but as a consultant to panel practitioners he was in great demand. For over forty years, up to the time of his death he was medical visitor to the mental deficiency homes of the West Derby Hundred and to the Haydock Lodge Private Mental Home, where it was my privilege to meet him quarter after quarter, and I can therefore vouch for the very high esteem in which he was held by all the visiting magistrates. Cultured and courteous, Dr. Langdale set a very high standard, never spared himself, and, being a man of intense kindness, had as a reward the esteem and affection of his patients and his medical colleagues.

Dr. RODERICK MURDOCH MATHESON died at his home in Edinburgh on July 31. He was educated at the University of Edinburgh and the School of Medicine, and graduated M.B. C.M. in 1893, proceeding M.D. (with commendation) four years later, taking for his thesis empyema and its treatment. In 1901 he contributed an article to the *British Medical Journal* on haematemesis occurring in the course of appendicitis. In 1904 he became an F.R.C.S.Ed. He held the posts of assistant surgeon at Noble's Hospital, Isle of Man, and house-surgeon to the lock wards and clinical assistant to the skin department of Edinburgh Royal Infirmary before settling in practice in Edinburgh.

The Services

NAVAL AWARDS

Surgeon Captain P. M. May, R.N. (ret.), has been awarded a Greenwich Hospital pension of £50 per annum in the vacancy caused by the death of Fleet Surgeon C. S. Facey, R.N. (ret.).

The M.B.E. has been awarded to Temporary Surgeon Lieut. F. R. Badenoch, R.N.V.R., for courage in rescue work during enemy air raids on Portsmouth.

ARMY AWARD

The M.C. has been awarded to Captain R. N. Lees, R.A.M.C.

CASUALTIES IN THE MEDICAL SERVICES

ROYAL NAVY

Surgeon Lieutenant DAVID AUSTIN PROTHERO, who was killed in action, received his medical education at St. Bartholomew's Hospital and qualified M.R.C.S., L.R.C.P. in 1935. Two years later he took the D.A. His home was at Bedford. He was a member of the British Medical Association.

David Prothero (writes "E. H. P.") was injured on duty at sea and died soon afterwards. It was characteristic of him that his first thought after the accident was for those casualties near him, and it was not until they had been attended to that he himself went down to the sick bay. David was an ideal messmate and colleague. His small figure is sadly missed in the wardroom, for in times of stress or depression he never failed to instil a more balanced outlook. He had a sound clinical judgment, and though he had specialized in anaesthetics he was a reliable surgeon. I remember him operating on a gangrenous and perforated appendix while the ship was at sea off the west coast of Africa. Though the temperature of the theatre was 120° F. and tempers were becoming frayed David remained imperturbable throughout. The patient made an uninterrupted recovery.

ROYAL ARMY MEDICAL CORPS

Missing

Captain James Edward Scott Carmichael.

Prisoners of War

Major William Stanley Sykes.
Captain Charles Donald.
Captain William Gordon France.
Captain John Buchanan Fulton.
Captain John Goodworth Jamieson.
Captain George Ross Mackay.
Captain Harold William Wykes.
War Substantive Captain Graham Forrest Hay.
War Substantive Captain Geoffrey Bertrand Leyton.
War Substantive Captain John George Munro.
War Substantive Captain Kenneth Todd.

Universities and Colleges

UNIVERSITY OF CAMBRIDGE

K. V. Earle has been approved, in absence, for the degree of M.D.

UNIVERSITY OF LONDON

UNIVERSITY COLLEGE HOSPITAL MEDICAL SCHOOL

The following scholarships, exhibitions, and prizes have been awarded at University College Hospital Medical School:

Goldsmid Entrance Scholarships.—Miss M. E. P. Hele (Newham College, Cambridge); R. J. Williams (St. John's College, Cambridge). **Goldsmid Entrance Exhibition.**—R. H. Shephard (University College, London). **Filliter Entrance Scholarship in Pathology.**—P. Shubik (University College, Oxford). **Atchison Scholarship.**—R. E. O. Williams. **Magrath Scholarships.**—**Surgery:** O. P. G. Whitfield; **Medicine:** Miss J. W. Shrimpton; **Midwifery:** Miss S. M. Luty. **Filliter Exhibition.**—Miss G. R. Briggs and R. Barer (joint award). **Tuke Silver Medal.**—J. A. Black. **Liston Gold Medal.**—O. Daniel. **Alexander Bruce Gold Medal.**—A. L. M. Christie and Miss M. Mack. **Fellowes Silver Medal.**—T. R. Fink. **Junior Clinical Surgery Prize.**—Miss J. A. Davies. **Suckling Prize in Obstetrics and Gynaecology.**—A. L. Wolf. **Ferriere Scholarship.**—H. Melhuish.

ROYAL COLLEGE OF PHYSICIANS OF LONDON

At the quarterly meeting of the Royal College of Physicians of London, held on July 31, with Sir Charles Wilson, President, in the chair, the following were elected officers for the ensuing year: **Censors,** W. E. Hume, A. C. Douglas Firth, J. A. Ryle, C. M. Hinds Howell; **Treasurer,** H. E. A. Boldero; **Harveian Librarian,** Arnold Chaplin; **Assistant Registrar,** R. Hilton.

The President announced the award of the Bisset-Hawkins medal to Sir Frederick Menzies for his work as Chief Medical Officer of the London County Council; the Baly medal to Prof. Edgar Allen of Yale University for his work on oestrogens; and the Murchison scholarship (by Edinburgh University) to Alan Guild, M.B.

Prof. J. C. Meakins has been asked to represent the College at the centenary celebration of the Queen's University, Kingston, Ontario.

Membership

The following candidates, having satisfied the Censors' Board, were elected to the Membership of the College:

C. L. Davidson, M.D., J. V. Davies, M.B., P. H. Denton, M.D., Flying Officer, R.A.F.V.R., W. Dodd, M.D., C. M. Fletcher, M.B., Stella M. Instone, M.B., G. A. Kiloh, M.D., H. Kopelman, M.B., A. D. Leigh, M.B., Captain, R.A.M.C., J. McMichael, M.D., F.R.C.P.E., Hilary F. March, M.D., H. V. Morgan, M.B., R. W. Parnell, M.B., A. M.-M. Payne, M.B., J. Reid, M.B., J. C. Roberts, M.D., R. E. Rodgers, M.D., A. Sakula, M.B., L. W. D. Scott, M.D., H. L. Sheehan, M.D., Major, R.A.M.C., Margaret D. Snelling, M.B., R. H. Taylor, M.B., J. B. L. Tomblinson, M.D., L. Watson, M.B., D. A. Williams, M.D., D. Wilson, M.B., Acting Squadron Leader, R.A.F.V.R., R. Wilson, M.B.

Licences and Diplomas

Licences to practise were conferred upon the following 196 candidates (including 27 women) who have passed the final examination of the Conjoint Board, and have complied with the by-laws of the College:

E. Adler, Brenda N. Akeroyd, G. A. Anderson, E. J. Anthony, G. O. Ashworth, W. J. Atkinson, G. A. Barclay, A. G. Beaton, M. Q. Birkbeck, K. F. Blackburn, D. W. Briggs, Jutta Brokovski, W. A. Bromley, H. J. S. Brown, H. J. M. Browne, J. P. Bull, D. W. Burgess, Katherine D. Caddick, D. Caddy, J. H. Capon, L. G. Capra, W. E. Church, I. I. A. Clarke, S. N. Cole, E. D. H. Cowen, R. A. D. Crawford, C. H. K. Daly, Valerie M. K. Davies, J. J. Y. Dawson, J. C. Day, S. R. Deenadayalu, P. J. R. Deller, P. B. de Maré, M. Diamond, J. P. Donnell, G. B. Downs, Christina N. Duigan, H. L. le V. dit, Durell, K. C. S. Edwards, R. M. Ellison, M. L. H. Evans, W. H. M. Evans, A. Feiner, H. P. Ferreira, J. C. Firth, R. B. Franks, F. E. Fraser, R. Fuller, M. Gang, V. O. B. Garside, D. S. G. Genge, J. A. Gillett, N. Gillman, C. W. Glassey, E. C. Glover, C. L. Grandage, D. McC. Gregg, H. Grylls, Joan I. Hallinan, A. P. Hardman, K. O. Harrison, J. L. G. Hartley, A. Heller, W. G. Helsby, J. A. Henderson, Joan D. K. Hilditch, C. Hinson, F. H. Howarth, G. Howells, Janet R. Humphrey, M. P. Hutchinson, E. L. Ives, B. Jackson, J. R. Jackson, P. Jacobs, C. T. A. James, Alberta M. Jeans, E. R. Jones, Evelyn A. Kaye, B. Kelion, S. K. Kelleit-Smith, G. R. Kershaw, C. A. King, Doreen H. King, M. D. King, F. Kohn, Celia P. Larkins, W. S. Lewis, Ursula M. Lister, H. C. Llewellyn, Sophia Lucas, G. M. Lunn, Stella M. Luty, J. Lyons, J. M. McCurdy, J. L. B. MacFarlane, Joan Mack, Sylvia I. E. Macmillan, J. M. H.

McMurray, T. E. L. J. McNair, A. D. A. Machonochie, F. M. McRae, M. Makin, E. A. de la T. Mallett, J. A. Mantle, W. J. C. Markby, D. E. Marmion, A. H. E. Marshall, S. A. Mason, J. P. Matthews, P. H. N. Matthews, Violet D. Maxwell, R. J. Melhuish, S. L. Melville, A. R. H. Mills, D. V. Milward, F. S. Moore, T. K. Morgan, F. P. Morris, G. A. Mott, R. A. Nabi, D. L. Nichols, J. A. B. Nicholson, H. H. Nixon, J. F. North, A. O'Connor, P. H. Ogilvie, D. J. O'Meara, T. M. Li. Owen, H. Paradis, T. E. Parry, J. H. Peacock, M. T. Pheils, J. H. C. Phillips, L. G. Piccinini, G. H. Pickering, R. J. F. H. Pinsent, R. J. Pitchford, Peggy O. M. Plews, A. Poteliakhoff, C. Reichman, Margaret E. Rhodes, C. W. Richards, G. K. Riddoch, T. B. Li. Roberts, Dorothy H. Robertson, J. A. Robertson, E. Robinson, A. C. Rogers, M. Rosten, B. Sam, C. S. Savage, G. P. A. Sechiani, J. A. Segal, J. Seiler, B. A. Sellick, J. Shah, O. H. C. Shelswell, J. J. Shipman, M. Shoham, G. Skinner, H. Souster, Eirian Spickett, J. M. Stansfeld, A. W. P. Stone, T. P. Storey, C. G. Stringer, A. Tay, G. G. Taylor, J. G. Taylor, A. E. Thomas, E. F. Thomas, M. G. B. Thompson, Joan M. Thornton, J. P. Turney, G. K. Tutton, A. B. Unwin, Carolina M. van Dorp, C. T. Vincent, W. J. K. Walls, J. A. Ward, K. O. Warner, R. P. Warren, P. C. Watson, Mary E. Wehner, E. Wellisch, Alison D. Wells, L. Wertheim, F. T. Wheelodon, A. H. Widdup, H. L. J. Wilson, J. R. J. Winter, P. H. Wood, R. C. Woolls, G. A. Yorke, Mary Young.

Diplomas in Anaesthetics were granted, jointly with the Royal College of Surgeons of England, to the twenty-two candidates whose names were published in the report of the meeting of the Royal College of Surgeons of England in the *Journal* of June 21 (p. 949), and Diplomas in Laryngology and Otology (four), Psychological Medicine (eleven), and Public Health (six) were granted to the successful candidates whose names were published in the report of the meeting of the Royal College of Surgeons of England in the *Journal* of July 19 (p. 105).

The following diplomas were also granted, jointly with the Royal College of Surgeons of England:

DIPLOMA IN MEDICAL RADIOLOGY.—G. W. Blomfield, Mary A. C. Cowell, A. Fry.

DIPLOMA IN OPHTHALMIC MEDICINE AND SURGERY.—K. A. Abayomi, H. C. Black, P. A. Gardiner, J. Halperin, L. H. Lake, T. A. Narayanan, Jean M. G. Shaw, J. L. S. Steele-Perkins, D. Turner.

Medical Notes in Parliament

On August 7 the Royal Assent was given to the Pharmacy and Medicines Act, as also to the National Health Insurance, Contributory Pensions, and Workmen's Compensation Act.

Pharmacy and Medicines Bill

On August 5 the House of Lords considered the Pharmacy and Medicines Bill in Committee. After technical amendments to Clauses 1 and 2, the LORD CHANCELLOR moved an amendment to Clause 8 (Disclosure of composition of medicines). He said that the clause as printed in the Bill provided that the article recommended as a medicine must have a label to show "the appropriate designation of the substance so recommended, or of each of the active constituents thereof." Anxiety was expressed, more particularly on behalf of the herbalists, that this might be taken to mean that they had to state what were the chemical constituents in the bottle, notwithstanding that there might be quite serious changes after the contents had been put together. That would be putting on the herbalist too severe a burden. The amendment was agreed to.

On Clause 9 (Restriction of sale of medicines by unauthorized persons) Viscount PLUMER moved an amendment which, he said, described the processes commonly used in the preparation of herbal medicines, but which were not mentioned in the Bill. The protection given in the clause to herbalists did not go far enough. There was nothing to permit the use of a liquid process which was necessary for the production of many tinctures, essences, and oils commonly used by the herbalist and sold by him in his shop.

The LORD CHANCELLOR said the amendment was too wide. In the end it would lead to the production of an unlimited number of medicines whose efficacy depended on their chemical constituents produced under the alleged shelter of dealing with herbs and herbal extractions. Lord HORDER said that the House had given the herbalists a certain amount of what they had asked for. Now they were asking that certain processes should be permissible in preparing those ingredients which were calcu-

lated, he believed, inevitably to result in so changing and confusing the ingredients as not to make it possible to state finally what they were. This was an effort to side-track one of the two main principles that the Bill established.

Viscount PLUMER moved another amendment dealing with the use of preservatives. He explained that it was impossible to produce a herbal medicine without some form of preservative. His amendment dealt with the addition of glycerin, alcohol, and esters of parahydroxybenzoic acid, "or such other preservative as the Ministry of Health might sanction." The LORD CHANCELLOR, resisting the amendment, said that if alcohol were used as a preservative in these cases a proportion of something like 20% of the whole mixture would probably be necessary for that purpose. Alcohol might, in fact, result in the preparation of a tincture which would be a manufactured article quite remote from the simple herbal remedy, and one having wholly different results. Lord HORDER, who also opposed the amendment, said it was very pertinent to note that no quantity or minimum amount of glycerin, alcohol, and other alcoholic preparations for use as preservatives was suggested. The action of these preservatives on the questionable derivatives remaining after macerating, infusing, boiling, and so on was such as to render the principle of the Bill, which called for disclosure, of no effect. The amendment was negatived.

The LORD CHANCELLOR moved an amendment to make it plain that the phrase in Subsection (5) (a), "the substance recommended as a medicine which the article consisted of or comprised," meant the whole substance contained in the article—the bottle of cough mixture or whatever it might be—and did not refer to each one of the constituents of, for example, the cough mixture.

The Committee stage was concluded. On the Report stage an amendment by Viscount BERTIE which, he said, would enable the Ministry of Health to give that help to herbalists with regard to preservatives which they so badly needed, was withdrawn. The Bill was read the third time, passed, and sent back to the House of Commons.

On August 6 the House of Commons agreed with the Lords' amendments to the Pharmacy and Medicines Bill. Miss HORSBROUGH explained that certain of these had been drafted to reassure the Society of Herbalists, whose representatives had come to the Ministry of Health a few days previously and put their difficulties before the Department.

Mr. VIANI asked the Minister of Health on July 30 to consider the position of naturopaths not retailers of herbs who prescribed for their patients, and sold tinctures, fluid extracts, and compressed tablets under the Pharmacy and Medicines Bill.

Mr. BROWN replied on August 7 that this Act did not affect the right of these practitioners to provide treatment for their patients.

Scotland's Health Services

Introducing the Estimates for the Department of Health for Scotland on July 30, Mr. T. JOHNSTON said that in the past year Scotland had escaped a major epidemic. Figures for tuberculosis were increasing, those for diphtheria were higher than ever, and those for paratyphoid, cerebrospinal fever, and influenza were slightly up. Scarlet fever, measles, and whooping-cough were decreasing. Causes of the increased incidences were the black-out, windows fastened at night, overcrowding due to evacuation, intensification of toil, and above all the long and severe winter. The campaign for immunization of children against diphtheria had been given publicity, materials had been supplied to local authorities gratis, and 500,000 children—half the total—had been treated during the year. Local authorities had been asked to concentrate their attention during the holidays upon pre-school children, whose susceptibility was greater. Mr. Johnston agreed that a larger proportion of the beds in the Emergency Hospital Service should be taken for civilians who were on the waiting lists of other hospitals. The emergency service had seven first-class hospitals and twenty new annexes to existing hospitals. The Department of Health had drawn the attention of every doctor and of all hospital authorities in Scotland to the fact that it was willing to see a large proportion of their waiting lists. He hoped those seven hospitals would be the nucleus of great service not alone for citizens in the areas where they had been built. This, with the stimulus of the

Nuffield Trust, should remove the waiting lists and demonstrate the wisdom of co-operation in wide areas among hospital authorities, municipal and voluntary.

Mr. MAXTON asked Mr. Johnston to ensure that the cheap or free milk provided for the child under 5 was continued till the child received the school ration. Colonel ELLIOT said the hospital waiting lists had always been a scandal in Scotland. A person might have to wait for years for admission, and the same problem existed in the North of England. He was glad a big addition had been made to hospital accommodation. The increasing incidence of some diseases mentioned by Mr. Johnston was a warning that strain and stress were beginning to have an injurious effect on the constitution of the people. Both in Scotland and England the graphs of tuberculosis had turned upward after a long decline, which showed that close consideration should be given to nutrition.

Dr. MORGAN said there were still areas in Scotland where no organized fracture treatment was given, such as the Glasgow Royal Infirmary. Although this had an excellent clinic, treatment was completely dissociated and unorganized in the in-patient departments. Could not the Government, by grants to voluntary hospitals, introduce proper organization in both the in-patient and out-patient departments and bring these hospitals up to Grade I as laid down by the Delevingne Committee? In Scotland in 1939 only one hospital—the Glasgow Hospital—was carrying out the treatment laid down for Grade I. Three hospitals were in Grade II, none in Grades III and IV, and six in Grade V. Many dissociated rehabilitation from treatment and did not adopt it until surgical treatment was complete.

Replying for the Government, Mr. WESTWOOD said the annual report of the Department of Health had been suspended during the war, but a rough summary report would soon be available to members. Beds were available in auxiliary hospitals, and there was no justification for a waiting list. He knew of the difficulties of the medical profession, who sometimes did not want to send their work to another hospital.

The House agreed to the Estimates for the Department of Health, and also for a token Estimate for services in that Department arising out of the war, including measures in Scotland to deal with casualties and disease.

Medical Problems of the Ministry of Pensions

Estimates of £37,003,000 for the Ministry of Pensions were discussed on July 31. Introducing them, Sir WALTER WOMERSLEY said consideration had been given to the position of men who, having been passed by a recruiting board on enlistment and placed in Grade I as fit for general service, were, after effective service, discharged on account of a disability shown to have existed before enlistment. Doctors usually referred to this as a constitutional disease. He had concluded that where effective service was found to have caused aggravation in a previously existing condition, and where the man had not given the board untrue information about medical facts known to him, the Minister would be justified in regarding the aggravation as material and as bringing the case within the scope of the Royal Warrant. Under the new rule, if the doctors who examined on behalf of the Navy, Army, or Air Force had made a mistake, then the State must pay. Many cases were being reconsidered, and he hoped that all would be cleared up before long. He had secured an amendment of the Royal Warrant to give him discretion to make a reduced or even a full award where the death or disablement of a member of the Forces involved an element of negligence or misconduct. He would provide by Royal Warrant that a man in the Home Guard, when on duty, came under the same regulations as a member of the armed Forces. Hospitals under the Ministry now had a bed strength of 7,647, against 1,833 at the outbreak of war, and an additional hospital of 600 beds was nearing completion. Some hospitals had suffered severely by bombs, and in every case the staff showed bravery and zeal. The staff included 285 medical men, 100 on a part-time basis. They were all rendering splendid help. During the past year in-patient treatment was given in 5,300 cases, and 5,267 officers, nurses, and men received treatment in mental hospitals. In addition 6,605 Service and civilian casualties received treatment in Ministry of Pensions hospitals. The Government was considering the rehabilitation and training of men discharged from

Medical News

Dr. Frederick Wharton, a surgeon of Lexington, Kentucky, has been elected president of the American Medical Association.

The Home Secretary has appointed Sir Robert Kelly to be a member of the Advisory Committee on the administration of the Cruelty to Animals Act, 1876, in place of the late Sir D'Arcy Power.

Major Alexander Wilson, O.B.E., M.D., has been appointed a Deputy Lieutenant for the County of London.

Jaconet (as defined by the *British Pharmaceutical Codex*) may be obtained coupon-free if sold in pieces not exceeding forty-five inches in length or breadth.

According to the *Schweizerische medizinische Wochenschrift*, a census of persons suffering from venereal disease in Germany carried out in June, 1940, showed that there were, in round numbers, 122,000 men and 75,000 women. These figures imply that the usual increase in these diseases in wartime had not then taken place.

The distinguished service medal for scientific achievement of the American Medical Association has been presented to Dr. James Ewing, formerly director of the laboratories of the Memorial Hospital, New York.

A pamphlet on family allowances, by Mrs. E. M. Hubback, issued by the Family Endowment Society (19, Wellgarth Road, N.W.11) provides an up-to-date short statement on the case for the immediate introduction of a State-paid scheme of family allowances. Its purpose is to show the impracticability of dealing with child poverty among larger families in any other way, especially in wartime.

The Narcotics Division of the League of Nations has been moved from Geneva to Washington.

We regret to announce the death at the age of 85 of Sir Alfred Rice-Oxley. We hope to publish a memoir in our next issue.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, W.C.1.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated.

Authors desiring REPRINTS of their articles must communicate with the Secretary, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors over-seas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

ADVERTISEMENTS should be addressed to the Advertisement Manager (hours 9 a.m. to 5 p.m.). Orders for copies of the *Journal* and subscriptions should be addressed to the Secretary.

TELEPHONE NO.—B.M.A. and B.M.J.: EUSTON 2111.

TELEGRAPHIC ADDRESSES.—EDITOR, *Aitiology Westcent, London*; SECRETARY, *Medisecra Westcent, London*.

B.M.A. SCOTTISH OFFICE: 7, Drumsheugh Gardens, Edinburgh.

QUERIES AND ANSWERS

Timepiece for Blind Person

"INQUIRER" writes: Can any reader give advice as to a suitable timepiece for an old lady who has recently become blind? Her intelligence is good but adaptability only fair. She gets very agitated at not being able to tell the time.

Diminution in Size of Breasts after Childbirth

Dr. H. D. MOORE (Carlisle) writes: I have a patient whose breasts have become rather shrunk and pendulous after childbirth. She is a young woman of 23; first child 6 months, unable to breast-feed it, although efforts were persisted in. Her general health has not been very good. She has lost a little weight—about 6 lb.—and has had a cough, which is now quite well: tuberculosis has been excluded. She is worried about this. Can anyone suggest any treatment, apart from general methods, to improve her health and put on weight?

Income Tax

Travelling Expenses

"G. H." received £260 in medical fees for work under the Military Training Act. Attendance at the board necessitated travelling fourteen miles on each occasion. The £260 was his only earnings for 1940-1. The cost of travelling has been refused.

** As we understand the position, "G. H." accepted an appointment which necessitated attendance at premises some distance away, and his work was carried on there. Such expenses have been judicially held to be incurred before or in preparation for carrying out the duties of the employment and not (as required by the statute) "wholly, exclusively and necessarily in the performance of the duties." They are, therefore, not allowable as deductions. In the result "G. H." may not unnaturally feel that he is placed under hardship—a feeling which the large body of employees who live in suburbs and work in the centres of crowded areas fully share. In a recent debate, however, the Chancellor of the Exchequer said he was unable to redress the grievance.

Sale of Practice: Instalment Payments

"BETA" is arranging to sell his practice at one and a half years' purchase—that is, "50% of the income from the practice for each year for three years." If that is done how will income tax be affected?

** "Beta" should see that the agreement for sale of the practice is expressed in such a way as to make it clear that the practice is being sold for a capital sum to be satisfied by payment for three years of 50% of the gross income. If that is done the payments will rank as capital sums and will not be taxable in his hands. The deciding case on the point is *Commissioners of Inland Revenue v. Ramsay*.

Deduction for Nominal Rent

"A. P." owns his residence, which is assessed at £64 for payment of income tax, Schedule A. There are twelve rooms, of which four are used for professional purposes. What amount should he charge in his professional accounts as "rent"?

** As the rent is treated as £64 net for payment of income tax, Schedule A, he must take that as a basis for calculating the deduction. The four rooms used professionally are presumably on the ground floor—that is, the most valuable floor—and possibly do not include the garage. On the whole, one-half of £64—that is, £32—seems to be a reasonable deduction. (It is assumed that the cost of repairs, decorations, etc., of the professional rooms is charged separately.)

LETTERS, NOTES, ETC.

Flat-foot in Recruits

Dr. W. F. BENSTED-SMITH (Newton Ferrers) writes: I can endorse the results quoted by Captain Sachs and Lieut. Gibson (July 26, p. 127) from the use of rubber as a support. I have for some years used pads shaped from rubber sponges and held in position by adhesive or sewn into socks for bad flat-foot in farm workers and ploughmen (a comparable class) with most cheering results.

The Unburned Cornea

Dr. ARTHUR GREENE (Norwich) writes: In the *Journal* of July 12 (p. 74) under the above heading, after a reference to one of Jules Verne's wonderful books, attention is drawn to cases of patients whose corneas have escaped serious injury though enveloped by molten metal. 'One would scarcely expect such good luck in the case of a chemical burn, but, a good few years back now, I was called urgently to see a boy (aged about 16) whose eye had just been injured by an explosion while working in the school chemical laboratory. My horror can be imagined on recognizing the boy as one who, I knew, had lost the vision of one eye some nine years previously, and that it was the "good eye" which had received the chemical. The entire cornea was covered up by a dark and adherent rough mass, for all the world like a piece of charcoal moulded to the cornea. Although, fortunately, I had not the courage to say so, I thought it obvious that he was doomed to permanent blindness. The eye made an excellent recovery, and when last I heard of him he was holding an important business position "out East." A prognosis as regards vision should never be given at the first examination of an eye burned physically or chemically, especially a "lime burn," which, though it may look trivial at first, frequently leads to severe visual defect.

The Editor of the *Medical Directory* asks members of the medical profession who have not communicated to him their present addresses to do so without delay, otherwise the words "Address unknown" will appear in lieu of an address in the forthcoming 1942 edition.

AMOEBIIC DYSENTERY AND ITS EFFECTIVE TREATMENT*

A CRITICAL STUDY OF 535 CASES

BY

Sir PHILIP MANSON-BAHR, C.M.G., D.S.O., M.D., F.R.C.P.

The aim of the present investigation has been to discover the best method of treating intestinal amoebiasis and of eradicating this infection.† 535 cases have been selected for this study out of numerous records of clinical amoebiasis during a period of twenty years. Those only have been included in which *Entamoeba histolytica* or its cysts have been demonstrated by personal observation. No metastatic complications of amoebiasis have been considered unless accompanied by manifestations of active amoebic dysentery.

Of the cases 450 were in men and 85 in women; with the exception of 8 Indian seamen all the patients were Europeans. They were derived from sixty-four countries, though the great majority were from India, Ceylon, West Africa, China, and Malaya: smaller numbers hailed from other parts of Africa, from Egypt to the Cape, including the Canaries, Cape Verde Islands, and Mauritius. In Europe a few were infected in Northern France, Germany, Austria, Greece, South Russia, and Malta. From America cases came mostly from the West Indies and the South American republics. From Australia there was one example, from New South Wales; from England one indigenous infection.

This case occurred in a stevedore in the London docks who had been suffering from supposedly ulcerative colitis. He had never been out of England, but had worked for twenty years on the wharves, where he had probably contracted amoebiasis from association with Indian seamen.

Most cases originated between the second and fourth decades of life, a small proportion (43) between the fifth and sixth, and only 8 above that age. There were 8 under 20 years old, the youngest being 7½ (although the infection had been acquired five years earlier). Amoebiasis therefore appears to be mostly a disease of adult life: European children are seldom affected. It is usually contracted from contaminated water. Thus 10 in this series were employees of a cable company from St. Vincent (Cape Verde Islands), where the evidence of infection from stored and contaminated water was found to be almost conclusive.

Diagnosis

The following is a summary of the findings:

Diagnosed by <i>E. histolytica</i> in scrapings from ulcers in rectum ..	26
Diagnosed by active <i>E. histolytica</i> in faeces ..	222
Diagnosed by <i>E. histolytica</i> cysts in faeces (in 17, preystic forms together with cysts) ..	287

In many cases *E. histolytica* cysts were associated with *Giardia intestinalis*, *Iodamoeba buetschlii*, *Endolimax nana*, *Entamoeba coli*, active and cysts. In no instance were active *E. histolytica* and cysts found simultaneously in blood and mucus stools. It is important to note that in 26 cases diagnosis was rendered certain from scrapings made from

amoebic ulcers in the bowel, whereas no confirmatory evidence had been forthcoming by simultaneous faeces examinations.

Sigmoidoscopy was performed in 258 cases, amoebic ulcers and other characteristic lesions being demonstrated in 234. In 77 cases active entamoebae were recognized in scrapings; in 24 (9.3%) the mucosa had a normal appearance. Routine sigmoidoscopy has therefore proved its value as a means of securing positive diagnosis. Thus:

An officer aged 27 who had for long been regarded as suffering from ulcerative colitis was seen in June, 1934. The faeces had been examined microscopically on many occasions, with a negative result. Sigmoidoscopy revealed ulcerated mucosa, and in scraping active *E. histolytica* was seen. It transpired that up to 10 years of age he had lived in Mauritius, where he had suffered from mild dysentery, but since then had not been abroad. The latent period of this infection was therefore seventeen years.

Complicating Conditions

Many other complicating infections were recorded, such as: malaria (30 cases), kala-azar, trypanosomiasis, filariasis (*A. perstans* 3, *Loa loa* 1), ankylostomiasis, oxyuriasis, ascariasis, bilharziasis (*S. mansoni* 2), sprue (8), cardiac complications (4), *B. coli* bacilluria (5), liver abscess (6), amoebic infection of the skin (1), syphilis (4), renal calculus (3), fistula in ano, rectal abscess, fibroid phthisis, pneumonia, tuberculous mesenteric glands, etc. Two cases in which the patient was pregnant (seven months and six weeks respectively) were cured by E.B.I. treatment.

Clinical Notes

Amoebic dysentery is usually chronic in nature and erratic in its course. It is particularly benign, and seldom dangerous to life. There was only one death in this series, in a patient who was moribund when the diagnosis was made:

Though the onset of the fatal illness was sudden and death took place within three days, it is probable that the patient had been infected for a considerable period. He was a ship's carpenter who had sailed to the Tropics for many years. At necropsy extensive ulceration and necrosis of the large intestine were found, as well as five liver abscesses.

The great majority are apyrexial. Fever usually denotes subacute hepatitis, which accounted for 30 in this series, but occasionally an alarming pyrexia, which may best be termed "amoebic fever," may be noted.

A seaman on his arrival from Sierra Leone (July, 1940) had been ill for sixteen days with high fever, headache, bone pains, and other signs of toxæmia. His general condition suggested typhoid. There were occasional attacks of diarrhoea and meteorism. No amoebae could be demonstrated in the faeces, though sigmoidoscopy revealed extensive ulceration of the rectal mucosa, containing active *E. histolytica*. Response to treatment was almost immediate (see Chart).

* Based on the Lumsden Lectures for 1941.

† The results of treatment are given in a series of tables at the end of this paper.

renders the infection eventually more difficult to eradicate. The following principles may be enunciated:

1. A fresh infection is more easy to eradicate than one of long standing.
2. The widely accepted practice of periodic injections of emetine, or even inadequate doses by the mouth of other emetine compounds, is not recommended, for it has been indicated that, so far from effecting a cure, this method tends to render *E. histolytica* emetine-fast.
3. Cases, however resistant, can eventually be cured, provided the course of anti-amoebic treatment is sufficiently thorough and prolonged.
4. Quinoxyl is a potent non-toxic drug, causing few disagreeable sequelae. In resistant cases of amoebiasis it produces the most permanent results in combination with emetine bismuth iodide. This treatment is usually well tolerated, provided that minutiae of dosage and timing are observed.

Results of Treatment

TABLE I.—Showing Nature of Anti-amoebic Treatment on 276 (51.5% of the Series) previously Untreated Cases (110 with Active Amoebae and 166 with Cysts)

Emetine bismuth iodide courses of 20 to 26 grains	29
Emetine periodide courses of 28 to 72 grains with tablets of fel bovinum	9
Quinoxyl pills (4 grains), plus quinoxyl retention enemata 2½%	18
Stovarsol 80 grains (cyst-carrier case)	1
<i>Combined treatments:</i>	
Emetine bismuth iodide 20 to 26 grains, plus quinoxyl retention enemata 2½% (1 case, 5%)	198
Emetine periodide 20 to 30 grains, plus quinoxyl retention enemata 2½%	17
Auremetine 30 grains, plus quinoxyl retention enemata 2½%	4

Out of 276 cases there were only 4 (1.4%) uncured. Two definite relapses occurred one year later, and these were ultimately cured with further treatment. In 2 cases the result could not be followed up.

TABLE II.—Showing Effect of Emetine Injection Treatment on 259 (48.5% of the Series) Cases (138 with Active Amoebae and 121 with Cysts) prior to Parasitic and Clinical Relapse

Emetine injections ranging from 40 to 60 grains, given over a period of 4 to 6 months, in 2 cases reinforced by intravenous emetine	171
Emetine injections, plus 2 to 3 courses of emetine bismuth iodide, emetine periodide, or auremetine	67
Emetine injections, plus oral quinoxyl, stovarsol, carbarsone, or ipecacuanha	21

TABLE III.—Further Anti-amoebic Treatment of Emetine-injection-treated Cases Detailed in Table II

Emetine bismuth iodide courses of 30 to 40 grains	91
Emetine periodide courses of 30 to 70 grains with tablets of fel bovinum	6
Quinoxyl pills (4 grains), plus quinoxyl retention enemata 2½%	17
Stovarsol 80 grains, plus quinoxyl retention enemata 2½%	2
Emetol retention enemata	1
<i>Combined treatments:</i>	
Emetine bismuth iodide 19 to 30 grains, plus quinoxyl retention enemata 2½% (5% in 16 cases)	124
Emetine periodide 30 grains, plus quinoxyl retention enemata 2½%	17
Auremetine 30 grains, plus quinoxyl retention enemata 2½%	1

RESULTS OBTAINED IN THE SERIES OF TABLE III

Of these 259 there were 20 cases which relapsed still further, but all, with one doubtful exception, were eventually cured. The relapse rate was 7.7%. The following are typical resistant cases:

Case 1.—Infected in Tanganyika in 1917; continually relapsed after courses of emetine injections. Admitted to hospital 1920, 1922, 1923, for treatment with E.B.I., E.P.I., and ipecacuanha. Eventually cured in 1928 with full combined course of E.B.I. 30 grains and quinoxyl retention enemata 5% for ten days.

Case 2.—Infected in Nigeria in 1928; had numerous relapses in spite of emetine injections. Had amoebic hepatitis in 1935. Relapsed again after E.B.I. treatment. Eventually cured in 1936 with E.B.I. 20 grains and quinoxyl retention enemata 2½%. Reported up to 1941 in good health.

Case 3.—Had spent forty-two years in West and Central Africa. In 1925 suffered from amoebic dysentery and hepatitis,

controlled by emetine injections. In 1934 *E. histolytica* cysts were found in the faeces, and sigmoidoscopy revealed amoebic lesions. He was treated by E.B.I. 30 grains and quinoxyl retention enemata 2½%. Febrile attacks recurring in 1935, he was operated upon for cholecystitis, but instead a chronic intralobar abscess in posterior part of right lobe of liver was exposed. During convalescence an acute attack of amoebic dysentery developed, with active *E. histolytica*. This was finally cured by repeating the course of treatment with E.B.I. and quinoxyl 5%. He has remained in good health ever since. It is a matter for speculation why the treatment which appeared ineffective in 1934 was curative a year later.

AMOEBIASIS—PULMONARY COMPLICATIONS

BY

B. A. DORMER, M.D., D.P.H., D.T.M. & H.

AND

J. FRIEDLANDER, M.B., Ch.B., D.P.H.

(From the King George V Hospital for Tuberculosis, Durban)

Our experience in Natal leads us to believe that pulmonary amoebiasis is fairly common in the coastal belt, more particularly among the non-European population. It is our contention that whenever amoebic dysentery occurs pulmonary complications will be found in a high percentage of untreated cases. This is of great importance to the armies in the East. There is no doubt about the high incidence of amoebiasis in the population of Natal, as judged by the various hospital records. In 1939, for example, at the King Edward VIII Hospital for Natives, Durban, 1,520 cases of amoebic dysentery were admitted—i.e., one-tenth of the total admissions for the year. At the McCord Zulu Hospital in 1940, of 3,763 admissions 251 (6.7%) were cases of amoebic dysentery. Many of these cases had been wrongly diagnosed as pulmonary tuberculosis.

Amoebiasis of the lung may be primary or secondary. The primary form is comparatively rare: the latter form is much more frequent than is thought.

Primary Pulmonary Amoebiasis

Manson-Bahr (1940) states that in primary amoebiasis of the lung "the entamoebae reach the lung by direct embolism from the gut wall. Having gained the pulmonary circulation, they form consolidated nodules, which later break down into small abscesses."

Our cases have presented the following signs and symptoms: cough, sputum, haemoptysis, wasting, night sweats, evening rise of temperature—in fact, all those of pulmonary tuberculosis. The main points leading to a diagnosis of primary pulmonary amoebiasis were: (a) a careful history revealing no family or other known contact with a case of

active open tuberculosis; (b) a history of diarrhoea or dysentery; (c) absence of tubercle bacilli in the sputum on repeated examination; (d) the presence of eosinophilia; (e) the presence of cyst forms of *Entamoeba histolytica* in the stools. On no occasion were amoebae demonstrated in the sputum.

Treatment.—The response of primary amoebiasis of the lung to emetine and carbarsone is remarkable and rapid. Emetine hydrochloride 1/2 grain hypodermically and one carbarsone tablet (0.25 gramme) per os are given twice daily at the same time for five days. Then carbarsone alone is given per os twice daily for five days, followed by rest for five days. If the condition has not cleared, the course is repeated.

Secondary Pulmonary Amoebiasis (or Amoebic Abscess of Lung)

In secondary pulmonary amoebiasis infection of the lung takes place by direct extension from an amoebic abscess of the liver. The abscess may rupture direct into the pleural cavity, giving rise to an empyema. More often the diaphragmatic pleura becomes adherent, thus shutting off the pleural cavity, and extension of the amoebic infection takes place direct into the lung base.

Symptoms and Signs.—The patient complains of cough, and sputum which is blood-stained at times and always characteristically "anchovy-sauce" in appearance, loss of weight, loss of appetite, malaise, and night sweats. Because of these symptoms the cases are often wrongly diagnosed as basal tuberculosis, more particularly in the Bantu, since it is known that basal tuberculosis is commoner in primitive races than in the European. A careful inquiry into the previous history may elicit a previously unsuspected dysentery. On the other hand, many patients give no history of any bowel disturbances. The cough is often troublesome and the sputum profuse. A mere glance at the characteristic "anchovy-sauce" sputum should direct attention to the correct diagnosis. The absence of tubercle bacilli in the sputum would tend to eliminate pulmonary tuberculosis. Examination of the chest reveals dullness at the right base, with deficient or absent breath sounds and often tenderness in the right hypochondrium, due to the associated hepatitis.

Radiological Appearances.—In primary pulmonary amoebiasis the radiograph may present the appearance of tuberculous infiltration or a bronchopneumonic consolidation. In secondary amoebiasis of the lung there is usually a well-marked opacity at the base, with obliteration of the costo-phrenic angle and immobility of the right hemi-diaphragm. The inflammatory reaction spreads from liver to diaphragm, and the process extends then to the lung surface of the diaphragm and to the base of the lung before actual rupture into the lung takes place. The septum between the middle and the lower lobes, usually hardly discernible on the radiograph, takes part in the inflammatory process, becomes thickened, and appears as a fairly thick band limiting the inflammatory process to the base. On account of the elevation of the diaphragm from the hepatic abscess and the inflammatory products of the base, the septum usually assumes an elevated position with the convexity upwards. When the abscess ruptures into the base the thickened septum often prevents the rupture taking place into the middle lobe. From the base the abscess tends to rupture into the particular lobe bronchus or bronchi, and the patient coughs up the characteristic "anchovy-sauce" sputum. Often a radiograph will show a small pocket of air lying subjacent to the septum.

Bronchography.—This may be of value in differentiating amoebic abscess from lung abscess due to other causes,

since in the latter condition a blocked bronchus is usually found. Basal bronchiectasis is easily distinguished on a bronchogram. We have introduced lipiodol into the right lung base in several cases of amoebic abscess in an effort to show a direct communication between the lung and the liver. As yet we have not been successful in this.

Treatment.—As in primary amoebiasis, emetine and carbarsone have a rapid and dramatic effect. Where an empyema is present, drainage is necessary in addition.

The following are records of seven cases illustrative of pulmonary amoebiasis.

Case I

This patient, a European aviator aged 32, was employed by Imperial Airways and travelled up and down Africa. About eight months previously he began to complain of cough and blood-stained sputum, which has continued up to the present time. He had lost some weight and his appetite "had gone off." His weight is now stationary. There was no history of any dysentery. He was referred to the King George V Hospital as a case of pulmonary tuberculosis. His personal and family history revealed nothing of note.

On examination his general condition was good. Neither anaemia nor clubbing of fingers was present. Crepitations were heard in the left mid-zone. Nothing abnormal was found in the cardiovascular and genito-urinary systems. The sputum was negative both on direct smear and on concentration. A radiograph showed an area of infiltration in the left lung (Fig. 1).

FIG. 1.—Primary pulmonary amoebiasis. Radiograph shows fairly extensive infiltration in left mid-zone and base.

A blood count revealed a 10% eosinophilia. His stool was examined and cyst forms of *E. histolytica* were found. A course of emetine and carbarsone was given, following which there was rapid and dramatic improvement and his cough and sputum cleared up completely. A radiograph taken after treatment showed the lung fields to be clear (Fig. 2).

Case II

This patient, a native labourer aged 35, was seen at a neighbouring hospital, where he was being treated for pulmonary tuberculosis. He gave a history of cough and sputum, blood-stained at times, associated with loss of weight and energy. His

sputum was repeatedly T.B.-negative. He had also had an attack of "dysentery" some two to three months previously. His general condition was fair; he had a cough productive of much "anchovy-sauce" sputum, but no clubbing of fingers.

FIG. 2.—Radiograph, taken after one course of emetine, shows an almost complete disappearance of the original lesion.

There was dullness and poor air entry in the lower half of the right lung. The cardiovascular system was normal. The sputum was negative both on direct smear and on concentration. A blood count showed 10,000 white cells per c.mm., with an 8% eosinophilia. Examination of the stool on three occasions was negative for *E. histolytica*. A radiograph of the chest revealed a fairly massive infiltration at the right base and mid-zone.

A diagnosis of amoebiasis of the lung was made. Emetine and carbarsone were given, with marked improvement in the patient's general condition and great diminution in symptoms. A radiograph taken after two courses of emetine and carbarsone did not reveal any lung lesion.

Case III

This patient, a native labourer aged 38, when first seen had been treated for two months for pulmonary tuberculosis. He gave an indefinite history of abdominal pain about eighteen months previously, for which he had been treated in the out-patient department. He felt quite fit till about the last four or five months, when he began to complain of cough and sputum, blood-stained on occasion, and of progressive lassitude and disinclination for food.

On examination his general condition was poor and he looked ill. The temperature was 98 to 100.2°. There was dullness at the right base with poor air entry, and some moist rales were audible. The cardiovascular system was normal. Some tenderness was present in the right hypochondrium. The liver was not palpable. The sputum had an "anchovy-sauce" appearance; it was profuse and somewhat offensive, and was negative on direct smear and on concentration. Repeated blood counts showed a polymorph leucocytosis up to 12,000 per c.mm., but no eosinophilia. A radiograph revealed a fairly extensive lesion at the right base.

Following treatment with emetine and carbarsone, there was a very rapid and dramatic improvement and his cough and sputum disappeared. The lung lesion was not seen in a radiograph taken after one course of emetine and carbarsone.

Case IV

A native labourer aged 36 years first developed pain in the right side of his chest six months previous to admission. Cough ensued, with sputum which later became blood-stained. Early in 1939 he had had abdominal pain with frequent blood-stained stools, for which he was "treated" by a native witch-doctor.

On examination he was seen to be very thin. There were depigmented marks on the face, present from childhood, and slight clubbing of fingers. Breath sounds were absent over the right lower lobe in front, and crepitations were heard posteriorly. The sputum was T.B.-negative. There was tenderness over the liver, the edges of which were palpable.

On admission he was having a frank haemoptysis, but later produced "anchovy-sauce" sputum. A radiograph revealed an opacity at the right base. Amoebic abscess of the lung was diagnosed. No hiatus communicating with the liver detected by bronchography. Following emetine therapy the patient showed much improvement in general condition, and the lesion at the right base was not present on serial radiographs.

Case V

This patient, a male native, was a proved case of amoebic abscess of the right base. Bronchography was done in an attempt to outline the hiatus communicating between the liver and the lung. This, however, was unsuccessful. Following bronchography he was treated with emetine and carbarsone, the lesion then clearing completely.

Case VI

This patient, a native labourer aged 37, was admitted on May 7, 1940. For the last year or so he had had pain on the right side of his chest and cough associated with periodic attacks of shortness of breath. He described his sputum as "dark yellow" and blood-stained at times. He had had a frank haemoptysis about six months previously. He did not complain of night sweats, and his appetite was good. One sister has a "bad cough." He gave no history of amoebic dysentery, but was treated for roundworms in 1938, and had had an untreated urethral discharge in 1935.

On examination his general condition was fairly good; he was anaemic and afebrile, and there was clubbing of fingers. Signs of a large cavity were observed at the right base, and there was tenderness over the liver. Sputum was copious but not foul, brownish, and T.B.-negative. A radiograph revealed a cavity at the right base. Bronchography on May 10 showed the lipiodol filling up the bronchi surrounding the cavity, which was well outlined.

A tentative diagnosis of amoebic abscess with cavitation was made, and emetine and carbarsone were given. About three weeks later the cavity had completely disappeared, the cough and sputum had practically ceased, and there was great improvement in the patient's general condition.

Case VII

This patient, a native labourer aged 22, had been seen at a neighbouring hospital as a case of pulmonary tuberculosis. He gave a poor history, but so far as could be ascertained he began to cough about a month before admission. His sputum had been blood-stained on and off for about two weeks. He complained of progressive loss of weight and energy, loss of appetite, and night sweats. About six months before the coughing began he had had an attack of diarrhoea but could not remember whether he had passed any blood. The diarrhoea disappeared after he had taken one bottle of medicine. About two months earlier he had had some abdominal pain. He was admitted to hospital and a diagnosis of amoebic hepatitis was made, but he left at his own request after receiving only two emetine injections.

On readmission to hospital he looked ill and appeared to be somewhat dyspnoeic. The temperature was 98 to 102°. Clubbing of fingers and pallor of mucous membranes were present. There were dullness and crepitations at the lower half of the right chest, and a few moist rales at the left mid-zone. The cardiovascular system was normal. The liver edge was palpable two fingerbreadths below the costal margin, but was not tender. The sputum was negative on direct smear and on concentration. A radiograph showed infiltration at the right mid-zone and base

and some infiltration at the left mid-zone. Cyst forms of *E. histolytica* were found in the stool. There was a leucocytosis of 10,200 per c.mm., with a 7% eosinophilia.

He was given a course of emetine and carbarsone, and his temperature came down to normal after forty-eight hours. A radiograph taken ten days later showed the lesion on the left side to be cleared, and there was some clearing of the lesion on the right. The course of emetine and carbarsone was repeated, and another radiograph after one month revealed still further clearing of the lesion on the right. At this stage the white cells numbered 8,700, with a 5% eosinophilia. Stool examination was negative for *E. histolytica*.

This patient is feeling much better; his cough and sputum have greatly decreased, and he is anxious to leave hospital. At the time of writing he is still under treatment, but will be discharged as soon as the lesion at the right base has cleared.

Commentary

The diagnosis of pulmonary amoebiasis is important because of its very rapid response to a specific therapeutic agent—emetine. In the diagnosis various factors must be considered:

(a) *History*.—A history of blood and mucus in the stools, no matter how long before the lung symptoms are manifest, is an important point. However, many patients do not admit to any previous bowel disturbances.

(b) *Site of Lesion*.—In secondary pulmonary amoebiasis the lesion is inevitably at the right base.

(c) *Stool*.—Examination of the stool very often reveals the presence of cyst forms of *E. histolytica*.

(d) *Sputum*.—The macroscopic appearance of the "anchovy-sauce" sputum is characteristic. Microscopically the sputum reveals an absence of other bacilli, such as tubercle bacilli. In primary amoebiasis *E. histolytica* is said to occur in the sputum, but in our series of cases, in both the primary and the secondary forms, we have been unable to demonstrate the entamoeba.

Differential Diagnosis

Tuberculosis.—Involvement of the right base with the apices clear is against tuberculosis, except in primitive races, in whom basal tuberculosis is not uncommon. Repeated negative sputum examinations would rule out pulmonary tuberculosis.

Bronchiectasis.—Bronchography would demonstrate the presence of bronchiectatic dilatation at the site of the lesion.

Foreign Body in Bronchus.—Unless there is a clear history of aspiration of a foreign body or the foreign body is easily seen on the radiograph, bronchoscopy is indicated in order to make a diagnosis.

Neoplasms.—A neoplasm may cause bronchial obstruction with resultant atelectasis, which may simulate secondary amoebiasis in the radiograph. Bronchography may show a characteristic "rat-tailing" of the affected bronchus. Bronchoscopy would be of value in differentiating a malignant from an innocent tumour by obtaining a biopsy specimen.

Syphilis of Lung.—As is well known, the symptoms and signs of syphilis are protean in their manifestations. Particularly in the Bantu, syphilis may show itself in the lung as a large tumour or as an extensive infiltration. The presence of a positive Wassermann reaction and the rapid response to the arsenicals would confirm the diagnosis.

Unresolved Pneumonia.—This may show as an opacity on the radiograph. Serial radiographs would show a gradual disappearance of the lesion.

Avitaminosis.—Jersild (1939) reported a case of haemoptysis and lung infiltration caused by avitaminosis. In the

Bantu in South Africa, more particularly in the urbanized native, symptoms of avitaminosis are very frequent. We feel, therefore, that a condition of avitaminosis should be considered in a differential diagnosis.

Where the diagnosis of pulmonary amoebiasis cannot be definitely established we feel that in suspicious cases the patient should be given the benefit of a therapeutic test with emetine and carbarsone.

Summary and Conclusions

Pulmonary amoebiasis is discussed.

Seven cases of primary and secondary amoebiasis are described.

The importance of examination of the stool, sputum, and blood is emphasized.

Bronchography may be of value in demonstrating a communicating hiatus between the primary lesion in the liver and the secondary lesion at the right base.

All cases of pulmonary amoebiasis show a striking response to emetine and carbarsone.

We wish to thank Mr. M. E. Gibson, M.S.R., for taking the radiographs.

THE SURGICAL COMPLICATIONS OF AMOEbic DYSENTERY

BY

H. W. S. WRIGHT, M.S., F.R.C.S.
Surgeon, E.M.S.

The British Empire is at the moment fighting for its existence in a vast area where amoebic dysentery is endemic. So ubiquitous is this disease that about one-fifth of the whole population is involved. After the evacuation of Gallipoli in the last war 23.7% of 971 cases were infected. In China the percentage of carriers in over 13,000 cases was 20.3, and amoebic dysentery is the direct cause of between 5 and 10% of all hospital admissions. Since its effects may extend over a period of from three months to thirty years it is important, at this time, to emphasize that it has significance in every branch of clinical medicine, and will continue to have for many years to come.

It is necessary first to recall some of the pathological features of the primary lesion, which is an ulcerative inflammation of the colon. The *Entamoeba histolytica* gains access to the large bowel through being able not only to attack and ingest the mucosa but to secrete a ferment which causes coagulation necrosis and tissue lysis. Having reached the submucosa, it multiplies in the centre of a small nutritive cytolysed area, which in its turn, although surrounded by some oedema, is not shut off by an extensive tissue reaction. Spreading in this way, it causes thrombosis of veins and venules, invades the clot, gets into the portal circulation, and is from then onwards caught in the wide mesh of the liver substance. That this is usually a most effective filter is shown by two facts: (1) it was found impossible to produce anything more than cloudy swelling of the liver by injecting very large numbers of amoebae into the portal vein of kittens; (2) amoebae rarely get into the systemic circulation, although amoebic abscess of the brain and the epididymis is well known to occur very occasionally.

It is true that cases of infection of the urinary and even of the uveal tract have been described; but these have not been accepted as genuine by many critical workers. Nevertheless the fact that such records do exist should be a

stimulus to further clinical observation. In any case, further involvement usually takes place by direct spread to contiguous tissues, from either the liver or the bowel, and its clinical results may be conveniently described under one of two headings—*hepatic* or *colonic*.

Involvement of the Liver and its Effects

As previously stated, hepatitis is secondary to an ulceration of the colon. This is widespread in about half the cases, but it is important to add that a large proportion of hepatic complications occur in just those cases in which the caecum of an apparently healthy patient is the seat of one or more solitary ulcers. When the liver is invaded by amoebae it may become suddenly enlarged and inflamed to a surprising degree. This phenomenon, known as acute hepatitis, is often accompanied by an acute inflammatory reaction in the contiguous pleura or peritoneum, and consequently may produce effects which equal in drama and interest anything that occurs in clinical medicine. Moreover, nothing is so therapeutically satisfactory as an acute condition which is resolved by the administration of 2 to 3 grains of emetine hydrochloride.

In the ordinary course of events, when the case is elucidated the following features emerge: (1) There is a history of diarrhoea or amoebic dysentery, which may coexist or may have occurred a long time ago. (2) There are fever and pain: the former is variable and is, in contradistinction to that caused by the "ordinary" acute abdomen, apt to be spiky, high, and associated with sweating and chills; the latter is classically referred to the shoulder or, if the parietal peritoneum is involved, to the abdominal wall, causing rigidity and tenderness. (3) The liver is enlarged. (4) There is a characteristic leucocytosis of from 10,000 to 30,000, in which the polymorphonuclear cells seldom make up more than 75 to 80% of the total. If the leucocytosis is more than 80% the condition is probably not amoebic or there is an associated secondary infection.

Differential Diagnosis

These cases, often admitted as emergencies, are diagnosed by the clinician who is not "amoeba-conscious" as diaphragmatic pleurisy due to basal pneumonia, or appendicitis, or the perforation of a hollow viscus. Malaria with pneumonia, and acute cholecystitis, are not uncommon preliminary diagnoses, made before or on admission. It is fortunate in acute cholecystitis that the necessity for intervention is not urgent and that emetine does it no harm, for the differentiation may produce real difficulties. But the word "diarrhoea" somewhere in the history gives a clue to the diagnosis; the blood count provides strong circumstantial evidence; and the examination of a little blood-stained mucus from the stool makes it a certainty. Emetine provides a cure for the immediate symptoms. Below are two typical case histories:

Case 1.—A woman aged 50, when seen, was doubled up with acute abdominal pain. There was extreme tenderness and boardlike rigidity over the upper right side of the abdomen, which extended beyond the midline to the left, and on the right, down as far as the right iliac fossa. She had vomited at the onset about five hours previously; temperature was 103°, pulse 110. There were no physical signs of pleurisy or pneumonia, and no history of dysentery except that everyone in the East has a short attack of diarrhoea at some time or other. There was a vague history of indigestion, more suggestive of cholecystitis than anything else. No special diagnostic methods were available, so with some trepidation she was given an anaesthetic, and on palpation of a relaxed abdomen the liver was felt to be enlarged.

Case 2.—This patient, aged 43, was ordinarily a robust healthy woman. She was three months pregnant, and during an in-

fluenza epidemic complained of some malaise and a little pain in the back, with a temperature of 100°. Two years previously she had suffered a mild attack of acute amoebic dysentery, which was adequately treated and carefully controlled in the interval. Her stools after treatment were consistently negative, both for amoebae and for cysts. On examination her liver was painlessly enlarged down to just below the anterior superior spine. She had a leucocytosis of 23,000, of which 72% were polymorphs. This condition rapidly subsided with emetine therapy, and for the last fifteen years no further symptoms have appeared.

Between these two extremes come the cases which unfold themselves with textbook uniformity. In all of them, once the diagnosis is made, the treatment is simple. It consists in giving 1/2 grain of emetine deep subcutaneously or intramuscularly thrice daily for about three days, after which the dose is reduced to 1 grain daily. More than 15 grains should not be administered at any one time, and the patient should be in bed. After a few days' rest the standard routine treatment for amoebic dysentery, consisting of emetine bismuth iodide and quinoxyl, should be given.

If this acute stage is unnoticed the case may progress until massive colliquative necrosis of a large or small area in the liver has taken place and the patient gets a liver abscess. Its physical signs and symptoms are usually clear-cut. They are well known and adequately described. But in spite of this it has to be realized that almost every experienced physician in tropical practice has at some time or other seen at necropsy a large liver abscess which has been unrecognized during life.

Within the last few weeks a patient was admitted to the French Hospital in a state so serious as to preclude exact diagnosis or treatment. A few weeks previously a perinephritic abscess had been opened elsewhere. He died within twenty-four hours, and at necropsy his liver, which was of normal dimensions, was found to contain an abscess the size of a large orange in the right lobe posteriorly. Pleural and peritoneal reaction was minimal.

For the exact diagnosis and treatment of liver abscess paracentesis is necessary, and when proper precautions are taken this is a safe procedure. These precautions are: (1) the needle track through the parietes should be anaesthetized with novocain; (2) the needle should be of fairly wide bore and be marked at intervals of half an inch; (3) it should not be inserted more than 3½ in. for fear of entering the vena cava, and its direction should be upwards and inwards; (4) the shortest route to the abscess should be taken, and this is indicated by local bulging or radiological evidence of a change in the height of the diaphragm. Aspiration should be repeated until no more pus is obtained, and the pus should be cultured. Amoebae are seldom found in the first aspiration.

One important fact should always be borne in mind. A liver abscess is a cold abscess and should be treated as such. If culture shows it to be secondarily infected drainage is indicated, and in such cases it is imperative that the drainage track should be sealed in some way or other. The growth of a few small colonies of staphylococci, however, is not in itself an indication for radical surgical measures. Where emetine has no effect on the temperature chart it is a sure sign of secondary infection. If the patient has a pleural effusion and a liver abscess beneath the diaphragm the following line of treatment should be followed:

Both pleurisy and the liver abscess should be treated by aspiration. If the former becomes grossly infected from the lung, pleural drainage should be deferred, if possible, until the liver abscess has been aspirated several times and the patient is well under emetine treatment. If both are secondarily infected, then radical transpleural and/or transdiaphragmatic drainage should be done. In the few cases of this kind seen by me the pleural cavity has been well sealed off by adhesions.

Further extension of the disease beyond the liver is as a rule by direct spread. It is well known that the diaphragm and lung may be involved and that a pleural effusion may occur as with any inflammatory process below the diaphragm, but it is not so well known that from the liver it may spread to the skin, producing a large ulcerating surface. Such a case I was privileged to see in consultation. It was reported and illustrated by Heimburger (1925) so precisely that the account may profitably be consulted by anyone interested in the histopathology of amoebiasis. There was an area about the size of the palm of one's hand covered with pale oedematous granulations; its appearance was as if a quantity of red brickdust had been ground into the ulcerated surface. It healed rapidly with emetine therapy.

A liver abscess sometimes extends to the abdominal cavity. When this happens the size of the liver may be difficult to determine, and an inflammatory swelling arises which is, as a rule, somewhere continuous with the liver margin. This swelling may extend quite low down in the abdomen, limited either on the right or on the left by the falciform ligament. When it occurs on the left side it is very puzzling, because the occasional abscess arising in the left side of the liver is frequently overlooked. Such an abscess may extend well to the left above the spleen. In ordinary clinical practice it would be regarded as the result of a localized perforation of a peptic ulcer. Such localized intraperitoneal collections of pus from a liver abscess often have a somewhat indirect connexion with the liver, and it may be wise to open them and wash them out. If this course is taken, intentionally or inadvertently, the wound should always be sewn up without drainage and the parent liver abscess aspirated after localization. No harm comes if the patient is immediately put under emetine, and this should, if possible, be invariably done before any intervention is contemplated.

An extremely acute abscess may sometimes perforate into the peritoneal cavity, the case being admitted as an acute abdominal catastrophe. The condition is nearly always such as to preclude any surgical intervention.

Direct Spread from Colonic Lesions

Involvement of the muscular and peritoneal coats of the bowel wall is not uncommon. Sir Leonard Rogers has found amoebae in the lymph adherent to the base of an unperforated ulcer. Actual perforation is rare, but a localized slowly spreading peritonitis is by no means uncommon. It is important to bear in mind its possible existence, because it complicates the diagnosis of other abdominal conditions. The finding of amoebae in the stools makes the diagnosis simple.

Localized abscesses round the appendix are well known but not often seen, and the same may be said of retroperitoneal and perinephric abscesses. If their amoebic origin is not recognized extensive invasion of the abdominal wall may take place.

Ulcers of the colon may be secondarily infected and may produce a localized inflammatory mass which resembles diverticulitis. The lumen of the bowel may be so narrowed by oedema or fibrosis as to produce obstruction. In these cases routine treatment of the dysentery is not always sufficient, and a resection has to be performed.

Finally, the rectum is a common situation for amoebic lesions, and in severe untreated cases these involve the tissues in the ischio-rectal fossa, producing fistulae and ischio-rectal abscess. These may occur in patients who are extremely ill, originating in quite small ulcers without much surrounding infiltration. In more chronic cases the local ulceration may be widespread and, owing to second-

ary infection, the surrounding tissues be infiltrated widely. This may produce a particularly intractable form of stricture requiring colostomy for temporary relief.

Conclusion

It should be remembered that local lesions in the bowel do not as a rule progress thus far, but they do frequently and for a long time act as foci of irritation, exercising a profound influence on the physiology of bowel movement. Such patients have localized spasm and tenderness for years, their bowel is irritable, and they pass frequent stools containing a little mucus. They become bowel-conscious, and haunt the "colon lavatories" in the West End of London and the consulting-rooms of sympathetic physicians. They are diagnosed as cases of anything from spastic constipation to mucous colitis. They require above all things rest, both of the mind and of the colon.

This account by no means exhausts the widespread manifestations of amoebiasis, but enough has been said to show that a knowledge of its manifestations is necessary to every clinician handling cases in or from the East, and to suggest that to the use of the stethoscope must be added that of the microscope and sigmoidoscope as part of the routine examination of patients. By the employment of these methods we arrive at a positive diagnosis of a disease which can be "cured" in a sense that cannot often be used in the case of diseases commonly met with in this country.

CYSTICERCOSIS EPILEPSY

BY

CECIL W. EWING, L.R.C.P.&S.I. D.P.M.

Late Medical Superintendent, West Riding Mental Hospital, Storthes Hall

The case reported by Dr. W. Blyth (1941), to which he applied the above diagnosis, has many points of similarity to one which came under my notice some years ago, and in which a diffuse cysticercosis of the brain was found post mortem. Out of a large number of post-mortem examinations on mental hospital patients extending over a period of thirty-odd years this was the only case I met with. The condition, though rare, is of interest because—as pointed out by Sir W. P. MacArthur (1941)—of "the importance of considering it as a possible cause of epileptiform attacks commencing in a previously healthy adult after service or residence abroad." The histories of all the cases I found recorded come within this category, though one might extend the term "epileptiform attacks" to those presenting other ill-defined and vague symptoms of cerebral disease. The value of radiographic investigation in the diagnosis is emphasized by Dr. Blyth, but it is not clear from the particulars he gave that these investigations did reveal the presence of cysticerci in the brain tissue of his patient.

References in Literature

The case which came under my observation, and in which unfortunately the possibility of cestode infection as a cause did not occur to me, demonstrated from the necropsy that a condition of cysticercosis of the brain diffuse in distribution produces a clinical picture of epilepsy with dementia difficult to distinguish from the idiopathic form except by the more rapid development of the dementia and of a fatal termination. The cysts examined showed no evidence of calcification. I was so impressed by this massed invasion of the brain by these parasitic cysts that I consulted a number of standard textbooks on psychiatry and cerebral

pathology, but found only scanty reference to the condition, and in some instances none at all, and could discover less than half a dozen cases reported in medical journals in this country over a period of twenty-five years. From these sources I quote the following references:

Von Graefe, it seems, was the first to demonstrate the presence of cysticerci in the vitreous humour. Fagge mentions that as a bladder worm (cysticercus) the parasite is most frequently met with in the eye and in the brain; is often solitary or appears in small numbers, but that probably it is most frequently present in the muscles and subcutaneous tissues, where it is apt to escape notice. Da Costa states that in the brain the chief symptom is violent and increasing epilepsy. Bianchi mentions it in a footnote to his chapter on epilepsy. In *Twentieth Century Practice* (Collins, New York) there is an account of the condition in which it is stated that cysticerci in the brain are more common than echinococci; the symptoms are various—hysteria, hypochondriasis, acute mania, and various motor symptoms resembling Jacksonian epilepsy or cerebral tumour. Osler states that if the ripe ova of *Taenia solium* get into the stomach of man he is liable to become the intermediate host (the part usually played by the pig). This accident, Osler suggests, may occur in an individual the subject of *T. solium*, the most likely manner being by the forcing of mature proglottides into the stomach as by prolonged vomiting. The symptoms produced depend on the number of ova ingested and the localities reached: he groups them under general, cerebrospinal, and ocular.

In his own experience Osler met with only one instance—a patient who was admitted to his wards in a stiff and helpless condition, complaining of numbness and tingling in the extremities and general weakness, and who was first thought to have a peripheral neuritis. On examination subcutaneous nodules were found which proved to be cysticerci. There were none in his eyes, and he had no symptoms pointing to the brain. He saw another, with Friedländer in Berlin, with symptoms of diabetes and anomalous nervous disturbances. The post-mortem examination revealed a cysticercus beneath the valve of Vieussens and pressing on the floor of the fourth ventricle. As to the local distribution of cysticerci, he quotes 155 cases compiled by Stiles: the parasite in 117 was found in the brain, in 32 in the muscles, in 9 in the heart, in 3 in the lungs, subcutaneously in 5, and in the liver in 2. He adds that, except when in the eye, the diagnosis can rarely be made, or, when subcutaneous, one may be excised and examined. Purves-Stewart (1937) quotes a case (reported in the *Centralblatt für Neurologie*, 1902) of a characteristic form of vertigo produced by the presence of a cysticercus in the fourth ventricle. Beattie and Dickson (1925) state that the immature larval or cysticercus stage of *T. solium* may occur in man not only in muscle but in the skin and subcutaneous tissues, where they may be present in large numbers; and in various organs, especially the eye and the brain. In the brain the cysts may attain a considerable size. In the eye they have been known to persist for twenty years. Such infections originate (a) from the patient himself if harbouring the adult cestode, or (b) from a fresh infection from without. Those authors indicate the manner of its dissemination thus: after ingestion by a suitable intermediate host the embryonal shell is dissolved off and the active embryo proceeds to bore its way through the intestinal wall. By way of the lymphatics, or more probably by the mesenteric veins, it reaches the liver (which in the case of *T. echinococcus* forms the special habitat for its bladder-worm stage). In the case of *Cysticercus cellulosae* the embryo travels from the liver, probably by way of the blood stream, to muscles and other tissues of the host's body. In whatever situation the embryo is finally lodged it settles down and becomes passive, loses its hooklets, and undergoes distension with fluid, forming a cyst, and thus entering upon the larval, bladder-worm, or cysticercus stage of its development.

Stitt *et al.* (1938) state that, the segments or ova of *T. solium* having been ingested by the hog, the six-hooked embryo is liberated and becomes encysted chiefly in the tongue, neck, and shoulder muscles as an invaginated scolex ("measly pork"). They point out that the cysticercus of *T. saginata* (*C. bovis*) contains less fluid than *C. cellulosae*, and that, man having ingested the *C. bovis* in raw or imperfectly cooked beef, the adult stage of

T. saginata becomes established in his alimentary canal in about two months. In Abyssinia, they state, this type of cestode infection is said to be universal, and a man without a tapeworm (*T. saginata*) is considered to be a "freak." An important point is the fact that its larval stage scarcely ever appears in man, and it is therefore a much less dangerous parasite than *T. solium*, which readily establishes a larval existence in man if the ova are introduced into the human stomach. If the infection by *C. cellulosae* is not heavy, few symptoms may be observed. It, however, tends to invade the brain, next in frequency the eye, and so cause convulsions, blindness, or death. Instead of being the size of a pea these cysts, when forming in the brain, they add, "may be the size of a walnut or larger. *T. solium* infection is comparatively common in North Germany, but is exceedingly rare in England and the United States." Other references to the condition may be found in works on parasitology and in various Continental reviews and reports. Of actual cases reported in medical journals in this country the following were the only instances I could discover:

- (a) Multiple cysticerci of the brain and epilepsy (J. R. Gilmour, 1902).
- (b) Two cases of cysticercus cellulosae of brain (R. S. Black, 1903).
- (c) A case of cysticercus of brain (W. C. Sullivan, 1903).
- (d) Two cases of cysticercus of brain associated with epilepsy (G. E. Peachell, 1916).
- (e) A case of cysticercus of brain reported at the Bath Clinical Society (Waterhouse, 1911).

Record of a Case

The patient who came under my observation was admitted to the mental hospital certified as a person of unsound mind. He was a well-nourished man aged 31, an ex-soldier who had served in India. He had a history of three months' "behaviour disorder," having become so irritable and strange that he had lost his employment as a machine-man in a factory; he had become unmanageable at home and had threatened to shoot himself. He had no history of psychopathic heredity and none of venereal infection, and had previously enjoyed good health. Physical examination indicated an organic or toxic lesion of the central nervous system; he exhibited a degree of speech impairment with fine lingual tremors, exaggeration of deep reflexes, and Rombergism. Ocular movements were normal, the pupils equal but sluggish (fundi unfortunately not examined), and mental processes retarded, with a degree of confusion bordering on disorientation. He had fleeting visual and aural hallucinations and was unable to converse intelligibly. His habits were neglectful and unclean. The Wassermann reaction of blood and cerebrospinal fluid was negative, and the urine was negative for albumin and sugar. His condition suggested a tentative diagnosis of atypical G.P.I. Within twelve months he developed increasingly frequent epileptiform attacks indistinguishable from true epileptic fits; these were accompanied by a progressive degree of dementia till his death in a series of epileptiform attacks four years after admission to hospital.

P.M. Notes.—The brain unstripped weighed 48 oz.; there was an excess of C.S.F.; the pia arachnoid was congested and thickened, and decortication occurred on stripping it from areas over the cysts. Numerous small cysts were seen scattered over the cortex. They were encapsulated and semi-transparent, ovoid in shape, and varied in size from that of a pea to a little larger. They were mostly single, occasionally in groups of two or three. Their surface distribution appeared to bear a direct relation to the vascular supply, being most numerous in the area of the middle cerebral artery, and this may explain why the brain with its lavish vascular supply appears to be for the parasite a *locus minoris resistentiae*. Most of the cysts made cup-like depressions in the cortex; some were buried in it. They were also present in the sulci and fissures, but were absent on the base. On section of each hemisphere none were observed in the centrum ovale. In the lateral ventricles several of larger size were seen pushing up the ependyma of the floor and sides. In the basal ganglia cysts were present in the region of the lenticular and caudate nuclei and optic thalami. In the midbrain two were located in the right cerebral peduncle in the region of the substantia nigra and in the tegmentum, one below the red nucleus and two pressing into the aqueduct. None were found in the pons or medulla, and only two in the right cerebellar hemisphere.

The spinal cord was not examined. On a moderate computation there were upwards of a hundred cysts scattered throughout the brain. In other organs four were found in the left ventricle of the heart, in the myocardium; none in the liver or other glands. A dissection of the muscles was not undertaken except for those of the right thigh, where one cyst was seen embedded in fibres of the quadratus, which was the only muscle examined. No cestode was found in the alimentary canal. Few of the cysts showed any signs of calcification. On examination under low magnification the cysts had a defined fibrous capsule with some infiltration by small round cells and surrounded by a zone of increased neuroglial fibre growth with an increase of young glial cells. The neurones in close proximity were seen in varying states of degeneration, grading into normal cortex. The vascular elements were dilated, but there was no evidence of cellular infiltration of the perivascular sheaths. On section of some of the cysts the scolex and hooklets of the embryo were easily identified.

As the degree of calcification of the cysts is determined by time and other factors, it would be of interest to know if the radiographic films of the skull taken by Dr. Blyth revealed the presence of cysts in the cerebrum.

The few instances of this condition of cysticercosis I found reported in this country all occurred in ex-soldiers or in persons who had resided abroad. The cases recorded by Dr. Blyth and Sir W. P. MacArthur are opportune in illustrating the importance of considering the possibility of cestode infection as a cause of epileptiform attacks (and I would add all cases presenting anomalous signs of cerebral disturbance, from neoplasm to early atypical G.P.I.), particularly as at present so many of our countrymen are on active service in Africa and the East.

MASSIVE ADRENAL CARCINOMA WITH PSEUDO-HERMAPHRODITISM

BY

M. ALBERT, M.B., F.R.C.S.

Formerly Resident Surgical Officer, Loughborough General Hospital

Sex characters are primarily determined by the sex chromosome, but hormonal imbalance can alter the picture profoundly. A large group of cases is known in which changes in the adrenal glands can be demonstrated, presenting the "adreno-genital syndrome." In these cases the female sex characters regress, being replaced by those of the male. The changes are mainly dependent on the age of onset and the pathological character of the causative lesion.

A tentative classification may be made, following Broster and others (1932).

1. Clinical:
 - (a) Adrenal pseudo-hermaphroditism (before onset of female sex characters).
 - (b) Adrenal virilism (onset after puberty).
 - (c) Multiglandular syndrome (Cushing, Achard-Thiers, associated with anterior pituitary changes).
2. Pathological:
 - (A) Tumours: adenoma, adenocarcinoma, undifferentiated carcinoma.
 - (B) Simple hyperplasia (Vines's demonstration of the selective staining of the cortical cells by Ponceau's fuchsin (Broster and Vines, 1933).

The following is the record of an interesting example of Type A.

Case History

A female child aged 2 years 2 months was admitted to the Loughborough General Hospital, under the care of Mr. A. Goode, on September 12, 1940. The mother complained that the child had been fretful, and that its abdomen had been swelling during the past few weeks.

On examination the patient was seen to be a thin, puny, wasted infant. Cardiovascular and respiratory systems were normal. The breasts were minute; there was a growth of hair in the axillae and in the pubic region, of male distribution; the clitoris was enlarged, with a small glans, and the rudiments of prepuce were visible. An enormous ovoid smooth hard mass in the right side of the abdomen could be felt and pushed forward from the loin. The swelling bulged out the right flank; it extended vertically from the costal margin above to the false pelvis below, and medially beyond the umbilicus. It did not move on respiration, and was dull to percussion. The diagnosis was massive adrenal cortical tumour with pseudo-hermaphroditism. On account of its size it was decided that exploratory approach could only be made transperitoneally.

A laparotomy was done by Mr. Goode on September 13. Through a right paramedian incision a very large tumour of the right adrenal gland was seen perched on top of the right kidney, which appeared normal in size but was depressed down into the right iliac fossa. The growth was ovoid in shape, measured 9 in. vertically by 6 in. across, and its surface was covered by a very vascular capsule, fixed superiorly and posteriorly in the region of the portal fissure and inferior vena cava. There were several enlarged para-aortic glands, and the liver was also slightly enlarged. Removal of the main tumour was not attempted. An enlarged para-aortic gland was taken for section, and the abdomen was closed. The child's general condition rapidly deteriorated, and in spite of anti-shock measures she died next day.

Post-mortem Findings.—The vascular capsule over the tumour of the right adrenal gland was incomplete above, where the growth was attached to the diaphragm and inferior vena cava. Para-aortic glands and glands of the portal fissure were infiltrated. The growth itself was of a greasy yellow appearance, was friable, and had large areas of haemorrhagic necrosis. The left adrenal and both kidneys appeared normal. There were no obvious secondaries in liver or lungs. The uterus was very small and the ovaries were represented by two tiny fibrotic nodules.

A portion of the growth was sent for examination, and Prof. G. Haswell Wilson reported as follows: "A cellular malignant tumour with the characters of a carcinoma of the suprarenal cortex. Details are more distinct in the gland specimen, as the tumour itself is the site of extensive necrosis."

Discussion

The formulae of testosterone and corticosterone, the typical substances of the male and cortical hormones respectively as given by Gaddum (1940) are:

and their similarity is apparent. Also to be noted is their close chemical relation to those other sterones oestradiol and progesterone. Clark (1940) states that corticosterone can indeed be synthesized from testosterone.

A further point of interest arises from Broster's (1941) report of a case of "feminism" in the male; this showed

hypertrophy of the adrenals, a positive Ponceau-fuchsin reaction, and clinical improvement following unilateral adrenalectomy. Sterone excretion was reduced following operation.

Perhaps these intersexual changes may be diagrammatized like this :

♂ + excessive or altered sterone → virilism
 ♀ + excessive or altered sterone → feminism

thus providing a further example of the bisexual properties of the sex hormones when acting on the different biological soils determined by the sex chromosomes.

My thanks are due to Mr. A. F. Goode, honorary surgeon, Loughborough General Hospital, for permission to publish this case, and to Prof. G. Haswell Wilson, University of Birmingham, for the pathological report.

Medical Memoranda

Local Chemotherapy as a Curative Measure

The prophylactic value of the sulphonamide group of drugs when applied locally in potentially infected wounds is amply witnessed by the numerous accounts published. My experience in this direction has been small, but I have used local chemotherapy from a curative point of view in wounds already infected.

I first used sulphanilamide locally in two cases of tuberculous infection. One patient, a girl aged 14, exhibited a tuberculous osteitis of the third left metatarsal and a cold abscess on the ulnar border of the right hand. Both these lesions eventually gave rise to ulcers which defied treatment until a paste similar to bipp, but with sulphanilamide 5% in place of bismuth, was tried. The ulcer on the hand cleared up in about fourteen days, but that on the foot, although it became much smaller and cleaner, refused to heal completely, presumably because of the underlying osteitis. The second case was one of tuberculous adenitis, with cold abscess formation. This was opened, curetted, swabbed with 6% iodine, and sewn up. This procedure had proved successful in previous cases, but this one became secondarily infected and broke down. Fomentations were applied, and a surrounding crop of pustular eruptions developed. The whole area was treated with the sulphanilamide-iodoform paste, and it healed completely in seven days.

Following these two cases local chemotherapy was tried on a radical mastectomy wound that had become infected and had broken down, leaving a large suppurating area. The first application was a suspension of sulphanilamide 5% in 1 in 1,000 flavine, but it made very little impression on the infection. Since the predominating organism was a staphylococcus a paste of uleron 5%, with equal parts of zinc oxide and paraffin, was used. This cleaned up the wound sufficiently for a Thiersch graft to be made to close the defect.

A similar paste, with sulphanilamide in place of uleron, has been used on a large number of cases, of which the following are examples:

Case 1.—Infected burn over right eyebrow caused by molten aluminium. This had been treated by various applications for ten to twelve weeks without improvement. Daily dressings with the paste cleared it up in seven days.

Case 2.—A woman presented herself with a peculiar black eschar just above the right knee. This looked like a burn treated with tannic acid, but no history could be elicited. Fomentations were applied, and the eschar separated in fourteen days, leaving an ulcer resembling a syphilitic lesion. The Wassermann reaction was negative. The paste completely cleared up the area in seven days.

Case 3.—A case of osteomyelitis which had been operated upon had been in the wards for some time. The upper part of the wound had healed, but the lower part remained open and freely discharged. The paste cleaned it up, leaving healthy granulation tissue.

Several common lesions and small infected wounds have been successfully treated with the paste, and my colleagues at the hospital have used it on several occasions with equally satisfying results. Herpes vulgaris and impetigo seem to respond particularly well.

Following these cases an emulsion of sulphanilamide 5% in cod-liver oil was made up. This has been used as a routine dressing in the casualty department for the past three months, and no case of infection of primary suture of a wound has occurred. In addition, it is most useful where the cosmetic result is of importance. All wounds or incisions of the face and hands are sutured with gossamer silk and dressed daily with the emulsion. Sutures are removed in four to five days, and the wounds heal with only very faint scars. As a curative application the emulsion has surpassed the paste. An infected finger with necrosis of the phalanges was amputated at the metacarpophalangeal joint. The wound was dressed with glycerin and flavine, and when seen a week later it had broken down in three places, was discharging pus, and showed the sloughing end of an extensor tendon. The slough was removed and the wound treated with eusol dressings for five days. It was then clean, but the three sinuses were as large as ever. Sulphanilamide emulsion was used for the daily dressing, and the wound healed completely in ten days.

Several similar cases of grossly infected wounds have been treated with success. The following facts have emerged: (1) If there is free discharge of pus from the wound the emulsion or the paste is not very effective. If, however, the wound is treated with eusol dressings for a few days and then with the emulsion healing is rapid and permanent. (2) Resistant cases should be submitted to bacteriological examination, and the sulphonamide chosen to suit the infecting organism. (3) Many patients with infected burns have presented themselves. A large number had been treated elsewhere with tannic acid, and had arrived with the tan bathed in pus. In all such cases the burn was cleaned up, the coagulum removed, by eusol dressings if necessary, the surrounding skin painted with 1% gentian violet, and the emulsion applied daily. Healing takes place usually in ten to fourteen days. In no case have toxic symptoms appeared, although in several cases very large areas have been treated. It seems possible that the nature of the preparations used may be responsible for the absence of such manifestations.

The following preparations are in daily use at the hospital:

R Sulphanilamide powder 5%
 Zinc oxid. } aa partes aeq.
 Paraffin. liq. (sterile) }

Fiat pasta.

R Sulphanilamide powder 5%
 Iodoform } aa partes aeq.
 Paraffin. liq. (sterile) }

Fiat pasta.

(This is used chiefly for tuberculosis lesions, though it has been employed instead of bipp in a few cases of osteomyelitis.)

R Sulphanilamide powder gr. 175
 Ol. morrhuae fl. oz. 4
 Acid. oleic. m 36
 Aq. calcis ad fl. oz. 8

Fiat emulsione.

I am indebted to the pharmacists of the hospital for their willing co-operation in making up the various preparations. I also wish to express my gratitude to Mr. J. Elgood, honorary surgeon to the hospital, for permission to publish these cases.

R. VERNON JONES, M.B., B.S.,
 House-surgeon, Royal Gwent Hospital.
 Newport, Mon.

Dr. Norman Manson has been appointed warden in succession to Lieut.-Colonel Sir John Strathearn of the St. John Ophthalmic Hospital, Jerusalem, who has resigned owing to ill-health after holding the office of warden for twenty-two years.

Reviews

CANCER OF THE RECTUM

Carcinoma of the Rectum, with Special Reference to its Pathology and Treatment: Based on a Survey of Cases at St. Mark's Hospital during the Past Ten Years. By Lionel E. C. Norbury, C.B.E., M.B., B.S., F.R.C.S. (Pp. 66; illustrated. 7s. 6d.) London: H. K. Lewis and Co., Ltd. 1941.

Many will be grateful to Mr. Lionel Norbury for publishing his Hunterian Lecture on carcinoma of the rectum, because it was delivered in January of this year, when owing to war conditions many who would have liked to be present were not able to attend. Summarizing, as it does, present views on pathology and treatment held at St. Mark's and recording the author's experiences over the past ten years, this is a valuable and authoritative statement of what modern surgery has to offer for rectal cancer. Also included are the present views on pathology and method of spread of the disease, and something of diagnosis, management, and the history of various methods of surgical attack. Dealing with only adenocarcinoma or columnar-celled carcinoma, and excluding squamous cancer of the anal canal, Mr. Norbury finds that the disease is twice as common in men as in women, that the upper or recto-sigmoidal region is affected more often than the ampulla, and that the average age when surgical treatment is undertaken is 57. As a rule mucoid or colloid tumours are highly malignant.

In regard to treatment of rectal carcinoma, the author on the whole favours the radical one-stage perineo-abdominal excision with the patient in the Trendelenburg lithotomy position and with two surgeons working simultaneously, as has been practised by Devine in Melbourne and Kirschner in Germany. The perineo-abdominal operation appears to be as radical as the more widely practised abdomino-perineal operation and to produce less shock. He believes that conservative resection is occasionally justifiable and that operations such as those of Hartmann and Grey Turner have their place in treatment, but his general conclusion is that such operations are not often desirable, and he concludes with Ernest Miles that "there is no place for conservatism in the surgery of malignant disease." We would add, however, that in an early and high lesion there is occasionally a strong case for conservatism as the sphincters are thus preserved; particularly is this so since studies of the pathology, here referred to, have shown that downward spreading does not occur until there is a general choking of the spread in an upward direction—that is, until the lesion is rather advanced.

This little book is well illustrated with photographs, diagrams, and tables, and its great value consists in the fact that it is both authoritative and recent.

"THE RELATIVITY OF REALITY"

The Relativity of Reality. Reflections on the Limitations of Thought and the Genesis of the Need of Causality. By René Laforque, M.D. Translated by Anne Jourd. *Nervous and Mental Disease Monographs*, No. 66. (Pp. 92. 52.50.) New York: Nervous and Mental Disease Publishing Company. 1940.

It is curious how often what looks like a discovery turns out to be only a re-formulation in new language of an ancient fact of observation. In this book René Laforque postulates a "super-ego of the species," or a kind of conscience which is inborn and inherited in contrast to the acquired super-ego of parental introjection. What is this but the still small voice of God in new terminology? The main theme of the book, however, is that the scientific stage of intellectual development depends upon attainment of the genital stage

of libido development. The "anal stage" is associated in psycho-analytic theory with projection and psychological animism, whereas the "genital stage" is concerned with relationships between people and objects generally, which is the essential stuff of scientific preoccupation. He describes accordingly an anal and a genital type of intellect, the former limited by failure to make contact with reality, so that it is very prone to develop anxiety; if reality forces itself upon it, magic is called in to redress the situation, and an overbearing attitude designed to reassure its owner is adopted. Hence the intellectual attitude of the anal stage is authoritarian and intolerant. Such people only argue: they cannot discuss. They are described as overbearing, vain, proud, conceited, and opinionated, and, unlike the people of genital attainment, are not co-operative. The genital ego, having overcome its fear of castration, no longer requires magic defences, and by appearing less strong is really stronger, since it is entirely its own master.

These formulations depend largely on a customary mode of psycho-analytic reasoning, which makes analogy very conclusive of identity. For example, the desire to know the why and the wherefore of things which is characteristic of the scientific attitude is considered to be the direct descendant of the earlier anxiety about relationships between the parents. These are all psycho-analytic ways of saying that intellectual maturity depends on libidinal maturity. In so far as the individual has fallen short of genital maturity he is held to be incapable of truly scientific thought, though he may be an intellectual concerned with thought processes and abstractions. But what in the light of these views—which are spun ingeniously for us without case records to support them, and which remain, therefore, airy conceptions founded on analogies—shall be said of the author's own inclinations for a scientific mode of thought?

PHOTOGRAPHY THE SERVANT OF SCIENCE

The Scientific Photographer. By A. S. C. Lawrence, Ph.D. (Pp. 180; 83 illustrations. 15s. net.) Cambridge: University Press. 1941.

The title of this excellent manual might lead one to suppose that it describes a special scientific photography for scientists. But it does nothing of the kind, and there is no such photography. The possibilities and limitations of photography are the same for the scientific worker as they are for the serious amateur. The camera itself is a scientific instrument, whether in the hands of a laboratory technician or a seaside snapshotter, and, as the author says, it demands respect "and sometimes intelligence." This is a treatise on photography as a serious pursuit, an engrossing one in itself, which demands for the purposes of scientific record a knowledge of the theory and an understanding technique.

Dr. Lawrence begins where most of the elementary textbooks on photography leave off. He gives none of the instructions which may be purchased with photographic materials (except that he does include an appendix of useful formulae for solutions), but he discusses the underlying chemistry, the formation of the lens image, the mechanism of the camera, the rules of composition and perspective, and the processes of developing and printing. He adds a chapter on colour photography which gives in a dozen pages as succinct an account of that subject as any ordinary reader would desire. Finally he mentions a number of scientific applications, including the value to medicine of infra-red photography and photomicrography. He insists that photography is inadequately appreciated in the laboratory to-day, that full use is not made of it, that it is left to an amateur whose enthusiasm can be exploited when necessary; but when he goes on to say that no organized attempt has been made to use cinematography either for

research or for serious teaching, the recollection of many educational films we have seen flickers back again in silent reproach. The book is beautifully produced, as it deserves to be at the price, and the illustrations are none of them just thrown in to shew what photography can do, but are necessary to elucidate the text.

Notes on Books

A pamphlet entitled *Discussion Groups for Citizens*, by Mrs. E. M. HUBBACK, has been issued by the Association for Education in Citizenship, 19, Wellgarth Road, London, N.W.11, price 7d. post free. An important quality required by citizens in a democratic community is that of good judgment, based on clear thinking, tolerance of the views of others, and a background of knowledge. One of the best means for encouraging such qualities is the discussion group, which makes a far greater call on the activities of its members than does passive listening to lectures or talks. This pamphlet describes briefly various forms of discussion groups; especially those which aim at bringing in the shy and inexperienced member, thus avoiding the weakness of so many groups where the talking is confined to two or three vociferous individuals. There are also short sections on practical activities which lend themselves to training for citizenship, such as drama—the producing of plays related to contemporary or historical affairs—mock trials, model parliament, social surveys, the uses of films. Nothing is suggested which has not been found to work well in practice. A valuable feature is a book list, on contemporary affairs, graded according to price, each section setting out pamphlets, Penguins, and other books under half a crown, which may be bought by all members of a group, and others over half a crown for consultation by leaders or speakers.

Mr. CHARLES KEOGH, F.R.C.S., has written a small pamphlet entitled *First Aid for Fighting Men* (Sifton, Praed and Co., Ltd.). The pamphlet is printed on four sides of stiff paper, which folds into a convenient shape for carrying in the pocket. The essential first-aid methods which can be applied by "the fighting man" are described in the briefest and simplest fashion under twenty numbered paragraphs. Each paragraph is introduced by a striking phrase printed in bold type, so that the first-aid can immediately find out what he wants to know without any trouble. The possession of this pamphlet by the men in the Forces would, we believe, save many disasters that otherwise would occur. We are informed that neither the publishers nor the author intend to make profit from the sale of the pamphlet, which is priced at 6d. for single copies.

Preparations and Appliances

AN IMPROVED METHOD OF OBTAINING BACTERIOLOGICAL SPECIMENS FROM WOUNDS TREATED BY THE CLOSED- PLASTER METHOD

Dr. H. L. DE WAAL (Bacteriology Department, University of Edinburgh) writes:

In an article in this *Journal* (1941, 1, 877) Orr-Ewing, Scott, and Gardner described an apparatus that allowed of access to such wounds. It consists of a "perspex" cylinder with a piston, and is incorporated in the plaster immediately above the wound. Specimens are taken by withdrawing the piston and collecting material from the exposed wound surface. A method similar in principle was used in our earlier investigations.

The main disadvantages in the use of such an apparatus are: (1) the inability to obtain a true representative specimen of the wound flora; (2) the danger of admitting extraneous bacteria to the wound; (3) the tendency for oedema to occur in that part of the wound directly beneath the cylinder base, and at a

later date the formation of granulation tissue into the cylinder base, which tends to interfere with the flow of pus from other parts of the wound into the field of observation; (4), and perhaps most important of all, the fact that the wound surface at the base of the cylinder is aerobic or partly aerobic, whereas under plasters without windows the conditions may be totally different: it may be understood why the bacterial flora of the wound at the base of the cylinder differs but little from that of wounds treated without plaster. The following method has been devised to eliminate these disadvantages so far as is possible.

After the wound has been cleaned, sterile thick absorbent thread is laid backwards and forwards across its surface, starting at the centre and passing to the periphery. The free end of the thread lies away from the wound. The whole of the wound surface is now covered with sterile vaselined gauze. The free end of the thread is passed through a "one-piece" vulcanite cylinder with a flat base and with the sharp edges smoothed

off. (The vulcanite should be of good quality and able to resist autoclaving.) A groove is cut in the flat base of the cylinder, in which the thread lies. This allows for the subsequent easy withdrawal of the thread. A sterile rubber bung is inserted into the upper opening of the cylinder. While the plaster is being applied an assistant steadies the cylinder at the edge of the vaselined gauze (about 1.5 cm. from the wound margin). In taking specimens the procedure adopted is as follows:

The rubber bung is first removed, and with a swab slightly moistened in antiseptic the inside of the cylinder is cleaned and then dried with another swab. That portion of thread which had been within the cylinder and had come in contact with the antiseptic is now withdrawn, cut off, and discarded. A further piece of the thread is pulled out (about 1.5 cm.), snipped off, and placed in a sterile test tube. This portion of the thread has been exposed to air, and should be examined as a control. The next few centimetres are similarly collected, and give a representative sample of the wound flora.

Depending on the length of the thread originally laid on the wound, five or more specimens may be taken at varying intervals. The last portion of the thread comes from the centre of the wound, the part likely to heal last. After each specimen is taken a fresh sterile rubber bung is inserted in the mouth of the cylinder.

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY AUGUST 23 1941

THE FUTURE OF MENTAL HEALTH

The future of medicine is a topical subject for debate at the present time, and the main headings under which it falls are the rearrangement of hospital services, the greater emphasis on preventive as opposed to curative medicine, and the more comprehensive and better-directed training of the medical practitioner. All three of these are dealt with in the report of the Mental Health Committee of the British Medical Association recently published in pamphlet form and summarized in the *Journal* to-day at page 276. The information and suggestions contained in it will unquestionably be of service to the Medical Planning Commission in its deliberations. Perhaps the most important conception that has been brought into prominence since the war is the regionalization of hospitals. The model scheme for the treatment of mental illness set out by the committee should lend itself admirably to the regional idea, for clearly the centres on which outlying clinics are based must not be too big, and they should be made to serve a well-organized area. For purposes of propaganda and education, for instructing the public and therefore avoiding much that is preventable in the field of mental illness, local organization will have obvious advantages, and thus "preventive" work is perhaps the most important task which must be undertaken by "mental medicine."

As with physical diseases the results of treatment of mental illness are not so satisfactory as any of us could wish, nor so brilliant as the enthusiasts would have us believe. This is well brought out in the report, but so also is the very large number of persons who require some sort of psychotherapeutic treatment, and both these considerations emphasize the need for prevention or at least for catching the patient young. An enormous amount of research and intelligent correlation of results is necessary in order to give us more knowledge and therefore better understanding of the nature and cause of mental illness; but here also a certain amount of decentralization, as is contemplated in the regional idea, will be beneficial, for too large accumulations of records simply become unwieldy and impossible of employment to advantage. The role of the voluntary organizations will continue to be an important one, for medicine alone cannot provide for mental health or indeed for any sort of health. Education and the social services are essential partners, and it is in assuring smooth co-operation between these three agencies that the voluntary organizations have their place. The committee responsible for the B.M.A. report is content to endorse the findings of the Feversham Committee, whose report on these voluntary organizations covered the ground very adequately, but it does insist on the proper education, qualification, and organization of the ancillary services which are so necessary in the general scheme.

Perhaps the most important problem of all is the provision of enough medical practitioners trained in mental medicine to deal with the large numbers of patients, both young and old, who require care and treatment, whether to restore them to full health, to ameliorate their inevitable invalidism, or to prevent them from doing harm to themselves or others. The report lays sufficient stress on the need for this, but also dwells on the difficulties that still beset its achievement. The treatment of mental illness is a long and complex matter demanding a wide knowledge of general medicine and very specialized skill in a particular field of therapy. But it seems that success in this treatment depends not only on knowledge which can be more or less readily acquired by anyone, but on a special type of personality of the doctor who practises this branch of medicine. Can such persons be picked out at the appropriate stage of their medical careers so that time and energy are not wasted in trying to train unsuitable persons? Having chosen the right person to train, is it a matter of general agreement how he should be trained and which of the many existing schools of psychotherapy he should be encouraged to espouse? When he has undergone a long and arduous course are there enough posts, full-time or, better, part-time, the emoluments of which will keep the wolf from his door while he builds up a practice in a branch of medicine still looked upon with a good deal of suspicion and prejudice? Unfortunately none of these questions can be answered now with a categorical affirmative.

In fine, the Mental Health Committee has collected and clearly set out much useful information, but in so doing it has perhaps emphasized the uncertainties and incompleteness of the subject of its reference rather than formulated any final conclusions. Nevertheless there can be no question that interest in, understanding of, and care for the mental patient have moved forward at a great pace since the beginning of the present century, and if this report is no final word on the subject it allows us to entertain not only a hope but a confident expectation that the difficulties that confront us to-day will eventually and before too long be surmounted. It is a commonplace that the last war gave a tremendous impetus to advance all along the medical front, and perhaps especially on the mental front. No one should doubt that after this war an even greater stride forward will be achieved; and perhaps, as a result of that progress, there will be no more war.

THE SOYA BEAN

We have it on the authority of the *Times* that after the Polish campaign Nazi official circles were boasting in Berlin that without soya food preparations it would not have been possible for the German Army to advance as quickly as it did. The Germans are undoubtedly making great use of the soya bean, and scientific articles published shortly before the outbreak of the war show clearly the important part it was expected to play in the food economy of the Reich as a source of protein and fat. Before being impressed into the service of total war, the soya bean had a long and honourable history

as one of the main foods of Oriental mankind for more than a hundred generations. It might be instructive to consider the nutritional background of its long-established eminence in Asia, its recent rise on the American continent, and its latest emergence in Europe in the service of Mars.

Glycine hispida, or *Soja max*, to give it its latest name, is a leguminous plant closely related to peas and beans. There are several hundred cultivated varieties, and the composition differs greatly according to the variety and to the conditions of growth. The outstanding nutritional characteristics of the bean are a very high protein and fat content, a large amount of mineral matter, and the almost complete absence of starch. In the Orient its chief uses are as a source of edible fat, as soya bean milk—a fine, stable emulsion of the bean constituents in water—as various cheese-like preparations, and in the form of sauce as a universal condiment. Most of these preparations are unlikely to appeal to the taste of the average European. The bean, as such, does not lend itself readily to cooking, which not only has to be very prolonged to give the necessary softness but in the absence of starch does not yield as satisfactory a product as peas and beans. A most valuable foodstuff can, however, be produced by subjecting the beans to some form of heat treatment, removing the hulls, and grinding the beans to a flour. If untreated the flour quickly becomes rancid, and, moreover, has an unpleasant “beany” taste. Many patents have been taken out for the preliminary treatment. They are largely modifications of the original procedure of Berczeller, in which the beans are treated with saturated steam for 10 to 15 minutes. Such flour has a sweet, pleasant, nut-like taste and may be kept at room temperature for months and even years without spoiling. It is in this basic form that the soya bean is being used in Germany and would doubtless be useful here. A consideration of the composition of the flour rather than of the whole bean is therefore indicated, but the flour has essentially the same composition as hull-free soya beans themselves.

The soya bean, and hence the flour, is outstandingly rich in protein, of which the latter contains some 40%. The protein is of good quality, at least equal to that of whole wheat and superior to the proteins of white flour and to those present in peas and ordinary beans. It is also easily digestible. It is generally agreed that the digestibility and biological value of the protein are improved by cooking. The content of fat, of which soya bean flour has some 20%—that is, much more than ordinary peas and beans, though less than peanuts—is also remarkable for this class of food. In consequence the calorific value of soya bean flour is high—about 470 calories per 100 grammes, as compared with 370 for white flour. The ash is exceptionally high, about 4.7%, or nearly ten times as much as in white flour and almost double that present in whole wheat, peas, and beans. Soya bean flour contains some 1.6% potassium, 0.14% sodium, 0.23% magnesium, and as much as 0.2% calcium (or ten times as much as in white flour). This large proportion of fixed base renders the ash strongly alkaline. The phosphorus amounts to some 0.6%; a large part of it is present as phytin phosphorus, and this may affect the availability of the soya

bean calcium. The iron content is variable but high, from 6.7 to 30 mg. per 100 grammes. This can be compared with 1 mg. present in white flour and 3 mg. in wholemeal flour. Edible flours can also be obtained from the meal left after the removal of the soya bean oil. A press-cake flour still contains some 7% of fat, and the ash and protein contents are naturally higher than in high-fat flours. A product exceedingly high in protein is obtained by solvent extraction, but it is low in mineral matter, and such flour is of inferior value in human nutrition.

β -carotene is present in the soya bean, and a recent study showed fluctuations according to variety from 18 to 243 μ g. per 100 grammes of air-dried beans. As by definition 0.6 μ g. of β -carotene is the equivalent of one international unit of vitamin A, these amounts correspond on paper to 30 to 400 i.u. per 100 grammes; but it must be remembered that carotene is doubtless a less effective source of vitamin A activity for the human being than the preformed vitamin. In any case the carotene content of the soya bean is not very high when compared with green vegetables and carrots. The soya bean flour probably contains less. Moreover, in considering its value as a potential source of vitamin A, it is well to remember the curious observation of American workers that when fed to cows fresh or heated soya beans have a depressing effect on the transfer of vitamin A to milk. There is no vitamin D in the soya bean or flour, neither do they contain vitamin C. Vitamin B₁, however, is present in relatively large quantities, a recent reliable estimate giving nearly 5 i.u. per gramme of dry bean. This is more than that found in whole wheat (0.6 to 3.3 i.u.) and more than ten times the amount (0.3 i.u.) present in an average white flour. There is reason to believe that there is no serious loss of vitamin B₁ in the manufacture of the flour. The riboflavin content is also appreciable—1.6 μ g. per gramme: that is, of the same order as in milk.

In the United States and on the Continent soya bean flour has been successfully used as an addition to wheat and rye flour in making bread, biscuits, cakes and pastries, macaroni and the like, as a constituent of soups and various prepared foods, and as a filling for sausages. The valuable nutritive properties of the bean could undoubtedly be put to good use in this country. Included in “blitz soups,” provided in communal feeding centres, it would contribute its useful quota of fat, protein, and minerals, and form a desirable addition to our wartime dietaries. There is every reason for a serious consideration by responsible quarters of the importation on a substantial scale of this compact foodstuff.

TRAUMATIC LESIONS OF THE HEART

But little attention has been paid to the possibility of injury to the heart after non-penetrating trauma to the chest. Evidence of such injury is especially apt to be missed if there is a long latent period between the injury and the appearance of cardiac signs and symptoms. The chest wall is elastic, particularly in the young, so that when it is compressed the heart is squeezed and in severe cases ruptured. Short of this, pericardial and local myocardial lesions of

various kinds have been described. Rupture of a cusp of the normal aortic valve as the result of extreme muscular effort must also be included under the heading of traumatic cardiac lesions, although here the trauma is indirect: such an event is rare, but there is no doubt that it occurs. E. Warburg, who reviewed 202 cases of traumatic injury in a special monograph,¹ has recently² added a further fifty-nine. Pericarditis, either dry or with serous or haemorrhagic effusion, was a not uncommon sequel to injury. When lung tissue and the pericardium are torn air may enter the latter, and fluid in the sac may then produce a splashing sound as in hydropneumothorax. Traumatic pericarditis usually requires no local treatment unless infection occurs; the prognosis is good. Various disturbances of cardiac rhythm have been noted after trauma, especially auricular fibrillation, which Warburg found in one-fifth of all cases. Heart-block occasionally happens and, if discovered in a young subject, may be wrongly diagnosed as congenital. A few cases of angina pectoris, including infarction angina, have been recorded—mostly in older subjects (probably with atheromatous coronary arteries), but also, rarely, in the young. Partial rupture of the ventricular wall may be followed by aneurysm and complete rupture, this complication being most likely to arise about two weeks after the initial injury, as in myocardial infarction. In any case in which such an injury is possible absolute rest is essential. Changes in the electrocardiogram may confirm the diagnosis of traumatic cardiac lesions, as illustrated by a case reported by R. G. Anderson.³ A man of 30 was trampled on by a horse and suffered shock and pain in the chest. R—ST and T changes in electrocardiograms indicated focal myocardial injury; they developed over a period of one year in a manner comparable to the changes of cardiac infarction. Special attention to the heart in cases of recent injury to the chest, and inquiry as to trauma in the history of heart lesions of doubtful aetiology, may show that traumatic lesions of the type described are less rare than has been supposed.

HOME CARE FOR RHEUMATIC CHILDREN

It is now accepted by public health authorities in this country that children with rheumatic heart disease need prolonged convalescence in special "heart homes" if this can be arranged. Unfortunately there are not, even in peacetime, nearly enough of these homes, and there are certain disadvantages in keeping children in institutions for periods running into months. Recent reports from Boston⁴ on this problem, solved there with apparent success by supervised convalescence in foster-homes or in the child's own home, will therefore be received with interest by those who are concerned with the care of rheumatic children in this country. Dr. Paul D. White, in an introductory article, describes how the method was evolved out of the work of the Children's Cardiac Clinic of the Massachusetts General Hospital. Various other bodies co-operated, and from 1934 to 1939 a special study was made of a group of sixty-four children between the ages of 5 and 15 years who had been recommended for convalescent care from the wards or clinics of the Massachusetts Hospital. Whether home or foster-home care was preferable depended upon the home conditions and the severity of the disease. Dr. E. F. Bland explains that many factors, some only remotely related to the patient's illness, had to be taken into account

when deciding where the child was to convalesce. Throughout the study the tendency was to advocate bed-care at home when it seemed at all feasible. Foster-home facilities were reserved for those children needing more expert supervision and nursing care than they could have received in their own homes. Medical-social workers have kept in constant touch with each patient; all the children were visited at monthly intervals by the physician in charge, and in special cases more often. The assistance of community-health nurses was invaluable in following the progress of patients more seriously ill. After the project was started it became evident that for the intelligent management of the patient certain minimal laboratory guides (such as the sedimentation rate) were necessary, and arrangements were made for a part-time technician to perform the tests, if necessary in the children's own homes. Miss Edith M. Terry outlines the various medical-social methods employed and the resources available for the children. These include educational aids by home teaching, tutoring by college students, recreational facilities provided through an ingenious "In-Bed Club," and occupational therapy. Further details of the social workers' essential part in the scheme are supplied by Miss Virginia B. Ebert, who points out how essential it is to get a clear idea of the environmental influences in the patient's illness, so that parents and patients may be properly guided and enabled to make the necessary adjustments. The results noted are compared with those obtained from a large group of children who spent their convalescent period in a special home—the House of the Good Samaritan, Boston. It was clear, after allowance had been made for a high proportion of seriously ill children in the institution group, that over the five-year period there was very little difference in the proportion who developed heart disease. The cost of convalescence in foster-homes was, however, a little over half the cost in the special home, and only about a quarter of the daily cost of keeping a child in bed at the Massachusetts General Hospital. It is also pointed out that home or foster-home convalescence probably offers less exposure to respiratory infections; thus there are likely to be fewer recrudescences of rheumatic activity than in a large institution. The social and economic advantages of home and foster-home care of rheumatic children are obvious. The Boston experiment has shown that on medical grounds such children are at no disadvantage compared with those in special institutions. No complete answer to Dr. Paul White's question—"Is all this worth while?"—is yet available. More time must pass before ultimate effects upon mortality and morbidity can be assessed. Meanwhile, for those health authorities in this country who have no special "heart home" or similar institutions available, the Boston work indicates a clear line of approach to the problem.

TREATMENT OF TUBERCULOSIS BY ARREST OF LUNG MOVEMENT

Several factors, including restricted movement of the lung, may contribute toward the good effects of pneumothorax therapy. Nevertheless a considerable excursion of the collapsed lung continues to take place with each respiratory cycle. Complete arrest of such movement with retention of function is, however, no longer merely a therapist's flight of fancy. Alvan L. Barach has recently described⁵ the mechanism of alternating-pressure respiration. He has shown that in patients with pulmonary disease treated in a

¹ *Subacute and Chronic Pericardial and Myocardial Lesions due to Non-infectious Causes*, London, 1938.

² *New Eng. J. Med.*, 1941, 284, 602, 603, 604.

⁵ *Amer. Rev. Tuberc.*, 1940, 42, 556.

chamber by an alternating pressure of ± 55 mm. Hg twenty-five times a minute, as originally suggested by Thunberg² for respiratory paralysis, continuous arrest of lung movement could not be maintained. Moreover, compression and expansion of the chest resulted from the positive and negative cycles of pressure. The failure to arrest lung movement was found to be due mainly to the resistance interposed by the tracheobronchial tree to the passage of air in and out of the lung. By artificially creating a like resistance to the air pressure applied to the chest wall, the pressure on the inner and outer surface of the thorax as well as the pressure on the upper and lower surfaces of the diaphragm were made approximately equal. Adequate ventilation of the lungs then occurred without voluntary breathing and without discernible movement of the ribs and diaphragm. The apparatus employed³ was called an equalizing alternating pressure chamber; an equalizing pressure of between 5 and 6 cm. of water was found most satisfactory. Barach now reports⁴ on the treatment by this method at the Presbyterian Hospital, New York, of five patients with advanced bilateral pulmonary tuberculosis. These patients, after a previous control period of bed rest, were considered unsuitable for any type of collapse therapy. The procedure was found feasible in all of them. One, after failure of a pneumothorax subsequent to the treatment, wished to return; another was glad to come back for a second course. "Despite intermittent boredom with the routine, the co-operation which these ward patients gave was an indication of the practicability of the method." The first patient was treated for two months for about six hours a day; the others were exposed to the local lung rest for twelve or thirteen hours daily, being taken out of the chamber for lunch, dinner, and for milk and orange juice at 4 p.m. The duration of the treatment was arbitrarily set at three months. Complete healing was not expected to take place in this length of time, but it was hoped that a recovery process might be initiated which would then continue with ordinary rest in bed. The detailed case histories leave no doubt about the beneficial effect of the treatment on four of the patients. Moreover, in one of them there was resolution of an extensive tuberculous process characterized by honeycombing in both lungs. The sputum has remained negative for a year, and he is now doing part-time work which calls for mild physical activity. In another patient, who had had a cavity for ten years, there was both clinical and radiological improvement. His sputum and, later, gastric contents have remained negative for two months after discharge. The results of the application of this method in less advanced cases of pulmonary tuberculosis will be eagerly awaited. But as the originator of the method himself stresses: "It should be understood that subsequent treatment must still utilize the measures known to be of value in pulmonary tuberculosis."

THE ROTUNDA TO-DAY

The Rotunda of Dublin is one of our most renowned maternity hospitals, and its long record of distinguished service has been surpassed by none. Like many another it had been growing structurally decrepit for many years, but its work was continually inspired by the love of progress and by the spirit of youth throughout the long series of live and able Masters who have guided its activities. And now a turn of the winged wheel of fortune—or its modern unromantic equivalent, the lottery drum—has furnished it with an environment worthy of its undaunted

spirit. In other words, the Rotunda has been rebuilt and reconditioned by means of an allocation of £160,000 received from the Irish Hospitals Sweepstakes Fund. In this island the intangible force which is described (often inaccurately) as "public opinion" has been opposed to the device of enlisting the average man's love of "taking a chance" in the service of charitable institutions, even of those which are of proven value. It is, however, quite possible that treasurers of hospitals, glooming over empty coffers, would willingly exchange the glow of moral and financial rectitude, which they are entitled to enjoy if they can, for the spate of sterling which has submerged the overdrafts of many of the hospitals of the neighbouring island. No one, we feel sure, will be disposed to cavil at the good fortune which has befallen the Rotunda, for it has enabled that hospital to provide a new nurses' home and students' quarters, new sterilizing, radiological, and operating equipment, and to redecorate and recondition the old buildings. In addition to all this a Social Service Department has been set up which has made a promising start and should do valuable work in developing those intimate personal relations that should exist between a voluntary hospital and the people of the district it serves. A notable feature of the accounts of nearly all voluntary hospitals is the annual deficit. This phenomenon, while it may vary in size, recurs with the utmost regularity and is generally regarded with equanimity by boards of management. For certain purposes the deficit has come to be viewed as an asset and accorded a measure of publicity rather than relegated to the proverbial cupboard. When the time is judged to be ripe for launching the periodical appeal for money the size of the deficit becomes a "bull-point" in its favour, and there may even appear a tendency for one hospital to vie with another in parading financial stringency. From these somewhat undignified devices, which are regretted by many friends of voluntary hospitals, the Rotunda of Dublin is saved, for the annual deficit is regularly liquidated by another turn of the lottery handle. Under such conditions financing a hospital must lack the thrill which approach to the verge of bankruptcy produces in the minds of persons accustomed to pay their way. Substantially, however, the Rotunda and other hospitals in similar case are gainers, for their work is not hampered by inability to meet the rapidly increasing cost of caring for the sick in accordance with changing therapeutic and surgical methods. The Rotunda report for 1940, written by the retiring Master, Dr. Andrew H. Davidson, tells a tale of progress which is truly remarkable and well deserves public attention. During his seven years' term of office the number of deliveries in hospital increased by 40%, and the proportion of patients who received ante-natal care rose from 44% to 79% in the same period. It is not to be supposed that the lure of a modernized hospital was the sole cause of this remarkable advance, and full credit will be given to the outgoing Master and his assistants for the high level of efficiency which characterized their work.

THE HALF-YEARLY INDEXES

The usual half-yearly indexes to the *Journal* and to the *Supplement* are now ready. They will, however, not be issued with all copies of the *Journal*, but only to those readers who ask for them. Any member or subscriber who wishes to have one or both of the indexes can obtain what he wants, post free, by sending a postcard notifying his desire to the Accountant, British Medical Association House, Tavistock Square, W.C.1. Those wishing to receive the indexes regularly as published should intimate this.

A SURVEY OF WAR SURGERY*

BY

L. R. BROSTER, D.M., M.Ch., F.R.C.S.

Surgeon to Charing Cross Hospital

The principles of surgery are continually being enriched by new methods which stand the test of time, but in war-time fresh problems are imposed with such insistence as to demand immediate attention, and often hasty improvisation. It has been delightful to see the enthusiastic reception which has greeted the presentation of our difficulties and the genuine desire to get to work on their solution which has been displayed by the profession both in the United States of America and in Canada. At the outset it may be said that the surgical principles laid down as a result of the last war have stood the test of time, and have remained the sheet-anchor of present procedures; but before surgery can be established on a satisfactory basis it is necessary to consider some of the points in its organization.

Medical Organization

The medical organization for this war has been devised on lines different from those of the last. The policy adopted has been the formation of the Emergency Medical Service for the whole country under the Ministry of Health. Hospitals have been decentralized and re-created as sector hospitals in the countryside, and are responsible for the treatment of sick and wounded, both civil and military, although the existing Service hospitals have carried on as usual. Many of these outlying hospitals have been converted into "special hospitals," such as centres for head injuries, chest injuries, plastic surgery, and orthopaedic surgery. Before the war actually started the medical profession had been voluntarily conscripted. This work was undertaken by the British Medical Association. Every member was card-indexed and his wishes for service consulted, with the result that the Central Medical War Committee is able to satisfy from this pool any demand by the State in the way of personnel in any direction. The staffs of the voluntary and larger city hospitals have been used in manning the outlying sector hospitals. Apart from the inconveniences and the dislocation caused by the migration of large numbers of town folk to the countryside, the health of the population, in spite of rationing and overcrowding in shelters, has remained very good, and we have been free from epidemics. One of the anomalies has been that the health of the children who have remained at home has been better than that of those who have been evacuated. Although such a system has its limitations, as a wartime measure which has now become established it is running fairly smoothly and efficiently.

War Wounds

Early and free surgical excision still remains the basic, and most satisfactory, procedure in the treatment of all war wounds, and although the open Carrel-Dakin method is occasionally employed, the most important change has been the adoption of the closed-plaster method of Winnett Orr and Trueta and the use of drugs of the sulphonamide group for combating infection. The consensus of surgical opinion is that the combination of excision, closed plaster, and sulphonamides has proved a great advance in the treatment of war wounds.

Where this method has been used, as at Dunkirk, the wounded have arrived back in good condition and the wounds have been clean. It gives the maximum of com-

fort and eliminates many of the difficulties of transport. Morale is high, and there is practically none of that distressing condition of "shell-shock" which was so prevalent among the wounded from the trenches during the last war. There is no doubt that the closed-plaster method is a boon to the patient; it gives comfort and rest, and eliminates the dread of the painful daily dressings of the open method. Its greatest objection is the obnoxious smell. However, it requires constant supervision, for on the appearance of a raised pulse or temperature, pain, sleeplessness, loss of appetite, oedema, or coldness of the toes, the plaster should be removed. Where this close observation has not been possible some cases have arrived with spreading infection, sometimes anaerobic, and gangrene beneath the plaster. Under such conditions some surgeons prefer to transport their patients with a peeping window cut in the plaster over the wound, or, if the distances are short, to dispense with it altogether—as in such cases as fractures of the lower limb, in which the Thomas splint with traction has again proved its value.

With regard to sulphonamides, these can be employed in two ways—prophylactically, or locally into the wounds: by mouth, starting with 2 grammes followed by 1 gramme four-hourly up to a total of 20 grammes, or by direct insufflation into the wound in doses varying from 5 to 20 grammes. Experience has confirmed that more satisfactory results are obtained with local application. The chief aim is to get the wounded to the nearest surgical unit within twelve hours, and in these days of mechanized and aerial transport this ideal should be increasingly realized. In hospital the primary considerations are the arrest of haemorrhage and the treatment of shock, whether primary or secondary. It is only then that excision should be carried out. This requires the removal, not too wide, of skin, all devitalized muscle and fascia, and detached fragments of bone and foreign material, so as to obtain a saucer-like wound, which is the most satisfactory for drainage. The more urgent call for early excision is in wounds of entry into fleshy parts with retained missile. In multiple wounds the larger ones only need be excised, as also those wounds complicated by fractures or involvement of joints. Although primary suture of the larger wounds after the application of sulphonamides may be carried out within twelve hours, the general impression is against this procedure. On the other hand, some surgeons have reported success from primary suture in wounds two to three days old, but as infection has already taken place in these late cases formal excision is not indicated: the wound should be opened to provide free drainage, necrotic muscle and retained missiles removed, sulphanilamide introduced, the wound covered with vaselined gauze, and the limb encased in plaster or splinted. When infection has been overcome secondary suture can be undertaken.

Bomb Injuries

Fortunately the number of wounded has not come up to expectation; a higher proportion are mortal, however, and this is reflected in the low percentage of survivals from abdominal and chest wounds in comparison with the more numerous wounds involving the limbs. There is not so much of that extensive ploughing up of the tissues from high explosive and shrapnel as in the last war, for the modern bomb is more destructive than maiming. Its casing is comparatively thin, and its terrific blast breaks this up into numerous small hot fragments which spread out fan-wise in a more or less horizontal direction with low trajectory. Wounding is more common from the secondary effects of the blast, either from shattered glass or from falling masonry. Consequently we may stigmatize this war of aerial bombardment as one of multiple injuries and

* The basis of an address delivered by invitation to the American Surgical Association, at their Annual Meeting at White Sulphur Springs, West Virginia, May 29, 1941.

marked traumatic shock. It is often difficult, therefore, to determine which of these small multiple injuries involve the more important structures, such as vessels, nerves, and viscera; and they cannot be dismissed by their apparent triviality, for severe venous thrombosis may follow from infection driven into superficial veins, and nerve injuries in particular are apt to be overlooked.

Regional Injuries

It is impossible in a short paper of this kind to enter fully into the injuries of the different parts of the body, so a brief summary of the most salient points must suffice.

Head.—Four principles of general application may be cited here: (1) Remove infective material and dead brain tissue. (2) Remove blood clot, extradural or subdural, and aerocele. (3) Consider whether a retained foreign body should be removed on account of traumatic epilepsy. (4) There is a definite impression that the sulphonamides tend not only to localize infection but to delay the necessity for operation: this is therefore a hint towards the adoption of more conservative methods. The most important fact to be established is whether the dura has been penetrated or not, and every means should be employed to this end. When the dura is opened damage to nervous pathways, spread of infection to the ventricles and basal cisterna, later abscess, and epilepsy must be borne in mind. The dural wound should not be enlarged unless the surgeon is prepared to remove necrotic brain and clot to prevent tension, otherwise fungus of the brain will develop. Forceful irrigation and suction should be used for this, and at the same time all dirt, foreign bodies, and detached bone must be removed. Repair of the dura is unsafe, and tension should be controlled by repeated lumbar puncture. Retained missiles should be left alone, but if the clinical signs spread and the cerebrospinal protein content increases, bold measures for their removal should be undertaken. Compared with civil injuries, concussion is usually slight, but unconsciousness may occur late and be prolonged. Focal symptoms are frequent: they tend to recover, and operation is indicated only when they come on late.

Abdomen.—The mortality rate from abdominal wounds is high, and the principles of treatment remain fundamentally the same as during the last war. All undoubted peritoneal wounds must be operated on, and the mortality depends largely upon how soon this is achieved. Essentials for success are accurate localization of the missile, local patching instead of resections, and end-to-end anastomosis for preference, control of bleeding, cleaning out of the peritoneal cavity, and—rarely—drainage, except in late cases, and then suprapubically. Time and speed, too, are essential. Multiple ileostomies are of no value, but caecostomy may prove a useful outlet for distension. Sulphanilamide dusted on the suture line, and 5% of this powder, given with saline, into the peritoneal cavity, is a procedure that has been recommended by some surgeons. It is gratifying to hear that retroperitoneal haematoma, so fatal in the last war, has shown some recoveries with chemotherapy. Wounds of the liver, spleen, kidneys, and bladder should be treated on conservative lines. Abdomino-thoracic wounds, whether approached from the abdomen, thorax, or both, should ensure repair of the diaphragm. Late cases of peritonitis in which there is reasonable evidence of involvement of the bowel should be operated upon.

Chest.—Like wounds of the abdomen, chest wounds are of low incidence and high mortality. It is probable that a large number of these cases do not reach base hospitals. Operative intervention for haemorrhage from the parietes or lung should be undertaken at once. Open pneumothorax is the bugbear of these sucking wounds, and must

be stopped up at once by vaselined gauze dressings and strapped. Pressure pneumothorax can be gauged by trachea deviation radiologically and relieved by needling. Repeated aspiration should be performed for haemothorax, and, if infected, rib resection with closed drainage. Foreign bodies, unless large and in the dangerous area of the hilum of the lung and pericardium, are better left alone. For shock and loss of blood, plasma and whole blood are given in large quantities, up to 5 to 6 pints, the aim being to maintain the haemoglobin at about 80%. Oxygen given by the B.L.B. mask is invaluable. Local application of sulphanilamide into the wound is good, but the results of employing it in the pleural sac are as yet inconclusive.

Chemotherapy for War Wounds

Perhaps the most fascinating aspect of the treatment of modern war wounds is the advent of chemotherapy as an adjunct to surgery. Though the use of these sulphur compounds must still be regarded as in the experimental stage, there is a general consensus of opinion that where they have been employed wounds are less heavily infected and in a healthier state than corresponding wounds in the last war. Much experimental work has been done with sulphanilamide, sulphapyridine, and sulphathiazole. Colebrook considers that local application is superior to the oral route, and has higher expectations from the use of sulphadiazine. Fleming prefers sulphathiazole. The effects of these drugs have been most notable in the streptococcal infections, especially in the cleaning up of late wounds. The anaerobe group as a whole is less susceptible to their action, but it is fortunate that *B. welchii* is more susceptible than the other members of this group. Antitoxic sera have also given protection against these infections, but at the moment no comparative results, or results from combined sulphur and toxin prophylaxis, are available. It is considered that these substances, of varying solubility, act direct on bacteria and arrest their metabolism.

Burns

One of the curses of the internal combustion engine is the risk of burns, and the war has acutely accentuated the importance of this problem, which calls so much for teamwork and treatment from different points of view. The tannic-acid method, devised by Davidson of Detroit in 1925, so successful before the war, led to neglect in the study of some of its pathological problems. War burns present special difficulties of their own, in which the primary objects are to save life and limb and to preserve function. The main cause of dissatisfaction with the tannic-acid treatment is that in the commonest types of burns—i.e., those involving the face and hands of airmen—it has led to severe scarring and to gangrene of the fingers. There has followed a great deal of ingenuity in trying out new methods of treatment, but as yet no unanimity of opinion as to their respective values has been arrived at. They may be summarized as follows:

1. The Triple-dye Method.—This, consisting of gentian-violet 2%, brilliant green 1%, acriflavine 0.1%, is recommended by Rear-Admiral Wakeley, who claims that when sprayed on the burn it produces less scarring than tannic acid.
2. The Bunyan Bag.—In this method the burnt surface is isolated in a special watertight envelope, and is irrigated with electrolytic sodium hypochlorite solution (5% milton).
3. The Edinburgh school recommends the application of sulphanilamide and glycerin.
4. Saline baths.

If tannic acid has been found unsatisfactory for certain forms of burns it must not be concluded that it should be discontinued. Outside the areas of the extremities and

flexures it still has firm and ardent advocates, and is considered by many the best form of treatment when applied over a burn dusted with sulphanilamide. Whatever method is decided upon, the burnt area should be thoroughly cleaned with saline and dried with hot air. For this purpose gas-and-oxygen, evipan, and pentothal are the most satisfactory forms of anaesthesia. When the tan falls off in the course of a few weeks the part should be rubbed with lanolin, and any cracks in it can be dusted with sulphanilamide. Tanning has reduced streptococcal infection, but where this is present in late cases the tan should be removed and saline baths given. From the point of view of the plastic surgeon, the school led by Gillies insist that such treatment is satisfactory only for burns of the first and second degrees. For burns of the third degree they recommend surgical excision of the burn, saline baths, and Thiersch grafting as soon as a satisfactory granulating surface has been obtained. By these means unnecessary scarring and deformity are avoided.

Apart from the treatment of the actual burn, it is in dealing with its complications that work is so desirable. Primary shock has a mortality rate of 2% to 3%, whereas secondary shock, which comes on later, has a danger-point during the subsequent twenty-four to forty-eight hours, with mortality as high as 60%. Unless there has been concomitant haemorrhage, blood transfusion is not indicated owing to the concentration of the blood which occurs, and blood plasma must be given to replace protein loss and prevent oedema.

Blast Injuries

The highly explosive force due to the sudden conversion into gases of solid material under great pressure within the modern bomb has given rise to a series of phenomena which have come to be known as "blast injuries." Blast has shown curious anomalies in its direction, distribution, and force. It is probable that these are due to the breaking of the casing at its weakest point and to the waves of pressure being ricocheted or reflected by buildings in the vicinity of the explosion. The effects of blast on animals have been studied by Zuckerman. A wave of high-positive-pressure velocity is created, and this is followed by another of negative decreased velocity exerting a suction-like action. The high-pressure wave falls to atmospheric pressure over a distance of some thirty feet, but proximity to the actual blast does not necessarily determine its effects upon its victims. Usually it gives rise to no surface injury, and is characterized by blood-stained froth at the mouth, which may appear sooner or later, but within ten days. Clinical examination of the chest reveals the signs of pneumonia. Necropsy discloses haemorrhage of varying extent in the substance of the lungs. Similar haemorrhages may also be found in the liver, spleen, intestines, adrenals, kidneys, bladder, and, seldom, the brain. The force of the blast may hurl people against objects and so give rise to secondary injuries, which may cause the blast injury to be overlooked. Fat embolism is also sometimes found at necropsy.

From the surgical point of view these patients give rise to much anxiety. Like pleurisy, the chest condition is often associated with rigidity of the abdomen, and yet due regard must be paid to the possibility of a concomitant intra-abdominal lesion, while in either case inhalation anaesthesia is best avoided.

Crush Injuries

Different methods of warfare either bring new problems or revive old ones in new disguise, and the crush syndrome may well fall into either category. It is characterized by acute renal failure supervening in people who have been pinned down by fallen masonry and have been buried and subjected to pressure for a varying period. There may be

no evidence of any local injury, but, when there is injury, local swelling, oedema, whealing followed by bullous eruption, and patchy areas of anaesthesia appear. A few hours later, in spite of vasoconstriction as shown by pallor, coldness, and sweating, the blood pressure falls and haemoconcentration rises. Later the urinary output diminishes, and albumin and dark brown clots appear in the urine. The patient becomes alternately alert and drowsy, and his blood pressure often rises. Oedema, vomiting, and thirst supervene, the blood urea and potassium become increasingly high, and death takes place about the seventh day. Post-mortem examination shows necrosis of muscle, and cloudy swelling and degeneration of the renal tubules.

Shock

"Shell-shock" to those who knew it during the last war has taken a holiday, and has been replaced by traumatic shock of varying and severe degree; for, apart from wounds, it is a handmaiden to burns, blast, and crush injuries. There is little new to add to the question of shock; but from the observation of cases of uncomplicated shock at Charing Cross Hospital the following points may be stressed. The mental state of the patients, all of whom had received morphine, was quiet and still; very few of them were excited. In general they were pale, dry-skinned, and thirsty; one patient sweated profusely. Some had nausea and vomiting. The pulse was never above 100: its quality varied, being thin, impalpable, or collapsing. In all cases the blood pressure was below 100. A rise of 10 points in blood pressure, and improved temperature and colour and mental state, were taken as indications to warrant surgical intervention. As a rule the need for transfusion was in proportion to the severity of the injuries. Plasma was given, and whole blood if haemorrhage had occurred. In severe shock transfusion may be difficult owing to the collapsed condition of the veins, and local warming of the arm has proved helpful in getting the blood in satisfactorily. The organization of the blood transfusion service has been one of the main successes of our hospital system, and the prompt access to reserves of stored blood has been most helpful and has resulted in the saving of many lives.

HEALTH PROBLEMS IN HONG KONG

According to the report for 1939 of the Director of Medical Services, Hong Kong, the large numbers of Chinese refugees from the neighbouring Sino-Japanese conflict continue to constitute the colony's chief health problem. In July, 1939, the number of persons entering the colony exceeded the number leaving by 327,833. Many of the immigrants are destitute, ill nourished, and diseased, and the overcrowded conditions in which they live are, after malnutrition, the most serious menace to public health. A deputy director of health services was appointed at the end of 1939, and the sanitary inspectorate has been transferred to the direct control of the health officers, so that the much-needed organization of the health services of the colony can now take place. Diseases of the respiratory system (non-tuberculous) caused the largest number of deaths in 1939. Tuberculosis came second, as in 1938, the pulmonary form of the disease being responsible for the majority of the deaths. A blood survey of 1,500 refugees showed a malarial infection of 24%. There were over 9,000 cases of beriberi, 800 cases of cholera, and 3,000 of influenza in Hong Kong during the year under review. In no other part of the British Empire is there more need for active sanitary measures, and, as the report shows, it is only by persistent vigilance that the D.M.S. (Dr. Selwyn Clarke) and his large staff can cope with the problem of maintaining a reasonable standard of public health among the 1,500,000 British and Chinese inhabitants of the colony.

PLANNING FOR MENTAL HEALTH

REPORT OF B.M.A. COMMITTEE

Three years ago the Council of the British Medical Association set up a committee to inquire into the present medical equipment and provision for dealing with mental health, with special reference to the treatment and prophylaxis of psychoneurotic and allied disorders. The chairman of the committee was Colonel R. G. Gordon, M.D., of Bath, and its twenty-two members included a nominee of the Royal Medico-Psychological Association and of the Society of Medical Officers of Health. As an example of the thoroughness with which the subject has been surveyed, 170 persons, organizations, or institutions were drawn upon for evidence or for information furnished in other ways. The committee had virtually completed its work before the outbreak of war; only the consideration of its report remained, and it was thought well to finish this. It has now been published as a B.M.A. "Grey Book" of fifty pages. So far from having been rendered untimely by the war, it derives a new interest on that account, and it will be of first importance to the Medical Planning Commission.

It may be recalled that at the Annual Representative Meeting at Aberdeen two years ago this same Mental Health Committee brought forward certain advance recommendations regarding the "non-medical psychotherapist," setting out the conditions under which he might undertake treatment and those under which a medical practitioner might recommend a patient to him, and calling for a two-years training of such lay people on the basis of an agreed curriculum. After an interesting debate¹ the objections to the recognition of lay psychotherapists prevailed, and the recommendations were turned down. In its report the committee now only makes the comment that if no non-medical psychotherapists are to be recognized by the medical profession it becomes all the more urgent to train enough medical psychotherapists to cope with the demand.²

The Dimensions of the Problem

The inquiry of the committee was chiefly directed to the psychoneuroses, but it could not leave the psychotic cases out of its consideration, nor, on the other hand, could mental deficiency be omitted from any discussion of mental illness, and the same applies to many cases of drug addiction and to epileptic manifestations. The committee found it impossible to define exactly any criterion of mental illness. "It would seem that at present one must depend chiefly on the manifestation of symptoms rather than on more scientific criteria in diagnosing such disorder." Equally, mental illness cannot be divorced from physical illness. In all illness there are psychic and somatic components which must be considered in relation to each other.

The incidence of mental illness is difficult to ascertain. In 1938 there were 158,723 persons suffering from mental disorder notified as under care in England and Wales, and 89,904 mentally defective persons in institutions and under statutory supervision. But the group with which the committee is more concerned is that of persons suffering from mental illness who have not been certified. In many parts of the country there is no one in private or hospital practice to care for such patients. The committee does not seem to have been much helped by its witnesses in this assessment. One witness declared that quite 60% of the population were psychoneurotic; another that while the number of psychoneurotics was larger than generally supposed, the difficulties of many of them were negligible and could be cleared up in a single interview; while another spoke of the "danger that

we may fall into a new fashion of medicine where almost every ill will be attributed to mental factors." The attempt to obtain records of the incidence of psychoneurosis from general practitioners who were known to be interested in the subject did not yield anything of statistical value, but a number of experiences are quoted from clinics and departments. The most informative figures are those for nervous debility and neurasthenia and neurosis in the returns of the Department of Health for Scotland of incapacitating sickness in the insured population, but even these do not show the whole number, for many cases are likely to be included under such headings as anaemia, gastritis, and rheumatism. As for the incidence of psychoneurosis in industrial injuries, the number of compensation cases in the seven great industries in Great Britain is just under 500,000 a year, and if only 2% showed psychoneurosis it would mean 10,000 cases.

The committee concludes that the incidence of mental illness is much greater than can be met by present facilities for treatment, that in any group of sick persons something like 30% will be found suffering from conditions about which it would be helpful to have psychiatric advice if not treatment, that it is important that they should be dealt with by persons well trained in psychological medicine, and that therefore the number of doctors with such training (at present an inadequate number) should be much increased.

The causes of mental illness are grouped under the headings of: (1) hereditary and constitutional; (2) environmental emotional factors in early life; (3) similar factors at the time of the illness. Hereditary and constitutional factors are causal in many cases of mental deficiency and important in the non-organic psychoses, especially in the manic-depressive group, while as to psychoneurosis, the figures show that in families of severely psychoneurotic patients there are two or three times as many psychopathic, psychoneurotic, and psychotic persons as in the average normal family. Economic status in itself is not considered as a very important factor.

Present Means of Prevention, Diagnosis, and Treatment

The greatest preventive measure is public education in mental health, and a survey is given of the work done by the Tavistock Clinic, the National Council for Mental Hygiene, the Central Association for Mental Welfare, the Child Guidance Council, and other bodies. Education of mothers, nurses, and teachers in the management of young children would materially lessen the incidence of psychoneurosis. So would educational measures directed to training the growing child how to live and to manage his instinctive urges. It is important to bring home the need for seeking advice in the early stages of mental illness; the most effective education in this respect is the evidence of good treatment at the psychiatric clinics. Finally, there is the urgent requirement for the better education of the general practitioner so that he may protect and guide his patients from their earliest years.

In-patient provision for chronic psychotic patients is reasonably efficient, but there is great need for specialized accommodation and treatment for patients acutely ill and with a prospect of recovery. Out-patient treatment suitable for slight and early cases is improving; there are now 187 local authority clinics in Great Britain which deal with mild psychotics. But in-patient provision for the psychoneuroses is seriously inadequate, and there is no special provision for chronic psychoneurotic patients, who constitute a serious social problem. Child guidance clinics number fifty-eight, but not quite half of them are (or were, in 1938) employing a full team—that is, a psychiatrist, a psychologist, and a psychiatric social worker. The committee does not regard with favour centres established exclusively for psychoneuroses arising under industrial conditions, apart from rehabilitation for physical disabilities.

The number of local authority institutions for defectives is increasing, but a considerable number of defectives are not "ascertained." Provision for persons addicted to alcohol or drugs is most inadequate, and doctors as a whole are not educated to treat this small but important group of patients. The committee recommends that some compulsory procedure be legally enacted to enable such patients to be effectively treated. Better arrangements are now being made for the treatment of delinquents; prisoners are observed with psychological

¹ Supplement, August 5, 1939, p. 113.

² A "psychotherapist," by the definition in the report, is a specially trained registered medical practitioner who in treatment employs wholly or predominantly methods of mental analysis, suggestion, persuasion, or re-education directed to rectification of abnormal mental states. A "psychiatrist" is a specially trained registered medical practitioner who devotes himself wholly or predominantly to the care and treatment of mental illness, including every form of mental deviation. A "psychologist," in the field of mental health, is a person with a university or equivalent training in psychology, who assesses intellectual capacity, gives remedial teaching and vocational guidance, and treats educational disabilities.

understanding, and facilities for special treatment can usually be granted.

The committee adds that in order to bring out-patient provision for mental illness up to a satisfactory level, many more medical practitioners should be trained in modern psychiatry, and because of the length of time required for psychological treatment it is necessary, if these practitioners are to obtain a livelihood, that paid part-time posts in clinics should be established. It is convinced that treatment, including psychotherapy, increases the number of those who recover or are enabled to make a reasonably satisfactory adjustment. Sufficient evidence has not been obtained to enable the value of various forms of psychotherapy to be assessed, and perhaps Janet's dictum that "the psychologist who understands his patient well and who knows how to use psychological stimulation succeeds with any method he cares to use" cannot yet be superseded. Only a small proportion of patients call for intensive or prolonged analytical treatment, though the committee is satisfied that such cases do exist.

Model Scheme for Treatment of Mental Illness

Seven pages of the report are occupied with a model scheme for the treatment of mental illness. A properly organized Mental Health Service would include the following:

1. Provision for investigating and treating adult patients suffering from psychoneurosis, psychosis, delinquency, drug addiction, and epilepsy, and for the care of mental defectives.
2. Provision for the development and adjustment of children presenting all varieties of psychological and psychosomatic problems.
3. A central advisory committee for each area, to include representatives of voluntary hospitals, medical schools, organizations dealing with mental health and defect, and educational and health representatives from public authorities. County councils should be pressed to form mental health committees in association with, but having a separate organization from, their public health committees.

In-patient services will include:

1. A ward in the general hospital, in charge of a psychiatrist, for psychoneurotics and mild psychotics.
2. Special psychiatric hospitals, which in the larger centres would include hospitals for psychoneurotics and mild psychotics, with attached out-patient units, and also acute units which would receive all police and observation cases, chiefly temporary and certified.
3. Institutions for long-continued and chronic cases, which would include separate hospitals or blocks for psychotic cases, though with staffing and administration under the same control as the provision for acute recoverable cases; also special provision for chronic psychoneurotics and addicts, and, of course, institutions for mental defectives.

Out-patient services will include clinics at the general and special hospitals, and at municipal hospitals where necessary, child guidance clinics, and mental defective training units. Properly organized laboratory services are one of the great needs of mental health, and laboratories, which might be grouped, should have the services of a full-time pathologist, with specialist assistants. All these clinics and units should co-operate as much as possible for organized research and medical teaching and the training of members of the ancillary services. The scheme is represented diagrammatically in the report. In the middle is the central psychiatric unit, including divisions for mild and acute cases. It is fed from the out-patient department, which has three sections—adults, children, and delinquents—and from the general hospital, and cases proceed from it to the rehabilitation and convalescent centre or to the mental hospital with its provision for recoverable cases and for chronic psychoneurotics.

Normally adult diagnostic and out-patient treatment clinics will not be separated. They should be staffed by a psychiatrist paid on a sessional basis and, where possible, a whole-time psychiatric social worker. An occupational therapist, and in some cases a speech therapist, should be attached. At least two sessions a week must be held, as many patients will require to be seen twice weekly. A scheme for diagnostic service and the

treatment of the milder cases will eventually be necessary in the more remote country districts. This might be modelled on existing orthopaedic schemes, with central and outlying clinics, the latter to be visited at stated intervals. Adult in-patient clinics for mild cases might be "central" to a group of diagnostic and out-patient treatment clinics, and the same location might serve for both adult and juvenile cases provided that there were separate children's wards; Maudsley Hospital is cited as a good example. Acute cases and chronic and probably irrecoverable cases should be treated in different institutions, which may be jointly staffed. In the acute block there should be adequate facilities for all modern psychiatric diagnosis and treatment, including psychotherapy, hydrotherapy, occupational therapy, and the various forms of shock therapy.

Other recommendations by the committee are that in view of the large number of patients among the general medical sick who would benefit from psychiatric advice and treatment, every hospital of more than 100 beds should have on its staff at least one physician in psychological medicine with an appropriate status. A diagnosis or treatment clinic conducted by a general hospital should be separate from the neurological department, so that due recognition may be given to the relation between psychological and general medicine. Approved societies and the Ministry of Health should be asked to make out-patient psychiatric treatment an additional medical benefit, and the Ministry to make a grant towards an extension of psychiatric services. The need for special training institutions or colonies for persons of subnormal intellectual capacity, not amounting to certifiable mental deficiency, is pointed out. Often in these cases the only hope of satisfactory rehabilitation is in readjustment of environment. In the case of mental defectives a serious gap in provision is that many defective children who have not been "ascertained" leave school at 14 or 15, and as they have not been to special schools they are not notified and do not come under the Mental Deficiency Act until they may be "subject to be dealt with" after the age of 16. There is also no real provision in the way of institutional accommodation and community care for so-called moral defectives over that age.

Training of Personnel

The doctor is not sufficiently trained in the psychological aspects of medicine, and in this respect Great Britain is considerably behind other countries. The need for increased instruction receives practically unanimous support from psychiatrists. For graduates who wish to take the subject as a specialty the portal of entry is the diploma in psychological medicine, but this should be followed by prolonged clinical experience under supervision and control, preferably in residential appointments in psychiatric clinics or mental hospitals. Eventually psychological medicine should be raised to such a status as to warrant the award of a registrable qualification in the specialty by all medical schools. Many practitioners, however, who do not desire to pursue the subject as a specialty feel the need for further psychiatric knowledge to help them in their practice, and there is a growing demand for postgraduate courses in which the subject may be dealt with at greater length and more elaborately than in those which have been provided for insurance practitioners.

With regard to undergraduate training, the committee feels that the recommendations of the General Medical Council in 1936 are too vague and leave individual schools with too much latitude. The general object should be not to produce specialists in psychological medicine but to make students realize how the subject is integrated with general medicine. The preclinical instruction should be termed "medical psychology" instead of "normal psychology," and should be given by a psychiatrist, with relation to physiology on the one hand and to subsequent clinical studies on the other. Of twenty-two medical schools, nine at present give instruction in psychological medicine during the pre-clinical years. During the clinical years a three-months or six-months compulsory clinical clerkship in a psychiatric out-patient department is recommended. A good deal of teaching in psychotherapy and in other branches of psychiatry is practicable by demonstrations and discussions as well as by direct clinical work. The final examination should include a paper or at least questions on and a clinical examination in psychological medicine, and the examining boards should include psychiatric specialists. An

important part of the student's training should be to recognize the psychological aspects of the cases he meets in the general wards and out-patient departments.

The report concludes with a chapter on ancillary services—namely, mental nurses, psychologists, occupational therapists, psychiatric social workers, speech therapists, and, in children's work, playroom supervisors. General approval is given to the conclusions and recommendations of the Feversham Committee. The necessity that all workers in these ancillary services should have an adequate general education is stressed, together with the need for more facilities for the training of all nurses, especially mental nurses, in the management of psychoneuroses. In all the ancillary services a standard curriculum should be laid down for training and diplomas given to those passing examinations, and the members should be encouraged to form themselves into associations for the purposes of maintaining standards and securing adequate recognition, status, and remuneration.

The report is useful not only as embodying the views of this highly expert committee but also for the information it so concisely conveys.

Local News

SOUTH AFRICA

Health in the Witwatersrand Mines

The Health Department of the Central Mining-Rand Mines Group, of which Dr. A. J. Orenstein, a Vice-President of the British Medical Association, is chief medical officer, has issued a report for 1940 above the name of Dr. H. Q. F. Thompson, Dr. Orenstein being on active service. The average number of natives employed on the gold mines of the group during the year was 109,397, but, of course, a very much larger number were actually at risk for various periods. The number of shifts lost through disease or accident was 4.78 per native employed. The deaths from all forms of accident numbered 252. The mortality rate, 3.38 per 1,000 employed, was slightly higher than in 1939, but is still satisfactory, being much below the figures for earlier years. There was an increase in the number of cases of such respiratory diseases as pneumonia, influenza, and pleurisy, which is ascribed to the large influx of new labour. Pulmonary tuberculosis is also on the increase; silicosis remains stationary.

An Experiment with Sulphapyridine

Sulphapyridine has been used in the mine hospitals on the Rand as a routine therapeutic agent for pneumonia since the end of 1938, and the report states that it has undoubtedly contributed to the reduction in the death rate. The mortality figures for the four most recent years are as follows:

	Pneumonia Deaths	Per 1,000 Employed per Annum	Case Mortality Rate %
1937	308	2.94	11.58
1938	242	2.28	9.43
1939	56	0.55	2.61
1940	69	0.63	2.75

In 1936 pneumonia accounted for nearly 37% of deaths from all causes, whereas in 1940 this percentage was only 11. An experiment was carried out, beginning at the end of 1938 and concluding in 1940, on the treatment of pneumonia in native mine labourers employed at the Crown Mines. There were 200 cases, 100 of which received sulphapyridine and 100 acted as controls, receiving the ordinary symptomatic treatment. About half the cases had been previously inoculated with an auto-genous vaccine, but as these fell half in the treated group and half in the control they may be eliminated. There were two deaths in each group; of the two in the treated group, one of the patients had not responded to the drug at all, and the other, though recovering from the pneumonia, died of diabetes a week later. There was vomiting in only one of the 100 cases, and there were no other untoward effects of the drug. Complications arose in one case in the treated group and in four in the control.

The conclusions are that sulphapyridine does not appear to produce toxic symptoms in native males, even when larger doses are employed (the average dose given was 50.81 tablets or 25.4 grammes); that the period of pyrexia in pneumonia is reduced by the use of the drug, with consequent shortening of the stay in hospital (the average number of days in hospital was 15.20 in the treated group and 16.76 in the control; and it is the custom on the Crown Mines to keep every pneumonia patient in hospital for seven days after the temperature is normal, with a total minimum stay of 14 days); that the general discomfort of the patient is reduced, none of the treated group requiring sleeping draughts; and that pneumonia patients do not lose as much weight when treated with this drug.

Health in the Union

The annual report of the Department of Public Health, Union of South Africa, for 1939-40 deals with a population of over 10,000,000, including more than 2,000,000 Europeans. Among the latter heart disease occupies first place as the cause of death, cancer second, and pneumonia third. The death rate from the last named is the lowest for the past twenty years, possibly as a result of the introduction of sulphapyridine. It is stated that the statistics concerning the coloured population are still woefully deficient, but in the larger urban areas, where they are available, they show a very high infant mortality rate among natives. This is chiefly due to gastro-enteritis and respiratory diseases, in which ignorance and malnutrition are predisposing factors. Forty-seven cases of human plague with twenty-six deaths were reported during the year under review. Most of these occurred in the northern parts of the Orange Free State, but a small outbreak in the Vereeniging district of the Transvaal constituted the nearest approach of the disease to Johannesburg. The majority of the cases were bubonic, a few being septicaemic; one pneumonic outbreak occurred on a farm in the Orange Free State. Field surveys demonstrated the close relationship between mole-rats and gerbilles. All three species of the former were found to be susceptible to plague, so that these animals, despite the difference between their flea-fauna and that of the gerbilles, must be regarded as possible agents in the spread of infection.

Correspondence

British Medical Students' Association

SIR,—In view of the fact that the chairman of the Medical Planning Commission has asked the British Medical Students' Association to produce a memorandum on medical education, it may be of interest to your readers to hear something about the recent council meeting of that body. The main business on the agenda was the production of this memorandum, and a sub-committee was set up to promote study and discussion on the subject in all medical schools, to place previous memoranda of the B.M.S.A. and other relevant literature before medical societies, to prepare curricula, and to draft a representative and yet detailed and constructive document for presentation to the Medical Planning Commission. All students who are interested should communicate with Mr. K. C. Willett at the Middlesex Hospital, who will supply further information.

Student health questions were included in the reports from several medical schools and were discussed by council. It appears that in a few medical schools, notably University College Hospital, some effort is made to apply the principles of preventive medicine to student health. At these hospitals there is voluntary routine medical examination from the time of entry to the university, including yearly radiographic examination of the chest and Mantoux test conducted by the Prophit T.B. Survey. Hospital treatment is free or adapted to the student's means, and operation fees are unknown. Such conditions are too rare. In other schools there is no provision for medical examination at any time, and to request such examination other than on the basis of severe and unmistakable symptoms would be to invite the label "neurotic." In one base hospital it is reported that students are required to pay £4 4s. weekly under E.M.S. regula-

tions for a bed in a general ward. The result of such policy is shown in a report from a London hospital of seven cases of pulmonary tuberculosis, one fatal, occurring in a period of six months.

On the basis of reports and discussion the B.M.S.A. council unanimously passed the following resolution: B.M.S.A. approves the principle of free medical treatment of all medical students; this should include the attendance of doctors and hospital accommodation. Our policy is that every medical student should be examined on entry to the university, but that entry to the university should not be conditional on the examination. This examination should be the individual responsibility of the respective schools. The examination should be at regular intervals thereafter, and should include full radiographic examination of the chest. As an immediate measure it is recommended that schools apply for regular examination under the Prophit scheme for tuberculosis research (Royal College of Physicians).

Delegates drew the attention of council to the recent order of the Ministry of Labour making part-time military training compulsory for all medical students. This order seems to have been subject to considerable variation in application, and the reactions of delegates varied somewhat with the interpretation placed on the order by their respective deans. It is generally agreed that the primary duty of the medical student must be to get qualified as quickly as possible, but there are many students who feel that purely military activities are a waste of both time and equipment for future doctors, and that primary R.A.M.C. training, A.R.P. work, etc., would be a less incongruous form of war work. A great part of the difficulty is the failure of local authorities to utilize students effectively in A.R.P. schemes; and where students have fitted themselves into such schemes it has usually been in spite of the local authority.

Delegates from Scotland drew attention to the position of the students of the extramural colleges in Glasgow and Edinburgh. These students qualifying for the licence of the Triple Qualification Board have twenty-two weeks' holiday every year throughout their course, including a three-and-a-half-months summer vacation. They have been carrying on a vigorous campaign to obtain clinical teaching during the summer, but despite an appeal to the Ministry of Health they are still compelled to spend the summer haymaking, etc. Surely the six calendar years required by the G.M.C. for qualification would be better replaced by a minimum number of weeks' work if this is how the regulations are to be applied.

There was some discussion of the position of students taking house posts before qualification, but this was more in the nature of exchange of information about conditions, salaries, etc., and no specific recommendations were made by council.

The A.R.P. activities of the various medical schools were discussed when council was addressed by Dr. Sinclair Loutit, Medical Officer, Civil Defence, Finsbury, on "A.R.P. and the Student." The intrinsic difficulty in student relations with local authorities is the tendering of effective aid at the right moment without undue waste of time that should be spent in study. Some of the London hospital students combine first-aid work with a three-months casualty post. Students on these posts are required to sleep in hospital and be available at all hours; living expenses are paid, and the student is a unit in the E.M.S. for this period. Dr. J. Trueta addressed council on "The History of War Surgery." The lecture was illustrated by slides of his own cases and was enthusiastically received. The tone of the discussions throughout bore witness to the determination of students to play their part as best they may in present circumstances, at the same time keeping clearly before them ideals to be achieved in the post-war world.—I am, etc.,

C. M. TINKER,

Cambridge, Aug. 4.

Hypoprothrombinaemia

SIR,—In their paper on hypoprothrombinaemia and avitaminosis-K in this *Journal* (August 9, p. 190) Drs. Robert Kark and A. W. Souter have given a very comprehensive summary of the present clinical position of this problem. Inevitably, in dealing with such a wide subject in so short a space, they have cited as facts certain observations the import of which is still *sub judice*. Certain statements in their paragraph on hypoprothrombinaemia

in the newborn are open to criticism in the light of other investigations on this subject.

1. Shettles *et al.* (1939) showed that the prothrombin concentration apparently suffered greater reduction in the premature than in the mature infant, but Waddell and Lawson (1940), using Quick's method, were unable to confirm this. In explanation, it has been suggested that there may be some compensating factor present in the premature which facilitates the conversion of prothrombin into thrombin, so that there is but little difference from the mature infant in the "prothrombin time" in spite of a reduced prothrombin concentration. Our observations have shown that, using a method found to be entirely comparable with that of Quick, the only significant difference in the clotting activity (measured as the prothrombin index) in an unselected series of mature and premature infants has been a delayed onset and a slower rate of recovery in the prothrombin index after the initial fall, and seem to indicate that prematurity in itself is not an important factor in the production of "pathological hypoprothrombinaemia" in the newborn.

2. In the full-term infant the clinical and laboratory data obtained in these investigations during the past eighteen months point to the conclusion that it is rarely possible to attribute severe hypoprothrombinaemia in the newborn to post-natal conditions alone. It has been found that the usual methods of feeding or the use of glucose water have no effect on the initial fall, but do influence the occurrence and rate of the ensuing return towards normal.

3. The prothrombin index of the mother has been found to be consistently lower at the time of delivery than before or twenty-four hours after labour, and on two occasions has shown a definite deficiency at that time (Macpherson *et al.*, 1940). This constant reduction at the end of the second stage is probably in part due to the greatly increased katabolism which occurs during labour. Prolonged uncomplicated labour, however, has not been found to be a cause of abnormal prothrombin deficiency in the mother or baby at birth.

These observations have been recorded in greater detail in a report which will shortly be submitted for publication.—I am, etc.,

Edinburgh, Aug. 11

Air-raid Noises in Psychotherapy

SIR,—In the *Journal* of August 2 (p. 158) an article by Majors F. L. McLaughlin and W. M. Millar calls for some comments. The authors state that the employment of artificial noises is only part of the treatment, but do not sufficiently emphasize this point. They substitute a "conditioning," different from the neurotic reaction, by the employment of noises that startle the patient. They do not specify what they mean by "relaxation." Hysterical cases will always have some degree of dissociation, amounting frequently to a light hypnotic state; obsessional cases will be to some degree tense under any attempt to produce relaxation that stops short of a non-conscious state.

Reconditioning, or the substitution of another conditioning, is an excellent and often necessary auxiliary treatment, but it is only part of the treatment. The authors recognize this in the use of the word "abreaction," but do not give any definition of this term. In all cases falling within the group they designate there is a continual smouldering abreaction declaring itself to some degree. The use of any method to produce further abreaction is not, as was held during the last war, merely to "de-tension" by an escape of psychic pressure, but should have as its aim the gain by the individual of some significance of its causation and its suppression (defence mechanism against consciously knowing). This brings one to the main issue—always the same under any form of treatment that aims at lasting relief and control—namely, that of substituting a new significance or ideation with regard to stimulus and response and the concomitant reasoning of cause and effect. In order to do this it is necessary to employ two factors: (a) some definite psychopathology, and (b) an investigation of the fantasy-life in relation to the experiences of the earlier life-phases and functioning of the individual.

Everyone working with soldiers must have been struck by the difference between the toxic-exhaustive reactions of mere physical and physiological (metabolic) strains and stresses, which were adjusted in a few days, and the delay-action series of explosions which periodically erupt in the group of cases under review. Unless the earlier imaginative ideation or fantasy—a very real psychic phenomenon with potent motivation—is dealt with there is nothing to prevent the result of a purely “reconditioning” treatment from falling to pieces when later danger situations arise under circumstances where the individual realizes he is no longer in the safety-belt zone of a hospital with make-believe dangers. Conditioned states require constant reinforcement to keep them intact.

There appears to be a movement or policy afoot to deny the reality of psychoneurotic conditions. The civilian, who has been praised for his courage in the “front line,” is denied the right to a diagnosis of this condition, though those capable of making such a diagnosis are only too well aware of how many cases exist. Quite recently the *Times* has lent its columns to the movement (witness a leader “Health and Stress,” July 31). It is not a far cry from the civilian to the soldier, and signs are not lacking that the findings of E.M.S. psychiatrists are becoming unwelcome.

To the uninitiated or to those who would like to have it so this communication of the use of air-raid noises might be taken to be the main line of treatment. It would be a catastrophe if we regressed to an orientation to neurosis that prevailed during the last war, and the treatment of anxiety states were held to be only a reconditioning process.—I am, etc.,

Aug. 5.

J. C. MACKWOOD.

Mental Defectives in the Army

SIR,—After reading Dr. Esher's article in your issue of August 9 (p. 187), together with the editorial comment in the same issue, I believe the following remarks may be pertinent.

From experience at this colony of the capacity shown by mentally defective men to assimilate training in the simpler and semi-skilled trades, I should say that the mental age levels suggested for total refusal of enlistment and for enlistment into labour corps only are, each in its sphere, too high, though no one can quarrel with the principle of Dr. Esher's recommendation. It is possible that the use of the progressive matrices test in the Army (I believe this test is officially adopted) may account for the mental age levels of Dr. Esher's recommendation, for, using the progressive matrices test together with the older methods of assessment, I have never known the matrices test give the lower mental age figure, and have often noted that it gives a higher.

Accepting the principle, however, surely it would be good and practicable policy that all men refused enlistment by military service medical boards and those discharged as untrainable by reason of mental deficiency should be at once notified to their local mental deficiency authority. Their subsequent careers could then be supervised and, if necessary, controlled in the interests of social welfare and eugenics.—I am, etc.,

Brentry Colony, Bristol, Aug. 12.

JAMES JOHNSTON MASON.

Home Guard Medical Supplies from Canadian Red Cross

SIR,—You published some time ago (April 19, p. 604) a letter from the senior medical officer, Kent Zone, Home Guard, on a local scheme for the collection of Home Guard casualties in the event of invasion. The following further details, especially the equipment of these casualty collecting posts with medical supplies through the generosity of the Canadian Red Cross, may be of interest.

In that part of Kent with which I am associated a total of 180 posts have been established at farmhouses, private houses, churches, schools, garages, country inns, etc., no one being more than a mile from its neighbour. At the time the scheme was drawn up there was no indication from the War Office that any medical supplies would be forthcoming, and certainly not on the gigantic scale envisaged in those early days when a medical service for the Home Guard came into being. I was fortunate enough to obtain an interview with Colonel Scott, English Commandant of the Canadian Red Cross in this country, who was immediately sympathetic, and said he thought

supporters of the Red Cross in Canada would be more than pleased to know that some of the medical supplies and comforts they had so generously provided would be at the service of Home Guard casualties in this country. There and then he produced long lists of available Canadian Red Cross materials, and together we went through those lists with a view to picking out items most suitable for the collecting posts.

The next thing was the arrival at my headquarters of eighty packing cases full of medical stores, and 100 empty packing cases as well. With several other medical officers and a large working party of officers and men of the Home Guard, Whit Sunday was spent opening the Canadian cases and sorting out the contents so that each of the 180 cases should contain a like amount of first-aid supplies. Each case contained a large sterile tin, hermetically sealed, with several hundred dressings, a generous supply of blankets, triangular bandages, T-bandages, roller bandages, together with socks, pyjamas, pneumonia jackets, mattress pads, and surgical towels.

Each of the 180 crates was securely sealed and two stencils were used to paint on the following messages: (1) “Property of the Canadian Red Cross”; and (2) “Home Guard Dressings—for use in invasion only.” Thus every recipient knows to whom it really belongs, and exactly to what purpose its contents are to be put. They have also been informed verbally and by letter that if the contents are not used for the specific purpose for which the Canadian Red Cross granted them, they will have to be returned in good order to their generous donors. Since then a further small package has been sent to each post, and this contains the following: 10 grains of morphine in tablets (each containing 1/3 grain) suitable for placing under the tongue, a sterile tin containing several yards of vaselined gauze, and a dusting bottle containing a quantity of sulphanilamide powder. We have again to thank Colonel Scott and the generous people he represents for the last of these three items; the first two we were able to purchase thanks to the generosity of Mrs. M. F. Buckingham and a small contribution from each local district battalion fund.

Thus anyone who is wounded or injured or burned by flame-throwers in this part of the country will not have to walk, crawl, or be carried more than half a mile before adequate first-aid comforts will be available at a post, the exact location of which each man will be aware of beforehand. It should work out, then, that all wounded will be collected under one roof in each hamlet or village or district, and while the stress of battle continues wounds will be dressed, fresh clothing applied, pain alleviated, burns will receive antiseptic dressing and given suitable covering, and untold suffering avoided and lives saved, until such time as roads become passable for medical officers or ambulances. Thanks to the generosity of the Canadian Red Cross, the country areas of three hundred square miles of England which might, in time of combat, be quite beyond the reach of any other organization, have now the best-equipped casualty collecting posts for the Home Guard in the whole country. Each man is being taught as much first aid as possible so that he may help his wounded friend, and many of the posts are staffed by housewives who have had considerable nursing or first-aid experience.

I wish to express the warmest and deepest thanks of every member of the Home Guard, from the Commanding Officer and Senior Medical Officer down to the most recent volunteer, to our Canadian friends who, by the generous contribution of their time, their goods, and their money, have made possible this munificent gift, and all that it means to us both now and, perhaps even more, in the future.—I am, etc.,

London, W.1, Aug. 6.

A. LAWRENCE ABEL.

Treatment of Bacillary Dysentery

SIR,—Perusal of recent arrivals of medical journals (*Lancet* and *British Medical Journals*) reveals three communications in which bacillary dysentery is discussed, and which I feel called for comment. One is the annotation in the *Lancet* entitled “Chemotherapy inside the Bowel,” another Sir Philip Manson-Bahr's article “The Prevalent Diseases of Libya,” and the third Drs. Reitler and Marberg's “Note on the Treatment of Acute Bacillary Dysentery with Sulphapyridine” in the *British Medical Journal*. The first two are in some respects misleading, to my way of thinking, and the third requires to be seen in its proper perspective.

Sir Philip Manson-Bahr refers to bacillary dysentery as "this acute and often fatal disease," and proceeds to say: "It is to be hoped that lessons learned in the desert campaigns of the last war will not be overlooked in this—that bacillary dysentery (Shiga, Flexner, and Schmitz infections) will be readily recognized and promptly dealt with by well-accredited remedies." Practically the only accredited remedy he cites is anti-Shiga serum in Shiga infections, while he mentions as modern developments blood transfusions, and the use of "targesin" and of Moro's apple diet. But there is not one word about the most dramatic of all modern developments—phage therapy.

The theme in the annotation is the use of sulphanilamide preparations. Referring to sulphanilyl-guanidine, it is stated that "its most remarkable property is its bactericidal action on the coliform organisms in the mouse intestine." And passing from mice to man it is inferred that "if this activity extends to the intestinal pathogens the drug may prove most valuable in the treatment of infections localized mainly or entirely to the intestine, such as bacillary dysentery and cholera." All delightfully hypothetical! Further, there is the important admission contained in the two sentences: "Acetylation occurs, as with other members of the series, and the conjugated compound is probably concerned in the toxicity of the drug on the kidney. The authors believe from their tests that the toxicity of sulphanilyl-guanidine is of the same order as that of sulphyridine or sulphathiazole, and maintain that with reasonable care the risk of toxic effects will be small because so little of the drug is absorbed."

The third communication stands out quite apart as something concrete and helpful, being a record of results (twenty cases) with sulphyridine treatment, which the authors state to be "so uniformly good even in the severe cases" as to justify publication. The table accompanying the communication certainly tends to establish that sulphyridine can cure acute and chronic bacillary dysentery.

As a convinced adherent of phage therapy, a respect for the opinion of others and the good faith of all leads me to ask. Where does phage therapy really come in and why is it missing from these pictures? It can emphatically be stated that the treatment of acute bacillary dysentery presents no problem whatever provided one has at one's disposal good phage preparations and knows how to use them. That at least is my experience, and that of quite a number of medical practitioners in this city. Why under such circumstances, then, should valuable lives be lost or invalidated among our troops while the ideal sulphonamide derivative is being sought for (*vide* the annotation), although now possibly found (Reitler and Marberg's communication), when phage preparations rightly used can eliminate all this? Is it because experts at home and their representatives in military guise in the Near and Middle East remain unconvinced about the efficacy of phage therapy mainly because they believe it to be discredited? It is the easiest thing in the world to discredit phage. Bearing in mind its biological and conditional nature, it is easy to foresee that among other ways such a risk will be run whenever (1) the impossible is asked of it; (2) poor or ill-adapted phage preparations are used; and (3) nursing and diet are inadequately attended to.

For instance, it is unfair and rather asking the impossible of phage to expect it to cure other than the early acute case of bacillary dysentery, due to one or other of the classical or recognized organisms, since commercial dysentery phage preparations are prepared as a rule at the expense of classical organisms only. The concomitant organisms, which later often supplant the classical ones when the case has proceeded to gross ulceration and infection of the ulcers by secondary invaders, are not to any appreciable extent covered by many phages. To ensure the best results, phage preparations to cover such supplementary organisms should therefore be available if the case has proceeded at all beyond the initial stage. The simultaneous use, therefore, of phage preparations, based on a selection of representative bacterial substrates that are so far as possible 100% lysed *in vitro*, affords a chance of forestalling and dealing with virulent concomitants by direct lytic action (*d'Herelle*), by possible antiviral action (*Beředkal*), and by avirulent bacterial transformation action (*Compton*). That is what is meant by the note of warning about poor or ill-adapted phage preparations. Finally, by attention to nursing and diet

is meant that the acute patient should whenever possible be put to bed to reduce to a minimum his energy and food requirements; so that he can be put on a starvation diet of Vichy, Evian, or other mineral water for twenty-four hours to rest as much as possible the diseased bowel while the phage is carrying out its beneficial action (a 2-cm. ampoule of a good dysentery and meta-dysentery phage preparation, alternating with a like ampoule of a good *Salmonella* and coliform phage preparation every four hours during the first day; with a similar "follow-up" on the second day if required).

The paper by Reitler and Marberg is particularly interesting in that it appears to establish a future for the sulphonamides in bacillary dysentery. Their table of results seems to indicate for cases admitted to hospital on the first and second day of the disease, with treatment beginning on the second and third day, an average reduction in daily motions from twenty-two to six after twenty-four hours' treatment. With the perfected phage preparations now being employed by us we estimate a still more dramatic reduction, without any such qualification as "tenesmus . . . felt for one or two days more by some patients," as indicated by Reitler and Marberg. Tenesmus, in fact, is one of the first symptoms to disappear with phage treatment. This means that good phage preparations act more quickly and thoroughly than sulphyridine. Reitler and Marberg's figures suggest to me that the sulphonamides may find a useful place in the treatment of the chronic case (that may not respond immediately to phage), however satisfied they may at present be with sulphyridine in acute bacillary dysentery. In any case the introduction of sulphonamide therapy lends a reasonable hope to the emptying of wards of military hospitals which have hitherto been needlessly clogged with cases of dysentery because of no phage being available for immediate use at advanced field outposts, and which, I venture to suggest, might more rightly be labelled "neglected dysentery," with all that that may mean in a limitation of the suffering and invalidism from this often fatal disease.

Another advantage of phage therapy is that it is quite harmless, having no deleterious effect, so far as is known, on the kidney or other tissues, as may happen with sulphonamide therapy. In fact, this is one of the strange things about the phage lysis of toxic bacteria. After lysis the soluble lysates rich in bacterial disintegration products appear to be denuded of toxicity and can be injected intravenously with impunity. We at times utilize this property in these laboratories for the initial immunization of rabbits to obtain specific agglutinating serums when the antigens to be injected are at all toxic.

If the Service authorities have any doubt concerning the accuracy of the phage-therapy facts of this letter I am prepared, with the sanction of the Alexandria municipal authorities, to supply perfected phage preparations sufficient to treat twenty acute cases of bacillary dysentery, of not more than two to three days' duration from the onset of blood and mucus symptoms, in any military hospital in Alexandria, and can guarantee perfect results if the dietary instructions are adhered to during the two to three days of cure. With, I should hope, the return of the men to duty on the third or fourth day from the beginning of treatment.—I am, etc.,

ARTHUR COMPTON,
Director of Laboratories, Alexandria Municipality.

Unabsorbable Suture Materials

SIR.—A useful point to remember is that linen thread may be boiled in water which is alkaline without becoming rotten, whereas the slightest trace of alkali or even of alkaline earths rots silk with great rapidity. The late Sir Henry Gray habitually used linen thread for his operative work over a period of some twenty-five years with uniformly good results. He gave up using silk for the reason stated and for other reasons about the year 1912.—I am, etc.,

London, W.1, July 31.

Deaths on the Table

SIR.—The article on anaesthetics in your issue of August 9 (p. 207) is presumably written by the same gentleman who wrote the excellent letter which was printed in the *Journal* of June 7. This article on anaesthetics appears to be of paramount importance. I am not a professional anaesthetist, but I have given anaesthetics and have seen at close quarters very many given. At an operation I am, rightly or wrongly, always more interested in the anaesthetic than in the operation. I agree with Dr. Elam that some of those cases he mentioned could have been saved, and this applies probably to a good many other "deaths on the table." A case is made out for an immediate and close investigation into the subject of surgical anaesthesia. It is noticeable that in all the cases given by Dr. Elam gas-oxygen anaesthesia is involved. One is prompted to ask why the good old safe open-ether method is relegated to the hoary past to make way for a complicated engineering robot which, for all its battery of bottles and shining chromium, has not yet acquired all the virtues of a knight in shining armour.—I am, etc.,

London, N.W.11, Aug. 8.

L. S. WOOLF.

SIR.—The article on deaths on the table (August 9, p. 207) appears to be rather inadequate. After commenting on the possibilities of avoidance, your contributor then proceeds to give a somewhat confused account of a number of such deaths, with no attempt at differentiation between true anaesthetic deaths and those occurring while the patient is under the influence of an anaesthetic—a very different thing. Unless this is done it is impossible to get a clear view of what, after all, is the principal object—prevention. May I suggest that we should aim to have a clear view of the possible causes of death and a well-prepared plan of prevention, which should come into action at the earliest sign of impending collapse. I seem to remember that Hamilton Bailey emphasizes the necessity for such a plan in his excellent book *Emergency Surgery*.

Most anaesthetic deaths (including the examples given in your article) fall into one of three groups: (1) Deaths due principally or entirely to the anaesthetic. (2) Deaths incidental to anaesthesia—for example, vomiting. (3) Deaths due essentially to the patient's general condition or to the condition for which the patient is undergoing operation.

In Group 1 many deaths are unavoidable, but surely choice of anaesthetic, which calls for the fullest exercise of the anaesthetist's powers of judgment, could be the means of saving many lives. For example, in Case 6 quoted in Dr. Elam's article, the use of a local anaesthetic, which appears to be largely neglected in this country although widely used on the Continent, would seem to have been indicated. Again, correct premedication is of importance. Morphine, for instance, should usually be avoided, since by its depression of the respiratory centre it undoubtedly leads to unsatisfactory induction in many cases, particularly in the hands of inexperienced housemen. This may then be a factor in "ringing about a fatal issue, since there is a temptation to give larger doses of anaesthetic, although the real cause of the "lightness" is not lack of anaesthetic but shallowness of respiration.

In the second group deaths produced by vomiting, etc., can in some cases be prevented, as Dr. Elam points out, by pre-operative stomach washouts and the use of the most suitable means of anaesthesia.

It is in the third group—those cases in which the patient's general condition is adverse—that most can, and should, be done in the way of prophylactic treatment. Most of us now must have seen many air-raid victims who would never have survived successful surgery but for the efforts of the resuscitation squad. Surely the same principles of treatment should be applied to the civilian case. Pre-operative saline, plasma, or blood is frequently life-saving, and every anaesthetist should be able to direct administration before or during the operation. Such preventive treatment is physiological, and is calculated to meet with a greater measure of success than the tardy resort to stimulants, many of which have been shown, experimentally and in practice, to be of doubtful value.

As an example, may I be permitted to mention a patient who came under my care as resident surgical officer in an E.M.S. hospital. An aircraftman was admitted from an R.A.F. sick

bay with right pyonephrosis. The kidney was completely disorganized, and after chromocystoscopy had shown the contralateral kidney to be functioning satisfactorily, nephrectomy was decided upon. His general condition was poor, and before operation his temperature was 103° and his pulse 120. During the operation his condition rapidly deteriorated, and towards the end his pulse was imperceptible and his breathing shallow in the extreme. The wound was rapidly closed by through-and-through sutures, by which time breath sounds and movements could scarcely be detected and pulsation was absent everywhere in the systemic circulation. The apex beat was only just audible with the stethoscope, and the pupils were dilated and fixed. However, the administration of plasma was followed within twenty minutes by an almost miraculous recovery, and after a quantity of blood had also been given the patient was returned to the ward in excellent condition. But how much better it would have been had this collapse been prevented by the earlier administration of continuous physiological fluid!

Particularly in intestinal obstruction and urinary retention is an appreciation of the biochemical changes and their application to pre-operative treatment likely to repay the surgeon. In this group also come those cases where choice of a suitable operation may make all the difference to the patient's prospect of recovery. Included here are the rapid guillotine amputation, two-stage methods where feasible, etc.

It is a pleasure to me to record my thanks for permission to quote the case mentioned in this letter to Mr. Hugh Donovan and Mr. Dudley Marks, advisory surgeons to this hospital.—I am, etc.,

Aug. 11.

R.S.O., E.M.S. Hospital.

Ether Convulsions

SIR.—I would be grateful if you would permit me to comment on some of the statements put forward by Mr. Hamilton Bailey (July 5, p. 32). The fact that a cerebral depressant, such as evipan, is effective in ether convulsions and convulsions due to novocain does not imply, necessarily, a similar origin to these convulsions. Inadvertent intravenous injection of a local anaesthetic will tend to give rise to syncope or convulsions. Mr. Dickson Wright suggested nembutal in the treatment of ether convulsions some years ago. Evipan has been advocated by many observers.

In 1928 Dr. Hadfield noted that the heat factor appeared to occur in a number of cases of ether convulsions, but the significance of this, if any, was not stressed. I have elaborated on this factor in several papers, and suggested that "these cases may be due to the combination of toxæmia, dehydration, hypernæcæmia in a warm atmosphere, together with partial anoxæmia, difficult to avoid in anaesthesia, all tending to produce sufficient electrolytic imbalance to increase muscular and nervous excitability." Anoxæmia as a cause appears to have received special attention in American clinics, and a personal observation of cases deprived of oxygen would tend to make me appreciate the importance of this as a contributory factor.

I append a short bibliography which would apply more especially with regard to the points raised by Mr. Hamilton Bailey.—I am, etc.,

July 7.

Communal Feeding in Schools

SIR.—I see in the *Journal* (August 9, p. 211) that Dr. Letitia Fairfield advises the medical profession to "think twice before supporting a demand for communal meals as a normal thing for all children in peacetime," though she admits that "under the stress of war conditions school feeding has become a general necessity," and that "all would agree that it should be made an opportunity for teaching the value of good cooking, the wise selection of foods, and a civilized manner of life." Why, then,

does she virtually advise us to oppose communal feeding in schools in peacetime? The reasons Dr. Fairfield gives are approximately as follows:

1. She regards the taking of meals together as a strong binding element in family life, which she fears may be lost or weakened, together with parental authority and family discipline. If these fears were well founded one would expect to see the dire results of communal feeding on those who have "suffered" from it—namely, the children of the middle and upper classes, the majority of whom spend their most impressionable years in communal living at public schools. Yet the disastrous effects which Dr. Fairfield fears have never become manifest under the public school system, whose products are alleged to be the backbone of the nation.

2. She thinks our aim should be to help the mother in her task of feeding her children, but not to take it out of her hands altogether, which she fears would be the end-result. Why the end-result should be considered calamitous even if it came to pass is not clear. However, Dr. Fairfield agrees that the mother should be helped in her task of feeding her children, and I ask, In what better way can we help her and her children than by the provision of properly balanced school dinners? In this way we can make the best of both worlds, for "dad" and "mum" can still preside at breakfast and tea without loss of vitamins and the other essentials of a healthy diet so difficult to ensure when all the meals are taken at home. It is true that man does not live by vitamins alone, but it is also true that he cannot live without them, and suffers from a shortage of them and the other essentials of a properly balanced diet.

According to the figures given by the Chief Medical Officer of the Board of Education in his annual report for 1938, 11.3% of the school children seen in routine medical inspections were slightly undernourished, and as there is no reliable means of detecting undernourishment in its early stages or when the diet is not grossly deficient, the total number of undernourished school children may easily be 20% or more. Therefore the only real solution of this nutrition problem lies in compulsory and universal school dinners. It is too important for the nation as well as for the children to leave to chance any longer. Moreover, there is no reason why school dinners should appreciably increase the taxpayers' burdens, as the parents of all but necessitous cases should be required to pay the full cost, which would probably be considerably less than the cost for which they could provide a similar meal at home.—I am, etc.,

G. W. FLEMING,
Medical Officer of Health.

Gosport, Aug. 12.

Aggregation of Toddlers

SIR.—In Dr. James Kerr's letter in your issue of July 26 (p. 137) occurs the sentence: "Crèches and day nurseries should not be tolerated in any civilized communities . . . except under the inevitable compulsion of war." Since the extension of crèches and day nurseries is one of the urgent requests to local authorities made by the Ministry of Health at the present time, it might be of interest to consider the objections raised more closely, and to try to assess the experiences already gained in this field in peacetime conditions both in this country and in Soviet Russia, where the system has been widely used for many years.

Dr. Kerr appears to be in full support of nursery schools, which he believes to be "the right of every child from 2 to 5 years of age," and records the benefits of the system in the greater freedom from infections, debility, and accidents. Further, he stresses the biological necessity for plenty of space and freedom where children can be fed, exercised, sleep, grow, and educate themselves into the membership of a child community. His objections to crèches and day nurseries appear to be based on the greater risks of infection in younger children, but he points out, nevertheless, "that it is, however, the homes themselves which are the chief distributors of early infections." Further, he makes a plea for the early immunization (at 1 year) of children for diphtheria, which he regards as of much greater value than that of the school child. This surely is something which comes within the scope of the crèches and day nurseries, and could be extended to cover the risks of infection from whooping-cough and measles (pooled adult serum for prophylaxis). My own experience in peacetime crèches and day nurseries in Edinburgh, particularly in slum districts where large

families predominated, was consistently favourable, as evidenced by the improvement in height, weight, and physique of those children attending them. That the mothers were of like opinion was shown by the long waiting-lists for admission. These experiences are borne out by numerous other public health workers in different towns.

In Soviet Russia, where perhaps the majority of women prefer to continue their careers after marriage, the number of crèches and nursery schools is proportionately large—840,000 in urban areas in 1939 and a million in rural areas. These latter include the seasonal nurseries, and also the large caravans in charge of a trained nurse, with all the usual equipment, which follow the mothers out to the fields so that they may feed their babies at the appropriate times. A doctor and trained nurse are always attached to these crèches, and a routine examination of every child is made each morning on admission. Pulse and temperature are taken and the throat examined. In this way it is possible to prevent the outbreak of epidemics of colds, influenza, etc., as well as the more serious infections, and to maintain constant supervision of the health of every individual child. As a prophylactic measure against summer diarrhoea, etc., and tuberculosis many of the crèches and nursery schools move out of the large towns into the countryside for part of the summer. This measure has proved of considerable value in present circumstances, since children and mothers as well as staff have long been accustomed to the idea of evacuation to the countryside and seaside during the summer months. The success of day nurseries and crèches, as well as of nursery schools and kindergarten, is reflected in the health of the child population, the fall in the mortality and morbidity rates of infectious diseases, and in the rate of child mortality in the U.S.S.R., which has fallen by half since this policy was instituted in 1917.

In view of these experiences under peacetime conditions, both in this country and abroad, I believe it should be possible to view the extension of the crèche and day nursery system not as a necessary evil but as a useful and permanent contribution to child welfare and the gradual development of preventive medicine in this country.—I am, etc.,

Assistant M.O.H.

Southall, Aug. 17

Malnutrition

SIR.—What are we to think of Lord Woolton, who said breezily at Cheltenham last week that there was no malnutrition in this country? Careful investigations have found that one-third of the children born in this country are born into families that have not enough money to give them adequate food. A great social reformer has said that children are the greatest single cause of poverty in this country. Have our rulers not yet realized that it is self-satisfied short-sightedness of this sort (to call it by its most polite name) which caused Lord Baldwin to deceive himself and us when he said he was keeping our Air Force equal to that of Germany, and poor Mr. Chamberlain to trust in the mesmeric quality of his eye to force Hitler to keep the promises he gave him at Munich, when the latter had already broken all the promises he had made before then.

If there is no malnutrition, why do children from our big cities flourish so radiantly in the country after they have been there a few months? Why are our soldiers so undersized compared with the Australians? As doctors, we must never cease to din into the heads of our rulers that no family of five persons can be adequately nourished unless its gross income exceeds 60s. to 65s. per week. If to enter a State Medical Service is to be governed by such people as these rulers let us remain instead in our present muddle.—I am, etc.,

Colchester, Aug. 11.

M. E. LAMPARD.

Diet and Teeth

SIR.—In his letter to you of August 9 (p. 212) Mr. Griffith Evans asks: "Has calcium nothing to do with teeth?" Mr. He does not make it quite clear whether he is discussing the effect of calcium on the development of teeth or on the incidence of dental caries. As regards their development, Sim Wallis, Fish, and others have shown that only a diet with an extremely low calcium content will adversely affect tooth structure, for the developing teeth have a priority over the bones and other tissues

in receiving whatever calcium is contained in the diet; so that only in gross cases of rickets are rickety teeth to be found, and while no one imagines that the diet of the poorer classes is perfect to-day, cases of rickety teeth have been very infrequent for years.

Dental caries is a saprophytic phenomenon caused by the penetration of bacteria into morphological crevices and permeable enamel faults. These crevices and faults are common to all mammals, but caries is not, because the bacteria concerned occur to any great extent only in man. A hereditary factor appears to govern the depth of the crevices and the number and extent of the enamel faults, as caries-free teeth often run in families; such families are to be found in all classes irrespective of diet, hygiene, vitamins, sunshine, etc. Because of their shape, which does not easily lead to food lodgment, rickety teeth are often less prone to caries than teeth of a normal dentition. The other main factors controlling the incidence of dental caries are the amount and kind of carbohydrate food eaten because of its bacteria-culturing properties in the mouth, the efficiency of oral hygiene, and an immunity factor sometimes present apparently in the saliva.

Thus, unless the standard of national diet falls to a level that was found only among the very poor in the last century, then the national loaf will have nothing to do with teeth, and even if a generation grows up with rickety teeth it will probably have a lower incidence of dental caries than the present one.—I am, etc..

Berkhamsted, Aug. 9.

JAMES CAMPBELL.

Chronic Sick in Bombed Towns

SIR.—Sir Frederick Menzies has made an eloquent plea on behalf of the "chronic sick" patients in the institutions of our towns that have been subjected to enemy bombing, urging that prompt and energetic measures should be taken for their removal to places of greater safety. I wish to add a plea for the still larger numbers of "chronic sick" patients living in their own homes in those areas. Their danger may not be as great as that of those receiving institutional care, but they are subjected to unnecessary risks and to privations and discomforts due to war conditions. Early in the war you published a letter from me pointing out the fact that no special steps had been taken to minimize the risks they ran. At that time there were no A.R.P. shelters for those unable to make use of the Anderson or the public shelter; no hope of evacuation to safer areas; no respirators available for those unable to use the ordinary civilian one; no special rationing. Nor can we forget the coal muddle during the first severe winter, when many were without coal for several weeks and some were reduced to breaking up their scanty furniture to provide heat for cooking and for warmth. Not till eighteen months had passed was there any alleviation of their lot, and then only in a few directions. At the same time a word of praise is due to many of the air-raid wardens, who gave special care and encouragement to the crippled and bedridden during air raids.

Much still remains to be done before we can feel satisfied that the "chronic sick" are receiving the care that is their due. The general practitioner is, in the main, responsible for their medical care in their homes; war risks are the responsibility of the community, and in these cases of the local authority. A census of the "chronic sick" is needed first of all. As a matter of fact, where there is an efficient A.R.P. service the necessary data could no doubt be obtained from the air-raid wardens. Every individual patient should be visited and assured that his safety and comfort are not being neglected. Many of the sick poor live lonely lives, occupying a single room, often in an upper story, and steps should be taken to persuade them to remove to a room on the ground floor. The provision of indoor shelters for all such sick persons is essential, and where the patient has no friend to help him to get into his shelter during air-raid alarms a warden should be available to help him and to stand by and cheer him.

On no section of the community does the system of rationing bear more harshly than the sick poor; when the rations are obtainable only with difficulty the sick poor may have to go without their share, and they, for various reasons, are often unable to get a fair share of unrationed foods as well. Many of them suffer from impaired appetite and digestion, and it is most unfair that arrangements have not so far been made to increase the amount of some of their rations. I submit that special issues

of such articles as eggs, oranges, tomatoes, etc., should be made available to them as well as to children. For those, too, who are willing—though these are probably a minority—evacuation to a safer area where special care should be provided for their comfort is the best solution of the problem.—I am, etc.,

Manchester, Aug. 10

ARNOLD GREGORY.

Lectures on First Aid

SIR,—I have recently attended a lecture in a country district by a medical officer of the Ministry of Health on what was called "Wartime First Aid." The lecturer divided treatment into four parts—haemorrhage, asphyxia, unconsciousness, and fractures. The tourniquet was mentioned and condemned, compression of the femoral and subclavian arteries being advised. Apart from the difficulty of finding and compressing the femoral artery in a big muscular man, it will be impossible to compress it efficiently while the patient is being lifted on to the stretcher, conveyed to and carried in the ambulance, especially in the upper compartment, while on the stretcher with its slung bed, and finally taken out of the ambulance and carried along corridors to a ward. The same applies to compression of the subclavian, and rather more so, as the patient will be lying down. A rubber tube, or preferably a band three or four feet long, with tape at one end, is all that is required, and it is a pity that the Government cannot see its way to supply every air-raid warden and certain other A.R.P. personnel with one. It is not foolproof, but with proper instructions and careful watching it is the safest thing.

Splints came in for general dismissal, especially the long Liston. Possibly in large towns with many casualties there may be no time to splint a limb, but in scattered country districts the case is different. Fractured femurs, especially if compound, in dirty surroundings are major casualties, as was discovered rather late in the last war, and the mortality and morbidity from them until this was recognized were very considerable.

Shock was included under the head of unconsciousness, but shock should have been recognized and treated before unconsciousness arises, if it does at all; unconsciousness generally means something more serious than shock.

It is to be remembered that roads may be blocked by troops or craters, and cases may have to be brought across country, taking time and causing jolting, and there is no question that the "old-fashioned" methods, as the lecturer called them, of the British Red Cross and St. John will still be carried out and many lives saved thereby.—I am, etc.,

HOWARD M. STRATFORD, F.R.C.S. Edin.

Beckley, Sussex, Aug. 9.

Penetrating Wounds of the Abdomen

SIR,—Having had some experience of penetrating wounds of the abdomen, I was glad to see this straightforward report of a case published by Mr. Geoffrey Parker, though at the same time a little surprised that it should still be thought necessary to point to its lesson.

For the first ten months of the last war I was surgeon to a base hospital at the base in Mesopotamia, and owing to difficulties in transport we seldom got cases in hospital under three days from the time of their being wounded. Of the few abdominal cases we did get, all died (peritonitis, etc.) save one, and he had saved himself by developing a faecal fistula in the caecal region. All the others had died either early from shock or bleeding, or from peritonitis during transit to the base. None was operated on. I am told that something of the same sort has been happening in Africa. At the base hospital it was too late, and, moreover, we were still labouring under the old rule of "Leave 'em alone."

But towards the end of 1915, during the siege of Kut, I had the same equipment but was now in the "front line," and so was able to receive the wounded often within a few minutes of their being hit. Indeed, as soon as we realized the importance of early operation, special arrangements were made to get "abdominals" in quickly, which also gave one a chance of operating at once on some cases of progressive internal bleeding (of which the pulse is the best indicator) and ligaturing the torn mesenteric vessels, apart from the damage to the gut itself.

As regards the point under review, I soon came to realize the danger of abstaining from operating on cases where one could

not be certain that penetration had not occurred, for even the most innocent-looking entrance wounds, without exit wounds, might be accompanied by extensive damage to the gut, and I emphasized this in describing some cases.^{1,2} Fraser and Bates, Russell, Gordon-Taylor, and others have also stressed the danger of leaving such cases alone. Indeed, "when in doubt, do a splenotomy" should be an axiom of surgical practice with those who have to do with these cases.—I am, etc.,

C. H. BARBER,

Lieut.-Colonel I.M.S. (ret.).

Thame, Aug. 5.

Mechanism of Inflammation

SIR,—Your leader (March 1, p. 321) on factors that participate in the process of inflammation has led me to draw attention to the following unconsidered situations. When a tissue is injured, resulting in a haematoma without breach of the skin, a serum can be extracted which greatly promotes the extent of the growth and morphological robustness of bacteria cultured therein, such as streptococci. Serum extracted from a twenty-four- or forty-eight-hour-old haematoma produces this effect when added to tryptic broth or blood agar plates as compared with controls. It appears that the inflammatory lysis which is an essential antecedent to repair promotes a process of autodigestion in the tissues affected, which is, in effect, analogous to that technically adopted in the addition of trypsin to the protein of a broth culture.

Such is a brief for the earliest possible sterilization of wounds before they become homologous culture media. This appears also to account, in part, for the high resistance of immobilized limbs, in that absolute rest entails optimum apposition of the histological elements of wounded tissues. This, theoretically, provides against repeated acts of lysis, which are made necessary by new adjustments called forth by fortuitous movements. A rule might be promulgated that bacterial fixation in wounds is, for lytic reasons, proportional to the time lost in sterilization.

In regard to the determination of protective leucocytosis in wounds, globulin agencies used for promoting phagocytosis have proved in my hands to lead on local use in wounds to a gross leucocytic exudate. This may be associated with a surrounding areola of hyperaemia and turgescence, suggesting that this agent should be diluted with normal saline before application. If an antitoxic serum with polyvalent properties, such as diphtheritic serum, be mixed with the globulin the acute inflammatory reaction is lessened, but the phagocytic process is still active. These recommendations are advanced as of possible value in adjunctive treatment of wounds emerging from the present war. The method just described was first tested in intractable ulcers with heaped-up rims resulting from a mixed infection by haemolytic types of both staphylococci and streptococci. Where these ulcers were confluent or were delayed in healing by the poor "subsoil" over the tibia, healing did not occur until the above measures were adopted. The infection described was caused by multiple sand-fly bites, which were later further complicated by carelessness in washing a purulent eczema of a type regarded as incurable in dogs, and for which the latter have always to be shot.—I am, etc.,

Melbourne, May 25.

FRANK TRINCA.

Sulphapyridine in *Brucella abortus* Infection

SIR,—I think Dr. Whittingdale, in his treatment of a case of *Brucella abortus* infection with sulphapyridine, may be doomed to disappointment unless he takes the precaution of repeating the course of treatment, as described by Richardson (*Lancet*, 1938, 1, 495), after intervals of three and six weeks, in order to avoid relapses.—I am, etc.,

Wimfrith, Dorset, Aug. 10.

P. R. BOUCHER.

Sulphonamides and Sulphur

SIR,—The observations made by Dr. A. D. Hodges in your issue of July 26 (p. 139) are of considerable interest to those of us whose clinical observations have not lent support to the widely held views concerning the supposed association of sulphonamide cyanosis with salines or sulphur.

It might be pointed out that the administration of magnesium sulphate is not a means of giving sulphur, as Dr. Hodges appears to suppose, any more than can the phosphorus intake be increased by giving phosphates, glycerophosphates, or hypophosphites. If the administration of magnesium sulphate during sulphonamide therapy increases the incidence of sulphaemoglobinaemia, it must do so in some other way than acting as a source of sulphur, such as by hastening the passage of sulphur-containing foods along the alimentary tract before absorption of the amino-acids has taken place, and so resulting in an increased production of hydrogen sulphide in the gut from bacterial decomposition of the food proteins, where the more liquid contents may provide a more favourable medium for bacterial growth, as suggested by Archer and Discombe. The prohibition of eggs and onions during sulphonamide therapy is irrational, as it would seem doubtful if with normal digestion the production of hydrogen sulphide is decreased by their exclusion, and in any case other articles of diet contain as much sulphur as, or more than, an egg or two.

Sulphaemoglobinaemia is much less common during sulphanilamide treatment than is methaemoglobinaemia, and the latter is transient and may be prevented by the administration of methylene blue. With sulphapyridine and sulphathiazole sulphaemoglobinaemia is so rare that it can be ignored. Moreover, the exact nature of the association between sulphaemoglobinaemia or methaemoglobinaemia and cyanosis is obscure, and the apparent absence of both of these abnormal blood pigments in some cases of sulphonamide cyanosis has led to the view that the formation of a coloured pigment from the sulphonamide may be concerned. I suggest, therefore, that the question of salines and sulphur during sulphonamide treatment is of little importance, and, in fact, the cyanosis itself has received a degree of attention which is undeserved. It is unfortunate that the undue attention paid to cyanosis has been associated with inadequate realization of the importance of other aspects of sulphonamide toxicosis, such as the deposition of crystals in the urinary tract during therapy by sulphapyridine and sulphathiazole, and a fear of agranulocytosis resulting in suboptimum dosage of sulphonamides in the early stages of their administration, leading in many cases not to a lesser but to a greater danger of this form of blood dyscrasia.

In answer to Dr. Hodges's question, the formation of sulphaemoglobin has been studied both *in vivo* and *in vitro*, using, however, sulphur in an available form—that is, as the element or as a sulphide. Among other items which I feel are of practical importance in connexion with sulphonamide therapy are: (1) In proportion to body weight children tolerate sulphonamides better than adults. (2) Whereas all sulphonamides are specific for infections by the haemolytic streptococcus, sulphathiazole or sulphapyridine are the only effective drugs against the non-haemolytic streptococci. (3) Sulphathiazole frequently proves strongly active against staphylococci. My own experience, including experiments on myself, has been entirely consistent with a number of these views.—I am, etc.,

London, Aug. 11.

J. T. S. GIBSON.

Lack of Calcium

SIR,—With regard to the letter by Drs. Graham and Burrows (August 2, p. 176), I should like to point out that osteoporosis is generally considered to be due to a vitamin D deficiency. One of the cases reported by Meulengracht (*Acta med. scand.*, 1937, 92, 584) had actually had a satisfactory calcium intake. The history of these cases frequently reveals an unbalanced diet owing to some stunt dietetic regime. The fifteen to twenty million people who depend on the customary diet and whose calcium intake is supposed to be below requirements should show some "unsatisfactory condition of the bones."

In conclusion I should like to say that Major Lloyd George stated in Parliament on August 6, in reply to a query by Sir Ernest Graham-Little, that the fortified loaf does not contain added calcium. I hope the matter is now finally disposed of.—I am, etc.,

Liverpool, Aug. 5.

I. HARRIS.

SIR,—Dr. Harris in his recent letter defies anybody to produce evidence of calcium deficiency in adults. This is difficult, since minor deficiencies usually cause only slight disturbances, which usually pass unclassified.

During the past few months I have seen eight women in late pregnancy with varying degrees of oedema—five of legs and feet only, the other three more generalized. In all of these cases the blood pressure was normal or subnormal. In none of them was there any evidence of anaemia or of cardio-renal or venous damage or disturbance. Calcium with vitamin D was given by injection to three of them with a certain degree of improvement.

There have also been during the past few weeks quite a large number of patients attending surgery with severe reactions to insect bites—huge blisters and a great deal of swelling and inflammation. There may, of course, have been a particularly poisonous type of midge about, but calcium deficiency may also be a contributory cause. Unfortunately I have no scientific figures to back my contention.—I am, etc.,

London, S.W.16, Aug. 12.

HARRIS AVERY.

Thirst at Sea

SIR,—In Sir Leonard Rogers's letter (August 9, p. 211) there is an obvious fallacy in his suggestion that sea-water might be made potable by precipitating chlorides by chemical means. This would leave the "saline" content undiminished in terms of numbers of molecules present, and increased in terms of percentage of "saline" in solution. Thus, $\text{AgNO}_3 + \text{NaCl} = \text{AgCl} + \text{NaNO}_3$; or 59 grammes $\text{NaCl} = 85$ grammes NaNO_3 . That means that sea-water (approximately 3% NaCl) would now become 4.5% (approximately) NaNO_3 , and I submit that a solution of such strength might well be more harmful to the consumer than the original sea-water.

Nitrates of the alkalis in weak solution are well-known diuretics. Strong solutions of any salt irritate the gastro-intestinal tract, and Cushman (*Pharmacology and Therapeutics*, 1924, p. 300) has stated that this non-specific effect may be reinforced by some specific irritation in the case of nitrates, and that isotonic solutions of nitrates are but slowly absorbed by the bowel. A 4.5% solution of sodium nitrate would be even more slowly absorbed (if at all), and would likely produce nausea, vomiting, or diarrhoea, and thus inaugurate a vicious circle.

Mr. Biske's suggestion to use diluted sea-water to alleviate thirst is more worthy of experiment. But one could argue *a priori* that any addition of salt to the body (oral, rectal, etc.) would lead eventually in those deprived of water to an increased sensation of thirst, since this varies directly with the concentration of the blood. In haemorrhage, extensive burns, severe vomiting, cholera, etc., both salt and fluid are lost, and the rationale of the use of isotonic solutions is sound, as it is also in heat-stroke, where the body is deprived of much salt as well as fluid in sweat. There has been no loss of minerals in cases of thirst at sea unless these unfortunate people are adrift under a tropical sun.

The problem might be solved by the use of a copper or metal still, easily portable, and heated on the principle of a primus stove. The distress of the dry cracked mouth and tongue might be relieved temporarily by glycerin and lemon pastilles, but sugar-containing sweets should not be allowed.—I am, etc.,

Hull, Aug. 10.

R. HARDY.

Peripheral Nerve Injuries

SIR,—As you are no doubt aware the Ministry of Health has established three centres in England and two in Scotland for the investigation and treatment of patients suffering from peripheral nerve injuries: one of the centres is at the Wingfield-Morris Orthopaedic Hospital, Oxford.

Much useful information could be gained from the examination of men who sustained nerve injuries during the last war, but unfortunately the Ministry of Pensions has no separate list of these patients, and it is therefore impossible to get into direct touch with them. It is likely that many general practitioners have among their patients a few who have had nerve injuries. Would any doctor in the Oxford area who happens to come across such a case be kind enough to help us by asking the patient, should he be willing and able to spare the time, to attend here for examination? The best times for attendance are Monday and Tuesday afternoons. A small sum of money is available for paying travelling expenses.—I am, etc.,

Wingfield-Morris Orthopaedic
Hospital, Oxford, Aug. 12.

H. J. SEDDON.

Obituary

SIR ALFRED RICE-OXLEY, C.B.E., M.D.

Sir Alfred Rice-Oxley, who was formerly Physician-Ordinary to Princess Beatrice, died on August 10 at the age of 85.

Alfred James Rice-Oxley was educated at Doncaster Grammar School, Balliol College, Oxford, and the London Hospital. He qualified M.R.C.S. and L.S.A. in 1877, and in 1882 proceeded to the M.B. and the M.R.C.P. In 1881 he took the M.D. of Dublin University. At the London Hospital he gained scholarships in human anatomy and clinical medicine, and the gold medal in clinical medicine. After qualifying he was house-physician at the London Hospital and at the Radcliffe Infirmary. He was honorary medical director and acting physician to the Princess Beatrice Hospital for Wounded Officers and the Dorchester House Hospital for Wounded Officers; he was also physician to St. George's and St. James's Dispensary. Sir Alfred was a member of the Council of the British Medical Association from 1910 to 1912. Subsequently he served on the Central Ethical Committee and the Committee on Lunacy Law and Mental Disorder.

Among other public offices Sir Alfred was president of the West London Medico-Chirurgical Society, vice-chairman of the Princess Louise Kensington Hospital for Children, and chairman of the Society of Yorkshiresmen in London. He was a member of the Order of Isabella the Catholic, and in 1927 received the *Légion d'Honneur*. He was three times Mayor of Kensington, and in 1922 was knighted. Sir Alfred was especially well known for his municipal work: he was a J.P., a trustee of the Camden Charities, president of the Kensington Council of Social Services, and chairman of the Leighton House Society. In 1923 Lord Phillimore, on behalf of the Royal Borough, presented him with his portrait in recognition of his many public services.

Lady Rice-Oxley died in January of last year. There were four sons of the marriage, of whom the second, Dr. D. G. Rice-Oxley, is Surgeon-in-Ordinary to Princess Beatrice.

The following is an appreciation from a former colleague:

Alfred Rice-Oxley practised for so many years in Kensington, and was so prominent in local government affairs there, that few now remember that he originally began practice across the river—I think in Clapham or Wandsworth. For all his long experience of public affairs, he retained a certain appearance of diffidence in putting forward his views, both in public and in private; this was probably due not so much to indecision or woolly thinking as to innate courtesy towards other people, though it did give the impression sometimes that he hardly knew his own mind. He had great sympathy with, and a benevolent disposition to, his younger colleagues in practice; and he was often known to offer words of encouragement just when they were most needed. Mayor of the Royal Borough of Kensington for three years (1919-22), he remained a valued member of the Public Health and Maternity Committee there long after he could well have pleaded that he was due for a respite. The list of his public activities is indeed a lengthy one, and it may safely be said that few members of the profession have done so much in local politics and at the same time made so few enemies. He was not a fluent, nor even a good, speaker; but always created conviction of his complete honesty and disinterestedness among his hearers—no slight matter when political feelings ran

high, though as a rule he steered as clear as he could of controversial topics. He was very proud of his Yorkshire origin and ancestry, and especially of Doncaster, where he had his boyhood's education. No account of his career would be complete without mention of the mutual devotion of Sir Alfred and his wife, who died only a year and a half ago after well over fifty years of happy married life. She helped him in his public duties as well as in private life, with a gracious presence and personality which Kensingtonians were not slow to recognize and appreciate.

JOHN MORGAN O'MEARA, M.D.

We regret to record the sudden death on August 10 at Luton, from cerebral haemorrhage, of Dr. J. M. O'Meara. He was 59 years of age.

John Morgan O'Meara was born in Lincolnshire, and received his medical education at University College, qualifying M.B., B.S. in 1905 and proceeding to the M.D. of London University three years later. After holding house appointments at Wolverhampton General Hospital and Tottenham Hospital he started in general practice at Luton, where he was soon joined in partnership by his brother, Dr. Hubert O'Meara. During the war of 1914-18 Dr. O'Meara volunteered for service in the R.A.M.C.(T.). He served in France, Gallipoli, Egypt, and Palestine until the end of the war, and returned home with materially impaired health from which he never fully recovered. He acted for many years as honorary medical officer on the staff of the Bute Hospital, Luton, and was secretary to the Medical Advisory Committee of the hospital. He relinquished this post when he was appointed in 1932 part-time medical officer to what is now known as St. Mary's Hospital. Nearly two hundred in-patients came under his care, and they now became the chief interest in his life. He gave devoted service to the care of these people, among whom there were many old, infirm, and acutely ill. He became a member of the British Medical Association in 1910, and was a regular attendant at divisional and branch meetings. He served on the Bedfordshire Panel Committee from its inception until the time of his death.

Outside his professional career Dr. O'Meara's chief interest was centred in cricket. At one time he played in a local team; he was an authority on the rules of the game and assisted in coaching the Luton Modern School, at whose first-eleven matches he was invariably present. He was a bachelor, and his life was devoted to his patients, who will miss him greatly. He was in harness to the end, being actually out on his professional rounds a few hours before his death.

W. PARRY MORGAN, M.D.

V. Z. C. writes: The late Dr. William Parry Morgan was a man whose modest and retiring disposition tended to prevent the immediate recognition of his many talents. He had an expert knowledge of mathematics and physics, which, at an early stage in his medical career, helped him to devise an improved apparatus for inducing artificial pneumothorax and led him to conclude that it was safe to induce bilateral partial pneumothorax. His work in proving the possibility and safety of this latter procedure did not at first gain immediate acceptance, and now that the technique is well established it is only just that Parry Morgan's pioneer work should be recognized. He was very fond of music, and although almost entirely self-taught was no mean performer on the piano. He was conscientious almost to a fault, was endowed with a fine sense of humour, always proved himself a faithful friend, and was generally beloved.

[An obituary notice of Dr. W. Parry Morgan was published in the issue of July 12.]

SIR FREDERIC STILL

Dr. E. BAINES writes: I only noticed yesterday the obituary notice of Sir Frederic Still. I thought it was most sympathetically done and gave a great idea of the man. Two points which may seem unimportant, but which, to my mind, marked the man, were that he went to Caius hoping to start natural science at once, and was deeply disappointed that, having taken a scholarship in classics, he was required to take a classical degree. Undaunted, he worked at classics and took a first class in his tripos. Then he took a second course and came out in the first class for his natural science.

Dr. MUNGO BRYSON, who died in an Edinburgh nursing home on July 14, had practised for many years at Thornhill, Dumfriesshire. He studied medicine at the University of Glasgow, graduating M.B., C.M. in 1890. At Thornhill he was physician to the district isolation hospital and medical officer to various institutions, including the Scottish Education Department and the Post Office. He had been secretary of the Panel Committee for Dumfriesshire, and in 1924-5 held office in the British Medical Association as president of the Border Counties Branch.

Dr. JOHN ANDERSON SMITH, for fifty-four years a member of the British Medical Association, died on July 16. He had long practised at Willesden Lane, Brondesbury, N.W. Born at Hull in 1862, and educated at Rossall and St. Bartholomew's, Dr. Anderson Smith took the M.R.C.S. and graduated M.B.Lond. (with honours in obstetric medicine) in 1886, proceeding to the M.D. two years later. His early appointments were those of house-physician at the Brompton and the City Road Hospitals, and in 1887 he was appointed surgical and medical registrar at the North-West London Hospital. He was for many years district medical officer to the Metropolitan Water Board, honorary medical officer to the Kilburn and St. John's Wood Dispensary and Edgar Lee Home for Cardiac Diseases, and a member of the medical staff of the Willesden Cottage Hospital and of St. Monica's Home.

Dr. HUGH CAMPBELL FERGUSON, who died on July 28 at Wimbledon, realized in many years of active and successful work his early ambition to serve his profession and the community in the general practice of medicine. Graduating M.B., Ch.B. (with commendation) in 1899 at the University of Glasgow, he proceeded to the M.D. degree in 1903. In the interval he devoted himself to a long course of clinical and pathological study at the Glasgow Royal Infirmary and at the Sussex County Asylum, in both of which institutions he held resident posts. Thereafter his professional record is one of general practice in South London and Wimbledon, and in this he found both an opportunity for service and an instrument of self-development and education. To his professional equipment he added the personal qualities which invite and retain confidence—thoroughness, efficiency, kindness, interest, and good will. Never of robust physique—for the last four years he had suffered from an incurable illness—he was yet capable of much hard work, and he well merited the trust and affection of those who looked to him for help and guidance. He had been chairman of the medical recruiting board, but failing health compelled him last March to relinquish duties which he had carried out with great tact and efficiency. To his colleagues Ferguson cultivated the loyalty and generosity which accord with the best traditions of the profession, and his intimate friends knew him as a man and a brother with a kindly, humorous, and philosophic outlook on life and affairs: he appreciated good talk and made his contribution to it. At home he enjoyed a true comradeship and valued this highly in his life and work. He is survived by his widow, his son, who is a member of the profession, and a married daughter.

We regret to announce the death on July 28 of Dr. FRANCIS GEORGE DOBSON, D.S.O., medical officer of health for Beverley Rural District Council. Dr. Dobson qualified M.B., Ch.B. at Leeds University in 1906, and was for a time house-surgeon and also anaesthetist at the General Infirmary at Leeds. During the last war he was officer commanding the 1/2nd W.R. Field Ambulance, B.E.F., and held the rank of lieutenant-colonel, R.A.M.C. He had been medical inspector of school children.

under the Leeds Education Committee, and at the time of his death was honorary medical officer to Beverley Cottage Hospital. Dr. Dobson was the son of the late Dr. Joseph Dobson, who practised in the Burley district of Leeds for many years.

We regret to record the death on July 31, as the result of an accident, of Dr. WILLIAM MURDIE of Wark-on-Tyne. He was the son of the late Mr. Alexander and Mrs. Murdie of Stronch-rubie, Sutherlandshire, and was educated at the University of Edinburgh, where he graduated M.B., Ch.B. in 1907. He was medical officer and public vaccinator for the 5th District, Bellingham, and medical officer to the Post Office. His contributions to medical literature included papers on vaccines in general practice (jointly), observations on infection by bacillus of tubercle (jointly), and a case of camphor poisoning, all of which were published in the *Medical Press and Circular*. He had been a member of the British Medical Association since 1922.

We regret to announce the death on August 1 of Dr. FRANK HAYDON in his eightieth year. He received his medical education at Westminster Hospital, and qualified L.R.C.P. in 1891. He specialized in ophthalmology and for five years was assistant surgeon at the Westminster Hospital; he had held the posts of clinical assistant at the Royal London Ophthalmic Hospital and ophthalmic surgeon to King Edward's Schools. For a time he was secretary to the Court of Examiners of the Society of Apothecaries of London, and for forty-five years he was oculist to the Southern Railway. Dr. Haydon was the author of several books, including an *Ophthalmic Atlas for Recording Pathological Conditions of the Fundus by Means of Superimposed Layers of Colour*, *Statistical Eyesight Tables*, and *Railway Test Type Case*. He had been a member of the British Medical Association for forty years.

Dr. HORACE SILVA DRABBLE, who died suddenly on August 4, was educated at Wesley College, Sheffield, and the University of Sheffield; he qualified M.R.C.S., L.R.C.P. in 1921 and started practice in that city. Later he became interested in anaesthetics, and was made honorary anaesthetist to the Royal Hospital, Sheffield, where he gave many years' devoted service. He took the D.A. in 1936. Dr. Drabble was an unusually competent anaesthetist, and was very popular with all his surgical and medical colleagues, as well as with the students under his supervision. He was a very likeable man with a charming personality. A keen golfer, he was one of the oldest members of the Hallows Club. When war broke out in 1914, although only 18 at the time, he enlisted as a private in the Sheffield City Battalion, and later was given a commission and went to France as a combatant officer with the rank of lieutenant in the York and Lancaster Regiment. The sudden death of his father late in 1936 came as a great shock, and precipitated a nervous upset which necessitated a rest from work for some time. He returned to practice, however, and, so far as any of his friends knew, was in the best of health and spirits just before his death. He will be deeply missed by a large circle of friends. He had been a member of the British Medical Association for thirteen years.

We regret to record the death at the age of 75 of Dr. WILLIAM MACCALL BOYD, at Largs, Ayrshire, on August 5. Dr. Boyd qualified M.B., C.M. at Glasgow in 1890, and joined the British Medical Association in 1894. He is survived by his wife, one daughter, and two sons.

Dr. SAMUEL LYLE, C.B.E., whose death took place on August 6 at Stockton-on-Tees, had been in practice in the town for thirty-nine years. Dr. Lyle, who was a native of Northern Ireland, graduated M.B., Ch.B. at Edinburgh University in 1901. During the last war he served with the R.A.M.C. in Gallipoli and Bulgaria, and in this country at the Military Hospital, Grantham. He was Ministry of Pensions Commissioner, East Central Region, and for his work in this capacity was awarded the C.B.E. He was honorary surgeon to Stockton and Thornaby Hospital from 1913 to 1930, and from then until his death was honorary consultant surgeon to that hospital. A keen member of the British Medical Association, he took a great interest in the work of the local Division. He had been a member of the Local Medical War Committee since it was first formed.

Lyle took an active part in the civic life of Stockton, and he was a Justice of the Peace from 1930. He was always interested in the local cricket and football clubs, and was well known in racing circles in the North-East, being chairman of the Stockton Race Committee. By the death of Dr. Lyle, Stockton loses a medical practitioner of sound judgment, a genial personality, and a true sportsman.

Dr. SPENCER VERDON-ROE died suddenly after an operation on August 7. Spencer Verdon-Roe was educated at Cambridge and St. Bartholomew's Hospital, qualified M.R.C.S., L.R.C.P. in 1897, and took the M.B., B.Ch. in 1898. After qualifying he was house-surgeon to the Radcliffe Infirmary, Oxford, and clinical assistant in the department of diseases of the throat, St. Bartholomew's, and in the ophthalmology department of the West London Hospital. He was subsequently assistant school medical officer in the L.C.C.

Miss MARY CAMPRELL HORNER, whose death at Limavady, Co. Derry, was recently announced, was educated at Queen Margaret College, Glasgow, and took the Scottish triple qualification in 1894. Medical missionary work became her life interest, for she served for thirty-one years in the Church of Scotland Mission Hospital at Mukden, Manchuria, before retiring in 1927. She initiated and built up, with Dr. Ethel L. Starmer, the women's hospital, the maternity school, and the babies' home, institutions which reflected her successful work on behalf of Chinese women and children and missionary workers.

Dr. JOHN TOPHAM SPINK, who died recently at Harrogate, was for many years a general practitioner at Otley. He was a student of the Yorkshire College at Leeds, and, after clinical training at the General Infirmary at Leeds, obtained the Scottish triple qualification in 1892. Dr. Spink was for a considerable time medical officer to the Child Welfare Centre at Otley. He was one of the oldest members of the Royal Wharfedale Lodge of Freemasons, in which he held office as Worshipful Master in 1902-3. He had been a member of the British Medical Association for forty-two years.

The following well-known medical men have died abroad: Dr. ALBERT GRAEME MITCHELL, professor of paediatrics at the University of Cincinnati College of Medicine since 1924, co-author with Dr. J. P. Crozer Griffith of *Textbook of Diseases of Infants and Children*, aged 52; and Dr. JULIUS FRIEDENWALD, emeritus professor of gastro-enterology at the Medical School of the University of Maryland, aged 74.

Universities and Colleges

UNIVERSITY OF OXFORD

At a Congregation held on July 26 the following degrees were conferred:

D.M.—A. H. Hunt.

M.Ch.—H. Rees.

B.M.—A. P. D. Montgomery, *R. F. G. Barker, F. G. Beilby, A. G. A. Albers, J. V. S. A. Davies, J. W. Gerrard, J. P. M. Tizard, C. G. Whiteside, *A. J. Wilmot, H. W. Davies, R. T. Campbell, L. T. Scott, J. F. Monk, R. H. Percival, *J. R. Tiller, Pamela M. Blake.

* In absentia.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

At an ordinary meeting of the Council of the Royal College of Surgeons of England, held on July 31, with Sir Alfred Webb-Johnson, President, in the chair, Prof. Alexander Primrose was appointed representative of the College at the centenary celebrations of Queen's University, Kingston, Ontario, and Surgeon Rear-Admiral G. Gordon-Taylor was appointed delegate of the College to attend the thirty-first Annual Clinical Congress in Boston, U.S.A., as the guest of the American College of Surgeons.

Diplomas of Membership were granted, jointly with the Royal College of Physicians of London, to the candidates whose names appeared in last week's issue in the report of the meeting of the Royal College of Physicians of London.

Diplomas in Ophthalmic Medicine and Surgery (nine) and in Medical Radiology (three) were granted, jointly with the Royal College of Physicians of London, to the candidates whose names appeared in last week's issue in the report of the meeting of the Royal College of Physicians of London.

The Services

COLONEL COMMANDANT, R.A.M.C.

Lieut.-General Sir J. A. Hartigan, K.C.B., C.M.G., D.S.O., retired pay, late R.A.M.C., has been appointed Colonel Commandant, from August 8, 1941, in succession to Lieut.-General Sir H. B. Fawcett, K.C.B., C.M.G., D.S.O., D.C.L., retired pay, late R.A.M.C., who has relinquished the appointment on account of ill-health.

R.A.F. AWARD

The King of Yugoslavia has conferred the Order of the White Eagle, 5th Class, on Flight Lieut. William Patrick Griffin, R.A.F.O., in recognition of valuable services rendered in connexion with the war.

MENTIONS IN DISPATCHES

The following have been mentioned in dispatches: Temporary Surgeon Lieut. H. A. D. Doyle, R.N.V.R. (H.M.S. *Ladybird*), for courage and devotion to duty during operations in the Mediterranean, and Temporary Surgeon Lieut. M. G. Low, R.N.V.R., for good services in the successful raid on the Lofoten Islands.

CASUALTIES IN THE MEDICAL SERVICES

ROYAL ARMY MEDICAL CORPS

Wounded

Captain John Hortas Jackson.
Captain Bethel Lapedus.
Captain Robert Norman Seed.

DEATHS IN THE SERVICES

Colonel LANCELOT PAXTON MORE, R.A.M.C. (ret.), died in a London nursing home on July 19, aged 72. He was born at Rothwell, Northants, on March 20, 1869, and was educated at the University of Edinburgh, where he graduated M.B., C.M., in 1891, serving as assistant demonstrator of pathology. Entering the Army as surgeon lieutenant in 1892, he became lieutenant-colonel in 1915, brevet colonel in 1917, colonel in 1918, and retired in 1922, having been on half-pay from April to October, 1920, on account of ill-health. He served on the North-West Frontier of India in the campaign of 1897-8, receiving the Frontier medal with a clasp, also the clasp for the Tirah campaign. He had been a member of the British Medical Association for twenty-four years.

Colonel ARTHUR HUGH MORRIS, C.I.E., C.B.E., R.A.M.C. (ret.), died at Boscombe on July 6, aged 69. He was born on February 26, 1872, received his medical education at St. Bartholomew's Hospital, qualified M.R.C.S., L.R.C.P. in 1894, and took the D.P.H. in 1905. Entering the Army as surgeon lieutenant in 1896, he became lieutenant-colonel in 1915, and retired as colonel in 1922. He served in British Somaliland in 1903, in the hospital ship *Hardinge*, receiving the medal with a clasp, and in the war of 1914-18, when he was mentioned in dispatches, receiving the C.B.E.; and in Mesopotamia from 1919 to 1921, receiving the C.I.E. He had been a member of the British Medical Association for twenty-four years.

Lieut.-Colonel CHARLES EDWARD WILLIAMS, I.M.S. (ret.), died at Farnham, Surrey, on July 28, aged 75. He was born on November 1, 1865, and was educated at the University of Cambridge, where he graduated M.B., B.Chir. in 1890. Entering the I.M.S. as surgeon lieutenant in 1893, he became lieutenant-colonel after twenty years' service, and retired in 1923. He served in the North-West Frontier campaign of 1897-8 and received the Frontier medal with two clasps. Most of his service was spent in Burma, where he was appointed a civil surgeon in 1896. He was appointed Sanitary Commissioner in 1898, and held that post until his retirement. He was a member of the British Medical Association for twenty years and was a member of the Central Council in 1904-5.

Dr. J. J. Bittner of the Roscoe B. Jackson Memorial Laboratory, Bar Harbor, Maine, U.S.A., has been awarded the Alvarenga Prize for 1941 for his studies on cancer. This prize is given each year by the College of Physicians of Philadelphia on the anniversary of the death of Pedro Francisco DeCosta Alvarenga, who died on July 14, 1883, and under whose will the prize was established, to the author of the work in any branch of medicine which is thought most deserving of the award.

Medical Notes in Parliament

Parliamentary Medical Committee

At a meeting of the Parliamentary Medical Committee last month, with Sir FRANCIS FREMANTLE in the chair, Lieut.-Colonel W. S. C. COPEMAN, in an address on rehabilitation, spoke of the work done in the Army in respect of both medical and surgical cases in shortening the period of treatment and convalescence and in counting the treatment as effective only in its single direction throughout to early future efficiency for service. He indicated, further, the application of the same change of view and practice to civil life, especially after the war, and showed the great economy, comfort, confidence, and welfare, individual and general, that should result.

Tuberculosis

Invited by Mr. RHYS DAVIES on August 6 to give statistics showing the increase or decrease in tuberculosis in England and Wales respectively for each quarter since the beginning of 1938, Mr. BROWN replied on August 7 that quarterly statistics were not available. The following table indicated the total numbers of new cases notified to local authorities or which came to notice otherwise than by formal notification during each of the three years 1938 to 1940.

	1938		1939		1940	
	Pulmonary	Non-pulmonary	Pulmonary	Non-pulmonary	Pulmonary	Non-pulmonary
England	40,109	13,759	37,697	12,233	39,363	11,335
Wales	3,096	1,129	2,943	1,000	3,184	1,047

On August 7 Mr. JAMES GRIFFITHS asked if Mr. Brown's attention had been called to the report of the Welsh National Memorial Association, indicating a deficiency of 400 beds for waiting tuberculosis cases in the Principality. Mr. BROWN replied that the Press reported that a statement was made at a recent meeting of the Welsh National Memorial Association to this effect. The question of increasing the number of beds at present available in Wales and elsewhere was under active consideration in the Ministry of Health.

Medical History of Recruits

Mr. BEVIN told Mr. Rhys Davies on August 7 that he had considered the suggestion that approved societies should be asked to supply medical boards with the medical history of men tested for service in the Army. This would not supplement the information already obtained to an extent sufficient to counterbalance administrative difficulties in its adoption. Every man was informed that the board would give careful consideration to medical evidence regarding any serious illnesses or disabilities, and was also asked to complete a questionnaire. Mr. Bevin added that, having administered an approved society, he would not place much reliance on the medical histories which such societies possessed. Arrangements had been made for notification to the medical boards of every man of military age whose name appeared on the register kept under the Public Health (Tuberculosis) Regulations. Every man examined was asked whether he had ever suffered from tuberculosis or received treatment for it or for suspected disease. Where there was reason to suspect tuberculosis the board referred the man for radiological or other special examination by the tuberculosis officer of the area in which he lived. The Medical Advisory Committee under Lord Horder had decided that it was impracticable for the chest of every recruit to be radiologically examined. Equipment and personnel to examine the results were not forthcoming.

British Dispensary at Hankow—On July 29, Mr. Law informed Mr. Nunn that the British Dispensary at Hankow ceased business last April owing to difficulties arising out of the closure of the Yangtze. Special efforts to help this British firm were made by the British Consuls at Hankow and Shanghai, and some shipments of medical supplies were permitted to Hankow for the dispensary. Owing, however, to great delays and to the fact that no miscellaneous goods were allowed to be shipped, the turnover became insufficient to keep the firm in business.

Condition of School Milk.—Mr. LEACH raised, on July 31, the question of the condition of milk delivered to Southport schools. He said a report of the Southport Health Department indicated that one sample of milk must have been stale before it was pasteurized. Mr. BUTLER replied that the Department of Education had communicated with the Ministry of Food, which had taken up the matter. The conditions prescribed for pasteurized milk included a bacterial standard for the milk after, but not before, pasteurization.

Grant for Soldiers' Wives during Pregnancy.—On August 5 Mr. TOM SMITH asked the Secretary of State for War whether he was aware that cases were arising of wives of Service men continuing to go out to work while in an advanced state of pregnancy in order to supplement their separation allowance; and whether he would consider the desirability of making an additional allowance of 10s. a week to all such cases on the production of a medical certificate and on the condition that the woman refrained from going out to work for a specified period. Captain MARGESSON said he was unable to accept the suggestion for a flat increase of 10s. a week in such cases, but any case in which serious hardship arose would be considered on its merits by the Ministry of Pensions with a view to the award of a war service grant of up to £2 a week. If serving in the United Kingdom the soldier should himself make an application for such a grant through his commanding officer. If he was serving abroad the application might be made by his wife through the regimental paymaster or the nearest office of the Assistance Board.

Diabetics' Food.—Major Lloyd George is advised that no further concession is necessary at present in the diet of diabetics.

Medical News

Mr. E. Rock Carling and Prof. S. P. Bedson have been elected members of the Medical Research Council in place of Prof. G. E. Gask and Prof. W. W. C. Topley, F.R.S.

The name of Dr. Wilfrid Boothby Blandy, firewatcher, Nottingham, has been brought to notice for brave conduct in civil defence.

The seventieth annual meeting of the American Public Health Association will be held at Atlantic City from October 14 to 17. Further information can be obtained from the headquarters of the association at 1790 Broadway, New York City.

The Swedish International Press Bureau reports that a board for the control of incorrect or misleading advertisements of medical preparations has recently been founded, consisting of representatives of the Royal Medical Board of Sweden, the Swedish Medical Association, the Federation of Swedish Industries, the Advertising Association, and the Newspaper Publishers' Association.

In view of the difficulty in wartime of maintaining or replacing the plant required for pasteurizing milk by the "Holder" process, the only process hitherto recognized under the various milk Regulations, licences are to be granted for "high temperature short time" pasteurization. It is understood, states a Ministry of Health circular (No. 2423), that provided the apparatus is suitable and is worked with proper care, this method will effectively destroy any disease-producing organisms in milk. The chief modifications are that the milk must be kept at a temperature of not less than 162° F. for at least fifteen seconds, and that there must be an automatic device on the apparatus to divert the flow of any milk which has not been so treated. Local authorities may obtain advice about any proposed apparatus from the National Institute for Research in Dairying, Shinfield, near Reading.

Although the money collected by the British Red Cross Society and St. John Fund has now reached a total of some £6,500,000, five-sixths of this has already been spent, and an additional £1,500,000 is necessary if the Fund is to meet the ever-growing demands that are made upon it. It is therefore proposed to develop the penny-a-week scheme, which has been so successful in organized industry, by house-to-house collections throughout the country. In an appeal for active help from women in carrying out this new scheme, the Duke of Gloucester pointed out that there were ten million houses in this country, and if only one occupant in each gave a penny a week the Fund would benefit by a further £2,000,000 a year.

Private generosity and the enterprise of the Royal Sussex Hospital, Brighton, have combined to provide what amounts to domiciliary massage and electrical treatment for those patients of the hospital who, because of physical infirmity or the expense of the journey, are unable to attend at the hospital. A motor-van equipped with all the apparatus necessary for electrical treatment, with the exception, owing to the war, of portable diathermy apparatus, has been presented to the hospital by Mrs. Herbert Latilla (founder of the Latilla Department of Physical Medicine) and her two daughters. This van, which is staffed by masseuses from the hospital department and driven by members of the W.V.S., is in daily use for visits to country districts. The hospital authorities have provided that to avoid overlapping and abuse of the service all new patients shall, in the first instance, attend at the hospital and pass through the almoner's department.

Eight residential nurseries for children who have suffered in air attack have already been established in various parts of Britain through the generosity of the Save the Children Federation of New York, and allowances have been made to some 80,000 similar children. Mr. Henry J. Allen, a former governor of Kansas, and chairman of the British Children's Aid Committee, who has been on a visit to this country, hopes to extend the help now being given, and, by increasing by another £175,000 the £75,000 already contributed, to provide at least 100 additional nurseries, where children may have a permanent home and medical treatment when necessary. It is also hoped to endow a training school for matrons and superintendents.

As promised in Circular 2395 (*Journal*, June 28, p. 979), the Ministry of Health has issued further information about the Fracture Clinics "C," which are being established under the Emergency Hospital Scheme for the out-patient treatment of fracture cases. The Ministry now states in Circular 2395A that certain hospitals are to function as Fracture Clinics "C," as well as special clinics which are to be recognized for the purpose. The arrangements for the latter are not yet complete, but the Ministry has issued a list of the hospitals within the Emergency Hospital Scheme which are to be Fracture Clinics "C." The list, which is attached to the circular, has been sent to local authorities and their medical officers of health and to all voluntary hospitals in the scheme. It is pointed out that hospitals designated as Fracture Clinics "C" should claim for the treatment of fracture cases in the same way as they claim for out-patient treatment of any other cases under the Emergency Hospital Scheme.

On production of a certificate from the doctor or midwife who has been booked to attend a confinement, or, in the case of a woman attending an ante-natal clinic, from the medical officer of health, expectant mothers will be supplied by welfare authorities with fifty coupons to buy materials for garments which should be made before the baby is born. The certificate, which should be given as soon as the diagnosis is made (usually the sixth month of pregnancy), should state the mother's name and address, her National Registration number, and the approximate date on which the confinement is expected. Double the number of coupons will be issued where a positive diagnosis of twins has been made and confirmed.

In memory of the late Sir Frederick Grant Banting a maple tree was planted on May 1 in mingled soil from several Canadian hospitals in the grounds of the Richmond Memorial Hospital, Prince Bay, Staten Island, as a part of National Hospital Day ceremonies.

According to the *Dagens Nyheter* of Stockholm one hundred cases of typhus are registered in Warsaw monthly. All of them are in the Ghetto.

Dr. Eugene M. K. Geiling, professor of pharmacology at the University of Chicago, recently received the Mendel medal of Villanova College "for his articles on the knowledge of the pituitary gland, its relations to other glands, and for his assistance in the crystallization of insulin."

The Rumanian Government has announced that the gas-masks which it is distributing free to the population are not for Jews. Should any be left over after distribution to the non-Jews the Jews may buy them at a fixed price.

The June issue of the *Annals of Internal Medicine* contains an interesting article by Dr. Thomas Parran, Surgeon-General of the United States Public Health Service, entitled "Medicine in England Now," in which he states that "we doctors in the United States should be inspired by the example of our British medical colleagues."

It has been announced that eye-shields used for industrial or A.R.P. purposes are not subject to purchase tax.

The German academy for naval doctors, which had been moved from Kiel to Danzig, has again been moved to Tubingen until its building in Danzig is ready.

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended July 26.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included), (b) London (administrative county), (c) Scotland, (d) Eire, (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease are for: (a) The 126 great towns in England and Wales (including London), (b) London (administrative county), (c) The 16 principal towns in Scotland, (d) The 13 principal towns in Eire, (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

EPIDEMIOLOGICAL NOTES

Infectious Diseases for the Week

Acute poliomyelitis, dysentery, and scarlet fever have all increased in incidence during the week; that of the enteric fevers and cerebrospinal fever has declined. In Scotland a like trend has been observed, except that scarlet fever also has declined.

Acute Poliomyelitis

Since the previous week notifications of poliomyelitis have risen from 10 to 29, and the number of administrative health areas involved in England and Wales has risen from nine to sixteen. In the Slough area, although only 7 cases fall within this week's return, reports have been received that there have been 12 confirmed cases in addition to the 9 already recorded. Of these new cases 7 are in Slough itself and 5 in Eton Rural District. As regards age, 2 patients are under school age, 8 are school children, and 2 are older, one of whom is 30 years of age. The new cases have appeared in five other schools in the district. Avoidance of travelling and meeting in public places, and the use of gargles, are suggested by the public health authorities as the best means of checking further spread. Details of the incidence and distribution of the cases notified are: Buckinghamshire 7 (Slough M.B. 3, Eton R.D. 4); Radnor 3 (Presteign U.D. 1, Rhayader R.D. 2); Lancaster 2, in Manchester and in Denton U.D.; Lincoln Kesteven 2, in Grantham M.B. and in Stamford M.B.; Lincoln Lindsay 2, in Lincoln City and in Gainsborough U.D.; Stafford 2, in Stoke-on-Trent C.B.; and 1 each in Berkshire (Maidenhead M.B.), Durham (Whickham), Hertford (Hertford M.B.), Kent (Bromley M.B.), Middlesex (Staines), Norfolk (Blofield and Felgg R.D.), Oxford (Oxford C.B.), Shropshire (Shrewsbury M.B.), Yorkshire, East Riding (Kingston-upon-Hull C.B.), Yorkshire, North Riding (Stokesley R.D.), and Yorkshire, West Riding (Leeds). In Scotland cases occurred in the counties of Aberdeen 1, Ayr 2, and Stirling 1, and in the burghs of Kirkcaldy, Glasgow, and Edinburgh, 1 each.

Dysentery and Paratyphoid Fevers

Although nearly one-half of the total notified in the week occurred in one district, the number of areas affected by dysentery has risen from eleven to twenty-two; in only four were single cases recorded. The areas reporting more than 4 cases were as follows: Brecknock 69, all in Brecknock M.B.; Lancaster 23 (Blackburn C.B. 1, and R.D. 10. Whiston R.D. 5, Warrington R.D. 2, Southport 2, Manchester 1, Lancaster M.B. 1, Preston R.D. 1); Essex 7; and Surrey, Yorkshire, West Riding, and Durham 5 each. The disease is relatively more common in Scotland, involving ten areas, notably the counties of Lanark 26, Aberdeen 4, Clackmannan 4, Kincardine 2, and Orkney 4 (return for preceding week included), and the burghs of Dundee 10, Glasgow 3, Aberdeen and Edinburgh 2 each, and Airdrie 1.

More than one-half of the cases of paratyphoid fever in the whole country were recorded in Lancaster, 133; of the twenty-seven other counties affected, only seven recorded more than 4 cases—namely, Chester 43, Northumberland 10, Glamorgan 10, Warwick 8, Northampton 7, Yorks, West Riding, 6, Stafford 5. In Scotland eleven areas were affected, in five of which a single case occurred; there were 10 cases in Glasgow, and in Dundee 9, Stirling 2, and in the counties of Lanark 3, Angus 2, and Ayr 2.

QUERIES AND ANSWERS

Tests for Glycosuria

E. A. d'A. writes: Is there any exact method known for testing the urine for sugar which needs no heating and yet is accurate enough that a negative result excludes with certainty the presence of any reducing substance, and thus glucose?

Income Tax

Change in Partnership: Cash Basis

A and B are in partnership, A taking two-thirds and B one-third of the cash receipts. As from April, 1940, the shares became equal, but any debts outstanding at April, 1940, were divided in the old proportion. How should the assessment for 1940-1, which is on an earnings basis, be divided between the partners?

* * On the basis applicable to 1940-1—that is, one-half each. The fact that A may be receiving cash to a greater extent is not material. Those receipts are the ingathering of earnings of years the income of which has already been assessed. It is true that the assessments for those years did not specifically take those receipts into their calculation, but their absence was compensated for by other receipts, the fundamental assumption being that at that time gross cash receipts and gross earnings were about equivalent.

Keep of Assistant—Assessability

"H. P. N.'s" firm employs an assistant on terms that he shall receive £420 per annum and all found. The firm pays £3 3s. a week to the lady with whom he boards. Is tax payable by the assistant on this £3 3s. a week?

* * It is common ground that if the assistant's board and lodging were provided by one of the partners it would not be assessable, and we do not see why a distinction should be made because that accommodation is provided elsewhere and at a definite, and not an estimated, cost. We assume that the liability to pay the £3 3s. is on the firm and not on the assistant; if, on the other hand, the assistant has in law made a contract with her, so that the partners are discharging his liability, then we fear that money so paid can be regarded as paid to the assistant, and we could not advise an appeal on these special facts. If the contract is between the firm and the landlady, we advise the assistant to appeal, though it might be well as a preliminary to put the facts before the Board of Inland Revenue, Somerset House, W.C.2.

Whole-time E.M.S. Appointment

N. W." points out that the assessment of an E.M.S. salary as a separate item of income may involve payment of tax on the earnings as a whole at an excessive figure.

* * The illustration suggested is a case where the amount of the 1939 earnings, and therefore of the 1940-1 assessment, was £1,500, and the E.M.S. salary of £550 began as from April 5, 1940. In such a case the earned income will be assessed at £1,500 (Schedule D) plus (three-quarters of £550) £412 (Schedule E)—an aggregate of £1,912. If for the year to April 5, 1941, the practice earnings to which "N. W." is entitled fall by £383 or more, then his actual aggregate earned income will be less than the amount assessed by more than one-fifth, and in that case he will be entitled to have the assessments reduced to the "actual" amounts. There will be no hardship, but, on the other hand, a probable ultimate gain when he resumes his practice work and benefits under the previous year's

rule of assessment. But that depends on the actual figures, and the reduction may not be enough to enable the claim for the "actual" year's basis to be made, and it is suggested that in such circumstances it should be permissible to treat the E.M.S. salary as part of the practice income. Unfortunately that is not legally correct, and the Inland Revenue Department are very unlikely to concede the point. It will be appreciated that the one-fifth test is of general application and has statutory force, and any departure from the correct legal position would create difficulties—for example, as regards R.A.M.C. pay.

Assessment of Property

E. F. W. has been assessed in respect of his house on £122 for War Damage contribution and income tax, Schedule A. The property is rated at £117.

* * Normally the gross value of property is the same for taxation as for rates, but a difference arises in the net value owing to the fact that the deduction made for upkeep is not always calculated at the same percentage of the gross value. In any case the taxation authorities are not bound by the rating valuation.

LETTERS, NOTES, ETC.

Corneal Ulcers cured by Sulphapyridine

Dr. SYDNEY TIBBLES (London) writes: In May last I was asked to see a woman aged 60 who was suffering from recurrent corneal ulcers of her right eye, which was intensely inflamed as she had in addition keratitis and an iridocyclitis. As we could discover no reason for these latter complications the ulcers were twice cauterized with carbolic and she was put on atropine drops, a perchloride lotion, and a mercury and iodide mixture internally. As the ulcers recurred the lids were painted with silver nitrate, but no progress was made in spite of all treatment, so she was put on sulphapyridine, one tablet thrice daily, and immediately responded. Ten days afterwards the vision was 6/12 with that eye, which was perfectly normal except for a slight scarring due to the ulcers.

Attending a Colleague

Mr. W. McADAM ECCLES, M.S., F.R.C.S., writes: In reference to the correspondence relating to the above it may be stated that there is in existence already, and has been for many years, all the machinery necessary for carrying out "payment to specialists" for treatment of professional colleagues. It exists in the British Provident Association, and all interested—and it should be the whole profession—may write to the Manager, B.P.A., 30, Lancaster Gate, London, W.2, for full particulars.

Accommodation for Doctor's Family

Dr. "A. B." whose family have been evacuated from London, offers accommodation free of charge to a family, preferably medical, who would attend to his own domestic needs. Letters addressed to Dr. "A. B." c/o the Editor, will be forwarded.

Shortage of Glucose Preparations

Dr. J. J. BROWN (Hackney, E.9) writes: The difficulty and in some areas the apparent impossibility of obtaining sufficient quantities of glucose preparations, especially in pleasant liquid form, is presenting medical practitioners with an awkward problem. Is the shortage due to transport difficulties, or is it because glucose is rationed to the makers of these very useful products? In either case a serious effort should be made to ease the situation. Glucose finds numerous applications, and in many circumstances there is no satisfactory substitute.

First Aid for Horn-rimmed Spectacles

Dr. K. E. D. DAUNCEY (Yeovil) writes: At the present time it is difficult to get repairs to horn-rimmed spectacles carried out without considerable delay. There is an effective and easy method of temporary repair which can be made by anyone at the cost of a farthing by using half a length of ordinary cycle valve rubber. The break usually occurs near the centre of the bridge, but the same method can be used for the sides. The edges of the break should be moistened and then the rubber pushed on, one end on one side and then the other end on the other. Care must be taken that when finished the fractured ends are in apposition. The splinting is not rigid, but is hardly noticeable and is comfortable in wear. The rubber perishes after about three weeks, but it can easily be replaced should the new spectacles be delayed longer than that time.

CLINICAL OBSERVATIONS ON AIR-RAID CASUALTIES

BY

R. T. GRANT, M.D., F.R.S., and E. B. REEVE, B.M., M.R.C.P.

The Clinical Research Unit, Guy's Hospital

The following paper contains the substance of a report prepared for the Medical Research Council's Committee on Traumatic Shock. It is based on 100 cases, 41 of them from the series observed at this hospital and 59* from case records supplied to us by the committee. Observations have not been confined to air-raid casualties, but have also been made on other cases of injury. Accident cases display the same varied features as air-raid casualties; they have the advantage that their observation is easier, since they are not as a rule admitted in large numbers in a short time and since the disturbing features of a bomb attack are absent. We have omitted cases of the so-called crush syndrome and of severe burns, which are being dealt with by others.

With these exceptions, and according to our own experience of many more cases than are here dealt with, this series illustrates the variety of the general reactions to injury shown by air-raid casualties and accident cases. The series, however, is not a random sample. The case reports received from the Committee on Traumatic Shock record for the most part examples of multiple and severe injuries associated with a low blood pressure and receiving transfusion for resuscitation. Our own cases were chosen in the first instance from those described by our colleagues as being "shocked" on admission, and later because they presented features of interest apart from a diagnosis of "shock," though this was applied to the great majority.

General Features

Some of the general features of the cases are summarized in the accompanying table. They are divided into three main groups, according to the level of systolic blood pressure when they first came under observation: in most cases this happened within a short time after admission to hospital; in few was it delayed more than an hour. The groups are those with (I) a raised systolic pressure, over 140 mm. Hg (9 cases); (II) normal pressure, 100 to 140 (28 cases); and (III) low pressure, under 100 (63 cases). The group with

Table showing General Features of the Cases

		I	II	IIIA	IIIB	IIIC	
		Low Blood Pressure (under 100 mm. Hg.)					
		Raised Blood Pressure (over 140 mm. Hg.)	Normal Blood Pressure (100 to 140 mm. Hg.)	Slow Pulse (under 70 per min.)	Moderate Pulse (70 to 100 per min.)	Rapid Pulse (over 100 per min.)	
Totals		9	28	9	27	27	Tot
Age in years	10 to 19	1	6	1	3	3	12

	" 72 "	1	1	1	1	1	3
	3 days or more	7	18	1	9	3	38
Deaths	Within 24 hours	1	1	1	10	13	27
	" 48 "	1	1	1	4	4	11
	" 72 "	1	1	1	1	1	3
	After 3 days or more	1	12	1	1	1	3

low pressure is subdivided according to the initial pulse rate: (A) slow, under 70 beats a minute (9 cases); (B) moderate, 70 to 100 (27 cases); and (C) rapid, over 100 (27 cases). It will be seen that this classification, originally adopted for convenience, serves to separate the cases into groups differing in certain other respects also; but we regard it as provisional only, and seek a better.

The series includes persons of all ages from 8 to 71, 30 being females. About one-third of them are under 30 and one-third over 50. It is of interest to note that of the 37 patients with initially raised or normal pressure (Groups I and II) only 8 (22%) are aged 50 and over, while they number 25 (40%) of the 63 cases with low pressures (Group III). Again, of those with low pressures, 7 of the 9 with slow pulses (Group IIIA) are aged 50 and over, but only 3 of the 27 with pulse rates over 100 are of this age (Group IIIC). These findings suggest that in injured subjects the

* For these records thanks are due to:

Army Blood Transfusion Service, 19 cases
Dr. Helen Brown, N.W. London Blood Supply Depot, 8 cases
Dr. J. McMichael, British Postgraduate Medical School, 7 cases
Dr. James Dow, St. George's Hospital, 5 cases
Dr. P. W. Mollison and Dr. Van der Walt, S.W. London Blood Supply Depot, 5 cases
Dr. T. S. Gavey, Westminster Hospital, 4 cases
Dr. R. F. Ball, Royal Free Hospital, 2 cases
Prof. W. Wilson, Aberdeen University, 2 cases
Mr. J. Ledingham (student), Hackney Hospital, 2 cases
Dr. G. A. R. Miles, St. Thomas's Hospital, 1 case
Dr. J. K. Denham, Western Fever Hospital, 1 case
Dr. R. D. Blachford, Charing Cross Hospital, 1 case
Dr. C. Wilson, Billericay Hospital, 1 case
Dr. E. E. Pochin, University College Hospital, 1 case

Thanks are also due to all those at our own and other hospitals whose co-operation made these observations possible.

HERPES LABIALIS AFTER SULPHAPYRIDINE AND T.A.B. THERAPY

BY

C. E. VAN ROOYEN, M.D.

Major, R.A.M.C.; Pathologist at a Military Hospital

A. J. RHODES, M.B., Ch.B., M.R.C.P.Ed.

Lecturer, Department of Bacteriology, Edinburgh University

AND

A. CAMERON EWING, M.B., Ch.B.

Captain, R.A.M.C.; Venereologist at a Military Hospital

Although herpes labialis is clinically a harmless infection its causal agent has been the subject of much research. The condition is often seen in soldiers, and a Swiss regimental physician (Mayer, 1921) has described a spontaneous outbreak of 30 cases among 70 soldiers who slept in one barrack-room. Five of the 6 officers attached to the same unit were also involved. Last winter we observed 33 cases among hospital patients and investigated them from the laboratory point of view. Two classes of persons suffering from herpetic eruptions were studied—namely, normal healthy nursing orderlies, who developed it spontaneously, and a larger group comprising patients treated for gonorrhoea.

Before beginning our description of the clinical-pathological findings and animal inoculation results we should like to present a summary of modern conceptions regarding the aetiology and pathogenesis of herpes. The disease was first proved to be infective by Vidal (1873), and thereafter the classical researches of Levaditi, Doerr, and others showed that the causal agent was a filterable virus which was highly pathogenic to the rabbit, and which produced violent keratitis if implanted upon the scarified cornea of that animal, occasionally followed by meningitis and death. Individual strains of virus differed in their neurotropic affinities for the rabbit; consequently attention turned to herpes simplex virus as being a possible cause of encephalitis lethargica, and Levaditi and Harvier (1920) claimed to have isolated the virus from such cases. Unfortunately, independent confirmation of Levaditi's researches was lacking and the work fell into disfavour, but it may still prove that his investigations were made in advance of the times. The clinical nomenclature employed for the designation of the various manifestations of herpetic infection in man is unsatisfactory. Thus the usage of terms such as "herpes simplex," "febrilis," "labialis," "recurrent herpes," and "idiopathic and symptomatic herpes" indicates that the classification is inconsistent, and not based on anatomical, clinical, or aetiological grounds. For the convenience of readers over-seas the following account contains a summary of the facts respecting the clinical types of herpes and their aetiology. At the outset it should be understood that all forms of herpes affecting man, *other than herpes zoster*, are due to one and the same virus, which is pathogenic to the rabbit, whereas the virus of herpes zoster is a separate entity which is non-pathogenic to the rabbit and probably related to the virus of varicella. Both herpes and zoster viruses are particulate and visible organisms which occur in the form of minute virus elementary bodies, and Elford *et al.* (1933) have succeeded in measuring herpes simplex virus, estimating it to be 100 to 150 m μ in diameter. Herpes virus also produces specific histological changes, and acidophilic intranuclear inclusion bodies have been described in human corneal epithelium (Fuchs, 1933) and in the large epithelial cells present in human vesicle fluid (Da Fano, 1923).

Clinical Varieties of Herpes

Herpetic infection may appear in a variety of forms, as follows:

Herpes febrilis is the term applied to herpes arising during the course of a pyrexial disease, such as pneumonia, malaria, influenza, and other febrile disorders. The usual situation is on the lip, the term "herpes labialis" then being popularly used; but when other areas of the face are involved it is called "herpes facialis." Aphthous stomatitis is another disease which has been proved to be due to the herpes virus (Dodd, Johnston, and Buddingh, 1938; see also Gottron, 1938; Burnet and Lush, 1939). Herpetic vesicles are seldom bigger than a large pin-head and develop on a reddened base, being usually filled with clear fluid, although suppuration may occur. The commonest site for vesicles is on the lips, inside and around the mouth, the cheeks, and the auricles.

Herpes simplex is the designation applied to herpetic eruptions, unassociated with pyrexia, which may arise spontaneously, or secondarily to a variety of causes, such as after the injection of vaccines, milk, and colloidal metals (see Fischer, 1927); or the ingestion of certain foodstuffs followed by gastric disorder.

Herpes Genitalis.—Herpetic eruptions are not uncommon on the genitals, being found on the glans or body of the penis, and, in the female, on the labia. It is frequently associated with syphilis (Cranston Low, 1939).

Herpes Cornealis.—Herpetic infection of the cornea may assume a variety of forms, of which the dendritic ulcer is the best known (see Duke-Elder, 1938). The inflammatory reaction may be severe and result in serious scarring of the cornea.

Recurrent Herpes.—Certain persons are very susceptible to herpes, and why this should be is not clear. It is possible that they carry the virus in their saliva or elsewhere in the body, and Burnet and Lush (1939) have suggested that in such instances the infection is contracted in infancy, as an aphthous stomatitis, and persists throughout life. Some particular recurring susceptibility of the tissues may allow the virus to exert its pathogenic action from time to time, and, for instance, recurring genital herpes is apt to occur in cases of irritation due to chronic gleet and prostatitis (Avit-Scott, 1931). In women recurrent herpes is often associated with the menstrual period (Blum, 1926). Apart from the question of variations in the host as the predisposing factor in recurrent herpes, it is possible that the strain of virus itself may possess unusual tenacity. Thus Nicolau and Banciu (1924) inoculated a number of persons with strains of virus from cases of recurrent infection and found that two of these persons themselves developed recurrent herpes.

Nervous Manifestations.—Although herpes is usually regarded as a mild local lesion, more serious manifestations may arise from time to time. For example, French authors (e.g., Levaditi, 1922, 1926) describe *herpès névralgique de Mauriac*, with symptoms of severe pains, crises of hyperaesthesia in the perineum, tenesmus, sphincter spasm, and sciatica, all preceding the appearance of the eruption. In less severe cases herpes may be accompanied by pruritus, backache, and neuralgia. Doubtless these are due to the fact that the virus involves the corresponding ganglia, producing an inflammatory reaction (see Howard, 1905).

Herpetic meningitis is a distinct clinical entity, with sudden onset, rapid course, favourable outlook, and a lymphocytosis in the cerebrospinal fluid (see Abiteboul, 1936).

The Common Aetiology of Herpetic Eruptions

To-day all herpetic eruptions (always excepting, of course, those of zoster) are regarded as due to one and the same virus, based on the following evidence:

Vesicle fluid from all varieties of herpetic eruption can be inoculated into the human skin, with consequent production of a typical crop of "simplex" vesicles (Vidal, 1873; Lipschütz, 1921b; Teissier *et al.*, 1922b; Frei, 1931; Zurukzoglu and Hruszek, 1933).

Vesicle fluid from herpes febrilis produces a severe keratitis when applied to the rabbit's eye (Löwenstein, 1919, 1920; Grüter, 1920). Herpes cornaealis yields a virus with the same characteristic effect (Doerr, 1920; Doerr and Vöchting, 1920; Luger and Lauda, 1921).

Herpes labialis yields the same virus, and will produce typical herpes cornaealis when suitably applied to the human cornea (Doerr, 1920; Doerr and Vöchting, 1920; Fuchs, 1921, and see Fuchs, 1933).

Vesicle fluid from herpes genitalis also produces keratitis in the rabbit, and man can be reinfected with material taken therefrom (Fontana, 1921; Blanc and Caminopetros, 1921).

Herpes occurring in such diseases as cerebrospinal meningitis, pneumonia, diphtheria, influenza, catarrhal jaundice, erythema, and secondary syphilis yields a virus showing the same characteristics as does that obtained from cases of primary herpes (Teissier *et al.*, 1922a).

Similar intranuclear inclusion bodies have been reported in human herpes febrilis, cornaealis, and genitalis, and in experimental lesions in animals (Lipschütz, 1921a, 1921b, 1921c; see Fuchs, 1933).

Distribution of Virus in Infected and Healthy Persons

Herpetic Vesicle.—The virus is abundantly present in the vesicular stage, but disappears after the crust forms (Teissier, Gastinel, and Reilly, 1926a).

Blood.—The agent may be found in the blood of persons suffering from herpetic eruptions, although this is rare (Löwenstein, 1919; Bastai and Busacca, 1924b; Teissier, Gastinel, and Reilly, 1926a, 1926b).

Cerebrospinal Fluid.—Flexner and Amoss (1925a) examined the cerebrospinal fluid of 100 persons, including some suffering from epidemic encephalitis, but in only one case were they able to isolate herpes virus, and this from a syphilitic patient with no herpetic eruption. This is an important observation, and indicates that the virus may, although rarely, be found in the cerebrospinal fluid of patients who at the moment do not suffer from herpes. Zurukzoglu (1937) has also isolated two strains of herpes virus from the cerebrospinal fluid of healthy persons. With regard to the cerebrospinal fluid of herpetic patients, the consensus of opinion is that the virus may be found on occasions (Ravaut and Rabeau, 1921; Bastai and Busacca, 1924a; Zurukzoglu, 1937), but a number of competent investigators have been unable to detect it (for example, Doerr and Zdansky, 1924; Levaditi, 1925; Teissier, Gastinel, and Reilly, 1926a, 1926b).

Saliva.—Herpes virus has been found in the healthy saliva by a number of workers (for example, Levaditi, Harvier, and Nicolau, 1921; Doerr and Schnabel, 1921; Teissier, Gastinel, and Reilly, 1926b). The virus is attached to the salivary epithelial cells and is probably associated with the buccal mucus, because suspensions of salivary gland tissue are avirulent (Levaditi, Harvier, and Nicolau, 1921). The presence of the virus has usually been detected by its ability to produce keratitis in rabbits. Levaditi and his collaborators have stated that 80% of normal specimens of saliva produce experimental keratitis, but only in 15% is keratitis severe enough to be followed by cerebral involvement (see below). These high figures have not, however, been generally accepted by other workers, who

have failed to find any virus in normal saliva (for example, Flexner and Amoss, 1925b). Nevertheless there seems no doubt that the virus can on occasion be found in this site, as described below. Several workers have investigated the saliva of persons suffering from herpes and have, though rarely, been successful in demonstrating the presence of the virus (for example, Isaicu and Telia, 1922; Flexner and Amoss, 1925b; Nicolau and Poincloux, 1922, 1924). Thus it has been found in the saliva of patients suffering from labial and facial herpes and herpes of the finger. The saliva of persons predisposed to herpetic eruptions contains the virus more often than that of other persons, and it may be found in the intervals between attacks (Levaditi, 1926).

Conjunctival Sac.—The virus can apparently be carried in a latent form in the conjunctival sac, but if the cornea be injured it may produce keratitis (Grüter, 1924; Busacca, 1925). It may also cause severe unilateral conjunctivitis, developing without obvious reason (Granström, 1937).

Other Skin Lesions.—The agent of herpes has been recovered on rare occasions from zoster vesicles and sycosis pustules (Naegeli and Zurukzoglu, 1935).

Our present article deals with the condition of herpes labialis which developed in healthy (often perfectly fit) male adults or, as in the majority of our cases, in patients under treatment for gonorrhoea. Below we describe our own work, which is subdivided into clinical data, laboratory findings, and animal inoculation experiments (performed by Dr. Rhodes), followed by a discussion on the aetiology of the condition.

The Present Research: Clinical Data

Altogether 33 cases of herpes labialis were studied by us: 6 occurred spontaneously in healthy nursing orderlies and 27 in patients suffering from gonorrhoea who had received a full course of sulphapyridine and subsequently developed herpes labialis after a provocative dose of T.A.B. The dosage of sulphapyridine administered was that employed before the latest Army instructions, and consisted of 9 grammes on the first day, 6 on the second and third, and 4 on the fourth, the total quantity given being 25 grammes in four days. The clinical results of such therapy were excellent, and in the majority of instances the urethral discharge had abated by the fifth day, so that on the sixth day patients underwent a test of cure consisting of a 0.2 c.cm. dose of T.A.B. vaccine injected intravenously. It was following this provocative dose of T.A.B. that herpes frequently manifested itself. In the first batch of subjects 22 patients received 0.2 c.cm. of T.A.B. vaccine intravenously, and forty-eight hours later it was noticed that all the men developed herpes labialis. Sixteen showed only a slight eruption, which cleared up spontaneously without any treatment: but in the remaining 6 the lesions were severe, and a 50% absolute alcohol dressing was applied with good effects.

Following these results Captain J. A. Scott, R.A.M.C., decided to reduce the dose of vaccine, and the next batch of 6 cases received 0.1 c.cm. of T.A.B. intravenously. Once again herpes was observed, and 3 persons were affected. Subsequently one of us (A. C. E.) decided to dispense with intravenous T.A.B. as a provocative measure, and thereafter hypertonic saline solution (instilled and retained in the urethra for a short time) was substituted as an alternative, following which no further cases of herpes appeared. The obvious conclusion to be drawn from such results is that if herpes labialis is to be avoided, intravenous T.A.B. vaccine should not be given to persons immediately after they have received a course of sulphapyridine. This is particularly so during the winter months, when, as we shall mention later, the herpes carrier rate is relatively high.

A CASE OF PUERPERAL TETANUS

BY

BRUCE MACLEAN, M.D., M.R.C.P.

Honorary Physician and Honorary Assistant Neurologist

AND

P. CHALLEN, M.R.C.S., L.R.C.P.

*Senior House-physician**North Staffordshire Royal Infirmary*

Cases of tetanus occurring in the mother following child-birth have been recorded in many parts of the world, but after careful study of the literature at our disposal we are unable to find any reference to such in the British Isles. Obstetrical textbooks discuss the possibility of its arising from imperfectly sterilized catgut used in suturing lacerations, and of tetanus neonatorum from infection of the umbilical cord. Because of the above facts we consider the following case should be recorded.

References in the Literature

We find that post-partum tetanus has been described mainly in America, France, China, and Germany. Some interesting points might be cited from various articles.

Milnor (1928) states that tetanus is prevalent in the Hawaiian Islands, and, though difficult to assess, he estimates the mortality to be in the region of 92%. Most cases arise from puncture of the skin, and a few from operative abdominal wounds, but puerperal tetanus is uncommon. He records two cases affecting both mother and infant in which there were no recoveries. Mattison and Starkey (1931) state that tetanus following induced abortion is very rare in America. The mortality is high—91% according to statistics compiled by Schneider. They record the case of a white woman aged 33 who developed tetanus fourteen days after induced abortion and three days after having a splinter in her finger. They consider the abortion the likely aetiological factor, taking into account the shortness of the incubation period from the injury to the finger and the fact that the latter showed no inflammatory reaction. The woman recovered, following treatment with antitetanic serum, 272,000 units being used in ten days by all routes—intrathecally, intravenously, and intramuscularly.

Byrne (1928) describes a case of puerperal tetanus, and states that he could find no record of a similar one in the district of Loyuan, although he knows it to be common in other parts of China. Knight (1933), referring to the appalling hygienic conditions in India attendant on childbirth, remarks that tetanus is a notable complication; the former he attributes to religious custom and superstition, and he recommends the use of patience, tact, and kindness in circumventing the latter. He considers "that the marvel is not that so many die, but that so many live under this Spartan treatment! It is truly a case of survival of the fittest." Rossi (1936) states that tetanus neonatorum is a frequent complication in Dakar, but reports only two cases of tetanus in the mother. Houël, Lesini, and Morand (1928) describe two cases of post-partum tetanus, one having generalized spasms, the other localized spasms confined to the jaw and the cervical and dorsal spine muscles.

Case History

A woman aged 25 was admitted to the North Staffordshire Royal Infirmary on October 16, 1940, complaining of spasms of the masticatory muscles and aching of the neck and back muscles. Fifteen days previously she had been delivered of a normal baby by forceps, and the perineum had been repaired with fine silkworm-gut sutures. Five days before admission she noticed stiffness of her jaw muscles, with the onset later of definite spasms which gradually increased in severity. On October 15 aching of her neck and back muscles began. The patient could not recall any recent trauma, and she was obviously a woman who took good care of her person.

The patient was well nourished and of healthy appearance, and she was obviously in pain. It was impossible for her

to open her mouth more than a quarter to half an inch; her tongue was swollen and discoloured, and her speech slurred. The masseters were in tonic contraction, entering at intervals into severe spasm of variable duration. She was found to have cervical rigidity.

Central Nervous System.—Cranial nerves: Nothing abnormal discovered. Limbs: Motor and sensory responses normal, but all reflexes exaggerated; muscle tone not abnormal, plantar responses flexor. Abdominal reflexes were not elicited.

Cardiovascular System.—Pulse: Good volume and tensile regular; rate 90, rising to 130 during the paroxysmal spasms. Heart: Normal position and sounds.

Respiratory System.—Lungs: No impairment of percussion note; broncho-vesicular breath sounds; no adventitious sounds.

Alimentary System.—Abdomen: Lineae atrophicae; fundus of uterus 2 inches above symphysis pubis; liver and spleen both palpated 2 inches below costal margin.

Genito-urinary System.—No discharge per vaginam.

Special Examinations.—Vaginal swab: Direct smear and culture—no tetanus bacilli. Stool: Direct smear and culture—no tetanus bacilli. Urine: Trace of albumin; 1.7% sugar (lactose). Cerebrospinal fluid: Fluid clear, under pressure of 225 mm. H₂O, rising during spasms; a few lymphocytes and red blood corpuscles; sugar 166, chlorides 693, proteins 30 mg. per 10 c.cm.; no increase in globulin content. Serum calcium: 9 mg. per 100 c.cm. Blood count: R.B.C., 4,500,000; Hb 75% slight anisocytosis; W.B.C. 15,000—polymorphs 79%, lymphocytes 18%, eosinophils 1%, basophils 2%.

Progress of Case

Admitted one evening, the next day is taken as the first in this description.

1st Day.—Severe and frequent spasms of masseters, on an average at quarter-hour intervals; cervical rigidity, complaining of backache.

2nd Day.—Marked cervical rigidity, occasional spasm of back patient developing opisthotonos position; facial expression typical risus sardonius. Onset of foul-smelling sanguineous discharge from vagina.

3rd Day.—Marked cyanosis. Severe and frequent spasms of the back muscles; also of the jaws, causing the tongue to become extremely swollen and discoloured.

4th Day.—No change.

5th Day.—Spasms more severe than they had ever been before. Complaining of right-sided earache. Auriscopic examination—nothing abnormal.

6th Day.—Spasms less severe than yesterday, but frequent.

7th Day.—No change.

8th Day.—Spasms still severe. Vaginal discharge much less.

9th Day.—No change.

10th Day.—Urticarial serum rash developed; itching intense, aggravating the spasms. Discharge from vagina had almost ceased.

11th Day.—Rash still present, itching less intense following treatment with lotion. Spasms less severe and frequent—on an average at half-hourly intervals.

12th Day.—Rash disappeared. Spasms only of jaw muscles; aching of neck and back muscles. Taking semisolid diet.

13th Day.—Slight and infrequent jaw spasms.

14th Day.—Occasional jaw spasms. Tenderness of neck and back muscles on palpation.

15th Day.—No spasms. Tongue swollen and discoloured.

16th Day.—Patient put into general ward. Sitting up in bed taking almost full diet; tongue almost normal.

19th Day.—Massage instituted.

21st Day.—Allowed up a little.

24th Day.—Discharged from hospital.

Special Points

Pulse: Volume and tension never gave cause for worry; the rhythm was constantly regular, the rate 90, rising to 130 during the spasms. Blood pressure 130/75, rising during spasms.

Temperature rose to 99° F. on the third day, remaining for four days at that level, and then dropping to normal. The woman was an ideal patient; her morale was at all times high, and her

mind was lucid throughout the illness. She could always put the spatula in her mouth during the spasms to prevent damage to her tongue.

Treatment

General.—Special points to be emphasized: separate and darkened room; quiet enforced; special day and night nurses.

Specific.—Serum: 200,000 units concentrated A.T.S. intravenously the first day; 40,000 units intramuscularly the second, repeated on the third and fourth days.

Sulphonamide Chemotherapy.—Solu-septasine 10 c.cm. 5% solution four-hourly from admission for twenty-four hours, then 1 gramme sulphapyridine by mouth with an occasional injection of the former if the tablets could not be taken. Sulphonamide therapy stopped on the third day owing to the patient being markedly cyanosed.

Sedatives.—(1) Evipan sodium 0.5 to 0.75 gramme; intravenous and intramuscular injections enabled the patient to obtain four to five hours' repose. (2) Avertin, given in a dosage of 0.1 gramme per kg. body weight, provided lengthy and adequate rest. (3) Paraldehyde, 5 to 6 drachms rectally, was of little value. (4) Nembutal, 4½ grains by oral and rectal routes, gave very short periods of rest. (5) Chloral hydrate, 60 grains orally, gave much comfort during the day, two doses usually being sufficient. (6) Hypodermic injection of morphine 1/3 grain appeared a beneficial substitute for the chloral hydrate.

Diet.—We were always able to feed the patient by mouth with fluids, small and frequent quantities being taken through a straw. Fluids given: Horlick's, ovaltine, glucose fruit drinks, meat broths, bovril; egg, milk, and brandy beaten up together; also cream brought in by the patient's relatives. From the eleventh day she was able to take soft solids such as fish and vegetable purées, jellies, etc.

Oral hygiene: Mouth cleansed with glycothymolin swabs.

Back: This was treated daily.

Bowels kept open by gentle enema.

Rash: Calamine and carbolic lotion employed for this.

Vaginal discharge: Gentle hydrogen peroxide douches daily.

Differential Diagnosis

The conditions to be excluded in the diagnosis were tetany, strychnine poisoning, and local oral disease. Tetany is distinguished by the presence of hyperexcitability of the motor nerves and typical spasms of the limbs, all of which were absent in our patient. It is interesting to record the case of a woman, admitted two days after the one under discussion, who twenty-four hours after childbirth developed trismus and risus sardonius, associated, however, with carpopedal spasm, and who responded satisfactorily to calcium therapy.

Strychnine poisoning was excluded by the fact that the woman's muscles did not relax between the paroxysmal spasms, and local trismus by the absence of oral sepsis, etc.

Despite our inability to isolate the tetanus bacillus, confirmatory evidence of the diagnosis is implicit in the successful issue of the case following antitoxin therapy.

Discussion

It has been assumed in this case that infection with the *B. tetani* entered via the lacerated vaginal tissues. No positive evidence, however, can be offered to substantiate this assumption, smears and cultures being negative. We believe that we are justified in accepting the patient's statement concerning the absence of any other traumatic lesion that might have given rise to her condition. The presence of a foul sanguineous discharge per vaginam two days after admission is in our opinion strong evidence supporting our theory regarding the site of infection. Should the above conclusion be correct, whence did the offending tetanus bacillus originate? Here again we are faced with the lack of certain evidence.

We have no knowledge as to the asepis of the obstetrical procedures, and were unable to obtain any of the material

used in suturing the perineal lacerations. What importance can be attached to the fact that the baby did not develop tetanus? It is probable that the mother inoculated herself from the rectum, remembering that the bacterial flora of the human body can include the tetanus bacillus (Gardner, 1938; Mackie and McCartney, 1938). It is strange, therefore, that infection does not occur with greater frequency.

The long incubation period, slow development of symptoms, absence of marked pyrexia, and survival of the patient after ten days from the onset were all favourable points in assessing the prognosis.

Treatment consisted in providing adequate nourishment, assuring sufficient rest with a variety of sedatives, and the institution of tetanus antitoxin therapy, as recommended by Paterson of Australia (Price, 1937), an initial massive dose of 200,000 units being employed intravenously. It is probable that the intramuscular doses were unnecessary. No antitoxin was given intrathecally, one of us (B. M.) having seen cases of aseptic meningitis following the introduction of serum by this route.

Summary

A case of tetanus following childbirth is described, and the possibility of infection via a lacerated vagina or perineum discussed.

The merits of various sedatives employed are noted.

The success of antitoxin therapy along the lines suggested by Paterson of Australia is emphasized.

SAND-FLY FEVER AND BENIGN LYMPHOCYTIC MENINGITIS

BY

A. S. PEARSON, B.Sc., M.B., M.R.C.S.

Surgeon Lieut.-Commander, R.N.V.R.

During my period of service from May, 1940, to February, 1941, as acting medical specialist to the Naval patients at a general military hospital a number of cases of benign lymphocytic meningitis were admitted. It was observed that the symptomatology of this disease closely simulated that of sand-fly fever, and in a certain number of cases the diagnosis was established only after lumbar puncture.

The Army medical specialist—Major E. H. Evans—and I decided to investigate this similarity further. It was considered unreasonable and inadvisable to submit all cases of sand-fly fever to lumbar puncture. This form of investigation and treatment was therefore reserved for (1) cases sent in as meningitis; (2) cases sent in as sand-fly fever or pharyngitis, with a complaint of occipital headache or pain in the neck; (3) cases sent in as sand-fly fever, pharyngitis, or with any other diagnosis in which there was neck rigidity, head retraction, Kernig's sign, or other indication of a possible meningitis. Unfortunately before our investigations were completed I received a fresh appointment. It was therefore decided that I should publish my findings on the cases under my care, and that Major Evans should report his further investigations at a later date.

From August 7 to December 12, 1940, 15 patients were admitted who gave the necessary indications for lumbar

puncture: 8 proved to have benign lymphocytic meningitis and 7 had sand-fly fever. The season for sand-fly fever officially ends on November 18, so that the case admitted on December 12, which proved to be one of benign lymphocytic meningitis, would appear to disprove the association of the sand-fly with this form of meningitis. However, a sand-fly was killed in the medical mess a few days after this case was admitted. The patients were, of course, all men; 14 were 31 years of age or under, the other was 44. Major Evans demonstrated to me that the incidence curve of the cases of benign lymphocytic meningitis followed almost precisely the incidence curve of cases of sand-fly fever admitted during 1940.

With the exception of 2 cases the duration of the disease on admission was forty-eight hours or less. One of these exceptions was a case of sand-fly fever and the other of benign lymphocytic meningitis, and the duration was four and five days respectively. Progress in the two conditions was equally satisfactory and recovery was rapid. The treatment consisted of lumbar puncture and the four-hourly administration of a mixture of aspirin, phenacetin, and caffeine citrate. Sulphapyridine was not used.

Symptoms and Physical Signs

The following is an analysis of the symptoms and physical signs of the 15 cases:

	Benign Lymphocytic Meningitis (8 Cases)		Sand-fly Fever (7 Cases)	
	No. of Cases	%	No. of Cases	%
Symptoms				
Orbital pain	8	100	5	71.4
Photophobia	4	50	2	28.6

Lumbar puncture:				
Normal pressure	4	50	6	85.7
Slightly increased pressure	2	25	1†	14.3
Moderately	2	25	—	—
Cells: Lymphocytes	74—332 per c.mm. (Av. 183)		1—5 per c.mm.	

The cerebrospinal fluid was clear in all cases and reactions normal except for slightly increased protein content in the benign lymphocytic meningitis cases. This increase was in proportion to the number of cells present.

* One case two days before onset of sand-fly fever.
† Patient had right extensor plantar, which became normal after lumbar puncture.

Commentary

Analysis reveals that the cardinal symptoms and signs of sand-fly fever—namely, frontal headache, orbital pain, photophobia, pains in the back, fever, and conjunctival congestion—are duplicated in benign lymphocytic meningitis. Symptoms that may occur in both conditions but are more commonly present in sand-fly fever are diarrhoea, muscular pains, and to a lesser extent pains in the joints. Symptoms which may occur in both conditions but which are more commonly present in benign lymphocytic meningitis are occipital headache and vomiting. Pain in the neck, especially on flexion, was more frequently met with in benign lymphocytic meningitis, but was surprisingly common in sand-fly fever.

It will be observed that the temperature and pulse rate are higher in sand-fly fever and that congestion of the fauces is more common. Head retraction was not seen in any case of sand-fly fever and was most uncommon in the type of meningitis under discussion. Neck rigidity, however, was a fairly constant sign in benign lymphocytic meningitis, but was present also in 28% of the sand-fly fever cases. (It will be remembered that only cases which presented possible meningeal symptoms or physical signs are dealt with here.)

Abnormal ocular reflexes were equally rare in the two conditions. As regards peripheral nerve reflexes, it will be observed that without exception they were absent slightly more often in sand-fly fever than in benign lymphocytic meningitis. The only case showing a definitely abnormal plantar reflex proved to be a case of sand-fly fever. That patient also had cerebrospinal fluid under slightly increased pressure, and his plantar response returned to normal on the day after lumbar puncture. Kernig's sign was positive in only 50% of the cases of meningitis, and occurred in one case of sand-fly fever.

As a result of these experiences it was customary to suspect the case to be one of benign lymphocytic meningitis if the patient complained of occipital headache, pain in the neck, or vomiting. Moderate fever, comparatively slow pulse rate, neck rigidity, retraction of head, and any abnormal reflexes were also suggestive of this condition. Head retraction alone excluded sand-fly fever; and vomiting, slow pulse rate, moderate pyrexia, neck rigidity, and a positive Kernig were strong presumptive evidence of benign lymphocytic meningitis.

It is nevertheless true that several cases thought to be benign lymphocytic meningitis proved to be sand-fly fever, and vice versa, the examination of the cerebrospinal fluid producing an unexpected report. It would therefore appear that benign lymphocytic meningitis is made up of a group of diseases, and that the virus of sand-fly fever is capable of producing the condition.

The annual report for 1939 of the Director-General of Public Health, New South Wales, deals with a population of more than 2,700,000. The low death rate of 9.75 per 1,000 was nevertheless 5% above the average for the preceding five years; the birth rate was 17.46. The report states that the incidence of typhoid fever was the lowest yet recorded. Diphtheria shows some increase on the previous year, despite a widespread scheme of immunization, in which the State Government co-operates with local authorities. Satisfactory progress is recorded in the field of maternal and infant welfare. A consultant service is provided for the poorer patients; a mobile blood transfusion unit is also available. Every maternal death is reviewed by a medical committee. At the pre-natal clinics attendances increased by 40% over the figure for the previous year. This compares most favourably with the increase of 2% recorded in the preceding report.

PERSISTENT LACTATION WITH A NOTE ON CHIARI AND FROMMEL'S DISEASE

BY

BARTON GILBERT, M.D., F.R.C.S., M.R.C.O.G.

Surgeon to Out-patients, Chelsea Hospital for Women

The purpose of this brief communication is to draw attention to a case in which lactation had been established for the extraordinarily long period of fifteen years. Little is known of the pathology of this condition. The literature on the subject is mostly related to the association of persistent lactation with utero-ovarian atrophy. From this aspect the condition has been studied by Chiari, Braun, and Spaeth (1852-5), Frommel (1882), and more recently by Sharp (1935).

Between 1848 and 1855 Chiari, Braun, and Spaeth contributed a series of gynaecological articles from the Vienna clinics; in these Chiari discussed at some length the association of genital atrophy with prolonged lactation, and it appears that Simpson (1872) and Schroder were familiar with the syndrome. Chiari discusses two cases of puerperal utero-ovarian atrophy accompanied by persistent lactation. Frommel investigated a series of 3,000 labours and puerperia, and arrived at the conclusion that the incidence of uterine atrophy was not more than 1%. In his series the ages of the patients exhibiting the syndrome varied between 19 and 40 years, the average age being 29.6 years. Frommel believed the condition to be most common in women who had had numerous pregnancies, but it may arise after first babies.

The association of persistent lactation with utero-ovarian atrophy is known to some writers as Frommel's disease, but it would appear to be more correct to call it Chiari and Frommel's disease in view of the early writings of the elder Chiari.

Clinical observations indicate that persistent lactation and utero-ovarian atrophy coexist as described by Chiari, Frommel, and others; in some cases lactation may persist for longer periods than usual without evidence of genital atrophy, whereas in others genital atrophy may take place in the absence of prolonged lactation. Frommel records the case of a young woman who after her first pregnancy failed to lactate, but whose genital organs showed marked atrophy.

In Chiari and Frommel's disease atrophy of the uterus is always present, but the degree of atrophy varies from case to case. In some cases the uterus is very small and thin, the length of the cavity in one of the recorded cases being reduced to no more than 4.5 cm. The atrophic process also attacks the cervix, this organ having the appearance characteristic of senile women. In the majority of women suffering from this condition the ovaries are small and atrophic. Of Frommel's 28 cases only 3 had ovaries of normal size.

Menstruation does not always appear after weaning in cases in which this disease develops. It would seem that the development of amenorrhoea depends upon the degree of atrophy which has been attained.

The essential features of Chiari and Frommel's disease are therefore two in number—namely, utero-ovarian atrophy of variable degree, and persistent lactation which also varies in degree as demonstrated by Frommel's case; some women may have amenorrhoea as an additional feature.

Record of a Case of Persistent Lactation

The patient was a married woman 35 years of age. She had one child, aged nearly 16 years. Hospital advice was sought regarding the discharge of blood-stained milk from the left

nipple which had been noticed at intervals during the previous three months. Further inquiry elicited the information that she had lactated continuously since she had weaned her baby—namely, for a period of fifteen years.

Examination revealed mammary glands which were rather voluminous, and it was found that milk could be expressed from each of them with the greatest ease. A few red blood cells were present in the milk first obtained from the left breast. Nothing abnormal could be palpated in the substance of the breast. At the time it was thought that the presence of blood might be due to a duct papilloma or possibly to the rupture of small varicose veins within the breast.

Pelvic examination showed that the uterus was rather smaller than one would expect, firm in consistence, and normal in position. The menstrual losses lasted about four days and occurred at intervals of about a month. The menstrual periods had reappeared about six months after the birth of the baby, and had been constant since that time. Other than the features already mentioned, no evidence of disease of the pituitary gland was discovered.

It was apparent that the patient believed it to be perfectly natural for a woman who had borne a child to lactate for the remainder of her reproductive life, and she did not deny that it was her custom to stimulate the production of milk by expressing it manually every day.

Commentary

This case is of interest in so far as it is one of those rare examples in which lactation persists for many years—in this instance for fifteen years after weaning the baby. It is hardly to be regarded as a case of Chiari and Frommel's disease, as the degree of utero-ovarian atrophy is of a minor nature—certainly not so profound as to cause any menstrual changes. Nevertheless other writers have pointed out that the degree of atrophy varies from case to case, and it is possible that this patient is an example of the mildest variety of genital atrophy associated with prolonged lactation.

It is of especial interest to note that daily manipulation of the breasts had been practised by the patient, and it is possible that this may have been just as influential in prolonging lactation as it is in the case of certain well-known domestic quadrupeds.

Medical Memoranda

The Blood Supply of Human Heart Valves

Accurate knowledge of normal structure is important in clinical medicine, as anatomical characteristics often throw light on or suggest explanations for some of the mechanical components concerning the localization of disease processes within the body or a tissue. The structure of normal human heart valves, for example, must be properly understood before the histological basis of the pathogenesis of valvulitis can be appreciated.

In view of the importance of such knowledge it is unfortunate that three recent textbooks (Baitsell, 1940; Grant, 1940; Maximow and Bloom, 1939) depict normal human atrio-ventricular valves as containing a richly anastomosing network of blood vessels extending from their bases to the free margin. All quote the authority of Bayne-Jones (1917), and all reproduce the drawing made for him by Max Brödel. It is a semi-diagrammatic figure based on the injection of several specimens and purporting to give a "composite picture of the typical vascular anatomy of a completely injected human mitral or tricuspid valve." The reason for the production of such a composite figure is in itself puzzling, as Bayne-Jones laid no claim to have succeeded in making a complete injection in any valve or cusp.

WORK OF GROSS

The question of the presence or absence of blood vessels in normal human heart valves was for long of a controversial nature, but the final report by Gross (1937), in which he summarizes in admirable fashion the various difficulties that have hindered the true solution of the problem, leaves no doubt as to the non-vascular nature of these structures. Gross's final contribution is of particular significance in view of the fact that he and his collaborators had previously adduced evidence which favoured the belief that blood vessels may exist in a small percentage of normal human heart valves (Gross, 1921; Kugel and Gross, 1926; Ritter, Gross, and Kugel, 1928). Re-examination of their material and of many hundreds of additional specimens, however, led them to express doubt as to the normality of any human heart valve possessing blood vessels (Gross and Friedberg, 1936; Gross and Kugel, 1931). Dow and Harper (1932) reached a similar conclusion.

The presence of blood vessels in heart valves the site of an inflammatory process is undoubted, and it had been shown that they ramify for the most part in the subendothelial zone of the affected cusps. The most probable explanation for their presence is that they have been formed in response to toxic or bacterial injury of the cellular elements of the cusp. The exact nature of the injury is not completely understood, but the work of Gross (1937) clearly indicates that rheumatic fever which had completely regressed clinically is responsible for their formation in many instances. He states: "The supposedly normal vascularized series owes the presence of blood vessels in the valves to a previous mild and in most instances completely healed rheumatic process." Harper (1940) described the reaction of valvular tissue and its relation to the formation of new blood vessels in a case of early rheumatic valvulitis.

DISCUSSION

In the subendothelial zone of normal human valves there are several cell types, many of which under normal circumstances are probably non-motile elements playing an important part in the general metabolism of the cusp. In valvulitis they are activated and produce other cell types. This reaction is primarily one of local defence, but it is also evident that it is secondarily associated with the establishment of new blood vessels within the cusps (Harper, 1940). In the light of these observations it is clear that primary embolism cannot be considered a factor in the genesis of endocarditis in man.

With reference to work on experimental endocarditis it must be emphasized that the significance of the presence or absence of blood vessels in the normal cusps of the animals used has not been sufficiently appreciated. Blood vessels occur normally in the heart valves of certain species—for example, cat, dog, sheep, goat, pig, ox, and horse. These cannot be regarded as analogous to those sometimes occurring in man, which, as explained above, are of inflammatory origin. Rabbit heart valves conform to the human type (Harper, 1938).

These observations have obviously a direct and important bearing on the interpretation of experimental results, and indicate also the care that must be exercised in the comparison of results of experiments on different mammalia. Thus it is essential that statements on details of normal structure should be accurate not only from the purely histological point of view but also from their bearing on the interpretation of disease processes.

Reviews

MODERN SCIENCE AND THE LEGACY OF
ANCIENT LEARNING

A Short History of Science to the Nineteenth Century. By Charles Singer. (Pp. 400. 8s. 6d. net.) Oxford: The Clarendon Press. 1941.

To inquire why men thought what they did when they did is always an engaging enterprise, and this is the keynote of Dr. Charles Singer's *Short History of Natural Science*. Well known as a most learned authority on the subject, he has in this book so presented the facts as to fascinate anyone interested in the history of ideas. The final exposition of an individual discovery is very different from a description of the steps by which it was reached, but by taking a more extended view of the sequence of ideas, Dr. Singer labels each epoch with its leading motive in a manner which is helpful and impressive.

Thus we start with the emergence of mental coherence in the Greek world when philosophy became based on natural science to the neglect of ethics; then Plato and Aristotle sought to adjust their rival claims, with a preference for ethics, while repudiating the popular religion of the day. This he calls the Great Adventure. Next Alexandrian thought developed separate departments for science, ethics, and religion, and ended with definite scientific deterioration. Intellectual nerve was failing. Under the Roman Empire, the prevalent schools of thought were largely indifferent to science, which deteriorated still further. Scientific inspiration waned to nothing. The vision of the Stoics "was very different from that given by the spacious claim of modern science. . . . It was an iron, nerveless, tyrannical universe . . . in which the Roman thinker must have felt himself fettered, imprisoned, crushed. He had abandoned the faith of his fathers and . . . found himself embracing a machine. . . . It was reaction against this pessimism which led to the great spiritual changes in the midst of which antiquity went up in smoke." And so followed the Dark Age characterized by the Failure of Knowledge just because to the mediaeval mind the world seemed completely knowable in both space and time—and thus not worth knowing. Without curiosity there can be no science, and if the whole scheme of things is regarded as having been revealed once for all, what basis for curiosity remains? Then came the Revival of Learning: seeking to penetrate the dark shadows the humanist tried to discern the antiquity that was beyond. And as he strained his eyes, another vision, a reflection perhaps of himself, came sometimes to him. Then "the vision would be clouded over by that terrible erudition which in the absence of general ideas has been and is one of the enemies of science." Leonardo, Vesalius, and Galileo were more truly the heirs of Plato and Aristotle than were the editors of their texts. For it is living literature, art, and science and not classical scholarship that inherited the legacy of ancient wisdom. That was where the revival of learning failed until the Insurgent Century (that is, the seventeenth) made new attempts at a synthesis aided by the weapon of the experimental method.

The eighteenth century, using the Newtonian key to the mathematics of the heavens, enthroned determinism. And so we are led on to the development of modern science, and the change of thought produced by the doctrine of evolution, in itself a return to the Greek idea that everything is in a state of "becoming." In conclusion Dr. Singer sees the dawn of a stage in which an adequate scientific equipment will involve some regard to the world

as an interconnected whole, in which science and philosophy will dwell less apart, though science must of necessity restrict itself to phenomena. But for science merely to quote authority is useless. The demand for evidence, for tangible data, for experience that can be repeated at will, has created science as we know it.

"Everyone is by nature a disciple either of Plato or of Aristotle," and one might add as a corollary, is either an introvert or an extrovert. Yet surely no one is entirely one or the other, for "our minds, as much the product of evolution as our bodies, have in the ages developed as mirrors of the world in which we dwell; they are attuned to Nature. The mathematical thought of ages on the nature of certain curves elaborated a knowledge which Kepler and Newton fitted into the phenomena of planetary movements. The minds of the pre-Keplerian mathematicians . . . were working on Nature's lines, though they knew it not." With which pregnant saying we must leave this book, which it has been an intellectual pleasure and stimulus to read.

BACILLARY AND RICKETTSIAL INFECTION

Bacillary and Rickettsial Infections: Acute and Chronic. A Textbook. By William H. Holmes, Professor of Medicine. Northwestern University Medical School. (Pp. 676. 25s. net.) New York and London: The Macmillan Company. 1940.

To the series entitled "Orientations in Medicine" Dr. William H. Holmes of Chicago has contributed a volume on *Bacillary and Rickettsial Infections: Acute and Chronic*. Actuated, as many of his predecessors have been, by the belief that the present can be perfectly comprehended only by a knowledge of the past, the author endeavours to trace the history of each disease so far as it is known from the earliest times to the present day. Symptomatology, epidemiology, and bacteriology are closely intermingled. Pages are spent on quotations from ancient writers. History is enriched by anecdote, and references to the Bible are numerous. Our modern knowledge is sometimes given very fully, sometimes but briefly. Long chapters are spent on typhus, typhoid, and tuberculosis; anthrax is dismissed in a few pages. The result is, as the author admits, unconventional. The volume cannot be regarded as a systematic treatise of either the history of medicine, clinical medicine, bacteriology, or epidemiology, but it comprises a mixture of these, along with some immunology and treatment, which are likely to afford more pleasure to the casual reader than to the earnest seeker after knowledge. The book is supposed to be for students, but rightly or wrongly we doubt whether students in this country would welcome a mode of presentation in which so much stress is laid on the historical method of approach, especially when the history is apt to be incomplete and to be neglectful of the German literature. To write so fully on typhus fever and its diagnosis without describing the original observations of Weil and Felix, or on tuberculosis without mentioning the work of the Royal Commission, leads inevitably to the feeling that the author's own knowledge is imperfect or his judgment of doubtful validity.

For the qualified man and for the interested lay reader the book presents much that is attractive, and it is likely to command a wide circle of readers. Its subject-matter is confined strictly to diseases caused by bacilli and rickettsiae. Other bacterial diseases, such as those due to coccid, spirochaeta, or protozoal organisms, are reserved for another volume. There is a good deal of carelessness over the spelling of authors' names, especially in the text, which is frequently at variance with the bibliography. Greater attention might be paid to this defect in a subsequent edition.

HAEMORRHOIDS

Haemorrhoids and their Treatment: The Varicose Syndrome of the Rectum. By Kasper Blond, M.D. Vienna. Translated by E. Stanley Lee, M.S., F.R.C.S. (Pp. 140. 15s. net.) Bristol: John Wright and Sons, Ltd.; London: Simpkin Marshall, Ltd. 1940.

A specialist's general outlook is bound to be influenced more or less by the nature of his specialty. The author of *Haemorrhoids and their Treatment* sees much disease from a proctological point of view; thus many cases of so-called prostatic hypertrophy, he tells us, are really cases of acute congestion or oedema of the prostate brought about by impairment of its venous return, and many prostaticectomies could be avoided if a proper examination were made with a proctoscope. At the same time, and to do him justice, he does bring a general view to bear upon his own specialty, and asserts that the rectal varicose syndrome is not a localized disease of one organ but rather an indication of the dysfunction of the whole alimentary tract. This is essentially sound, and he will no doubt find many to agree with him that in the apparently healthy person haemorrhoids are usually due to overeating. If this contention is correct in these days of rationing, fewer should be troubled with so-called attacks of piles and their complications.

Dr. Blond's thoughtful book is refreshing from the fact that it does not closely follow the beaten track of current opinion. But such a departure from custom as to call anal fissures "thrombophlebitis marginalis recta chronica" may savour of a striving after effect, which is really quite needless since there is so much in the book that is good. A novel view put forward is that pruritus is a toxic manifestation of portal blood in the peripheral systemic venous circulation caused by a backflow where the two venous systems anastomose—between the superior and inferior haemorrhoidal plexuses. The author suggests that scrotal, vulval, and even anal eczema are all due to a retrograde flow of portal blood into the pelvic veins, and, in the case of the crural lesion, downwards into the incompetent saphenous system also. This explanation is ingenious, to say the least of it, and there is much in the monograph that is well worthy of study by general surgeons, proctologists, and practitioners. Mr. Stanley Lee has done a service in translating Dr. Blond's work for us, and the publishers have produced a very readable and well-illustrated volume, attractive in appearance and convenient in size.

Notes on Books

In producing an 84-page booklet, *Canteen Catering*, the Ministry of Food has shown forethought in taking into consideration a variety of needs and tastes. A feature of the booklet is its division into sections for (a) dishes suitable for England and Wales; (b) menus, including broth and black puddings, more acceptable to the Scottish palate; (c) light summer meals; (d) subsidiary dishes for night workers; (e) square meals, easily cooked in an emergency; (f) special vegetable recipes; and (g) sandwich spreads. Stress is laid on the need for "protective foods" to counteract the deficiency in the average diet, and it is particularly advised that raw vegetables should be used when fruit is deficient. Sound advice is given on the introduction of innovations of this kind: make no sudden change, introduce unfamiliar foods into dishes which are known and liked, serve raw vegetables first as a garnish and gradually increase the quantities to form a salad, and so on. It is pointed out that the catering staff should appreciate the value of the foods served in order that they may help in popularizing them. This valuable book is being distributed free to industrial canteens, British Restaurants, Londoners' Meal Services, and to other large-scale catering organizations. It is also available, price 8d. post free, at H.M. Stationery Office, Kingsway, W.C.2.

SATURDAY AUGUST 30 1941

SULPHONAMIDES AND THE NERVOUS SYSTEM

The two most alarming reactions associated with the sulphonamides are agranulocytosis and acute haemolytic anaemia. Toxic effects on the nervous system have, however, been recorded from time to time. Headache is not infrequently encountered, associated in some cases with such diverse symptoms as drowsiness, loss of memory, dizziness, palpitation, paraesthesia, loss of taste, tinnitus, and lack of orientation, while there is evidence to suggest that vomiting may be central rather than peripheral in origin. More serious have been persistent hiccup (Wyman¹), difficulty in speech, severe abdominal cramps, and in at least a few cases the onset of definite psychoses. A point of importance is that the nervous symptoms may not appear until some days after the withdrawal of the drug. In this connexion it should be remembered that mechanical judgment is often impaired after taking sulphonamide drugs. It is doubtful, for instance, whether any pilot should be allowed to fly for at least four days after taking sulphonamides, while at least one railway accident in which a number of people were injured has been ascribed to the fact that the engine driver was taking sulphanilamide. Still more serious reactions to sulphonamides are the cases of demyelination of the spinal cord after sulphanilamide, recorded in two patients by Fisher and Gilmour² and in one patient after uleron and disethyl B by Schubert.³ Roseman and Aring⁴ also have recently described what at present is a unique case of haemorrhagic encephalitis after the administration of sulphamethylthiazole. This condition, associated with perivascular haemorrhages and in some instances focal perivascular areas of necrosis, is most frequently produced by heavy metal compounds, such as the arsphenamines, and by some of the alkaloids, particularly the opiate group. In the patient who was given sulphamethylthiazole, 112 grammes in six days, both perivascular haemorrhages and focal necroses were present, together with changes in the endothelium of the blood vessels, leading at times to complete occlusion with resulting anoxaemic damage to the neurones: the lesions, however, were found in the grey matter of the cerebral hemispheres and brain stem rather than in the white matter, as is usually the case in typical haemorrhagic encephalitis. Johnstone and Forgacs⁵ have in these columns called attention to the fact that symptoms resembling those of meningitis may be produced by sulphapyridine in persons with meningococcal meningitis: in five cases, though the cerebrospinal fluid became quite normal, the symptoms continued or, if the drug was

still administered, became intensified; but if therapy was stopped the meningeal symptoms promptly disappeared.

Whereas severe reactions involving the central nervous system have fortunately been extremely rare, those involving the peripheral nervous system have been not infrequent. In 1938 Long and Bliss⁶ noted two cases of peripheral neuritis associated with sulphanilamide therapy, but very few instances have been reported. Waugh⁷ observed foot-drop in a man who had taken 40 grammes of sulphanilamide in nine days, while Ornsteen and Furst⁸ reported toxic neuritis in both lower limbs associated with progressive muscular dystrophy. Albucid has also on rare occasions given rise to peripheral neuritis: in one patient with ulnar neuritis due to this compound Matzdorff⁹ found that vitamin B₁ was of considerable value. Peripheral neuritis has not been reported with sulphapyridine, but with disulphanilamide (DB 32, sulphanilyl sulphanilamide), the dimethyl derivative (uleron), the monomethyl derivative, and with sulphamethylthiazole, many cases have now been described, more especially in Germany. With disulphanilamide and its methyl derivatives the distribution of the neuritis is symmetrical, affecting more especially the flexor muscles of the wrists, the interosseous, adductor, and opponens pollicis muscles of the hands, the flexors and occasionally the extensors of the ankle-joints. The paralysis is often of long duration, and an incomplete reaction of degeneration may be given by some of the muscles.

Sciatica may also occur, together with dysaesthesia and disturbances of the autonomic system. Mahoney and his colleagues¹⁰ reported pains and cramps in the muscles of the arms and legs after sulphamethylthiazole therapy, and Brown and Herrell¹¹ observed three instances of peripheral neuritis among 106 patients treated with this compound. Two cases of nervous involvement after administration of sulphathiazole have been recorded by Bieter and his colleagues¹²: one patient developed foot-drop and deafness in one ear, the other tingling and numbness of the fingers of both hands. No data are yet available for sulphaphenylthiazole and other recently discovered sulphonamide derivatives. A single case of optic neuritis has been recorded by Bucy¹³ after sulphanilamide treatment. The sight became defective, and on examination absolute scotomata for red and blue and relative scotomata for white were discovered: the disks were swollen and reddened. After cessation of treatment it took about a month for normal vision to be restored.

The toxic action of the sulphonamides on the nervous system in man has been very fully confirmed by animal experiments. Doses of 1.5 to 2.0 grammes per kilo of body weight given to rabbits were found by Hawking¹⁴ to cause weakness of the legs, dyspnoea, a rigid extension of the limbs and contraction of the head resembling decerebrate rigidity: in a few animals degenerative

changes were present in some of the anterior horn cells of the spinal cord and in some of the cortical neurones. In mice there were incoordination and paralysis. In dogs, sulphanilamide in doses of 1 gramme per kilo produced salivation, vomiting, diarrhoea, hyperpnoea, muscular weakness, ataxia, and, finally, spastic rigidity of the limbs with loss of sensation. Blindness came on, and placing reactions associated with an unimpaired cerebral cortex were absent (Marshall *et al.*¹¹). Rosenthal¹² and Nelson¹³ also studied the effects of sulphanilamide and disulphanilamide on rabbits and chickens, while more recently Bieter and his colleagues¹⁴ have compared the effects of sulphanilamide, sulphapyridine, sulphathiazole, sulphamethylthiazole, uleron, and sulphaphenylthiazole on chickens, which on the whole are far more sensitive to the sulphonamides than the rabbit or man. Varying degrees of injury to the myelin sheaths of peripheral nerves and to the myelin sheaths and axones of the spinal cord were noted: sulphanilamide and sulphapyridine were found to be the least injurious, followed in ascending order by sulphathiazole, sulphamethylthiazole, uleron, and sulphaphenylthiazole. Under certain conditions, which are at present obscure, and after repeated doses, some accumulation of the drugs occurs in the sciatic nerves.

In view of these effects on the central nervous system the results of the local application of sulphonamides to the brain are of much interest. Russell and Falconer¹⁵ found that local application of solid sulphanilamide and solid sulphapyridine to the rabbit's brain did not cause any appreciable damage, although excess of either substance caused a foreign body reaction. Since sulphanilamide is more soluble than sulphapyridine it is to be preferred for local application. Hurteau¹⁶ also found in cats that the local application of sulphonamides to the brain caused a mild focal leucocytic response which rapidly disappeared from the meninges, while the actual focal reaction was much less than from the implantation of silk sutures or silver clips. The drug could, however, be seen either microscopically or macroscopically in the brain tissues as late as twenty days: chemically, sulphanilamide could be detected up to eleven days, sulphathiazole up to seventeen days, sulphapyridine up to thirty-four days. There was no constant evidence of neuronal destruction or glial reaction from application of drugs to excised wounds of the brain, while the ultimate results of the healing of wounds to which the drugs have been applied does not suggest that they increase the extent of scarring.

INTERRELATIONS OF THE THYROID GLAND

When in 1891 G. R. Murray first successfully treated a case of myxoedema by injections of thyroid extract he not only initiated a rational endocrine therapy but proved that the thyroid was an organ of internal secretion and was not excretory in function, as had previously been believed. We now realize that this gland and other

endocrine structures have complicated interrelations, some of which are not easy to interpret. The influence of the anterior pituitary on the thyroid is fairly well defined. The presence of some thyrotrophic principle in the pituitary could be deduced from its tendency to enlarge when thyroid function is depressed, and from the involution of the thyroid which follows ablation of the pituitary in tadpoles and rats. Anterior pituitary extracts cause hypertrophy of thyroid cells even *in vitro*, and that this is an attempt at compensation is shown by the presence of a thyroid-stimulating substance in the blood of thyroidectomized animals and in myxoedematous patients. As for relations with the gonads, it has long been known that the thyroid may enlarge at puberty, menstruation, pregnancy, and the menopause, but the mechanism is not so clear. Oestrone seems to depress thyroid activity, while androgens may stimulate it. From a number of rather confusing observations Marine¹⁷ concludes that thyroid enlargement is most likely to take place at the point in the menstrual cycle when oestrogens are at their lowest level; yet myxoedema is apt to occur at the menopause. It is to be hoped that further research will result in a more consistent story.

The relation between the thyroid and adrenals is complex but more intelligible. It is important to distinguish between cortex and medulla in this connexion. The evidence is that the cortex and the thyroid are antagonistic in action. Indeed the total picture of Graves's disease, with its creatinuria, loss of hair, muscular weakness, achlorhydria, pigmentation, and persistent thymus, implies adrenal cortical insufficiency. On the other hand all recent work supports the original view of Asher and Flack that the thyroid hormone increases the response to adrenaline of the sympathetic nervous system and the tissues innervated by it. Some such interrelation is further indicated because thyroxine and adrenaline are both derivatives of tyrosine and each is a powerful activator of metabolism. In Graves's disease, then, we find antagonism with the cortex and synergism with the medulla of the adrenals. The persistent enlargement of the thymus in Graves's disease is well known, and Hoskins has found that feeding guinea-pigs with thyroid causes the thymus to enlarge. This is a corrective antagonism, for as long ago as 1912 Gudernatsch observed that feeding tadpoles with thymus retarded metamorphosis and offered some protection against the effects of thyroid. Moreover immature animals are less sensitive to thyroxine than adults unless their thymus is removed. Therefore thymectomy, as once recommended for Graves's disease, is clearly contraindicated. Although the independent functions of the thyroid and parathyroids, once fiercely contested, are now universally accepted, it would appear they are complementary in respect of calcium and phosphorus metabolism. Aub has shown that in Graves's disease calcium excretion is greatly increased, while in myxoedema it is decreased. The well-known osteoporosis of the former condition recalls the bony changes of hyperparathyroidism. A considerable but conflicting literature has accumulated on the relation of the various vitamins to thyroid function, but, as Means has pointed

out, there is no evidence that their administration gives appreciable benefit either in Graves's disease or in myxoedema.

In the same journal as Marine's paper there is an interesting and important communication by Lichtwitz² on hypothalamic-pituitary syndromes. It supports the views recently expressed in these columns.³ An observation of some topical interest is that the last twenty-five years have produced a larger number of tall individuals with long limbs and a relatively short torso on which is perched a small head with a long face. In 1930 Harvey Cushing called attention to the increased height of American undergraduates which occurred during his lifetime: whereas when he entered his university only 5% of the students were six feet or more in height, forty years later 20% reached this stature. This points to a change in pituitary-hypothalamic activity, linked with a eunuchoid type. Its somatic characteristics are paralleled by a definite mental pattern. These individuals are emotional rather than rational; they have little stability, lack self-confidence, and dread to assume responsibility. Hence they are easily herded by a man who claims to be their leader and holds out prospects of greatness. It is interesting that in the present Germany this infantile gigantism is portrayed, in the statue of Siegfried, as the ideal of manhood. Here is an evolutionary change fraught with the dangers that beset us to-day.

PENICILLIN: AN ANTISEPTIC OF MICROBIC ORIGIN

We seem to be at the beginning of a new antiseptic era, and not the least promising of the anti-bacterial agents awaiting clinical trial are substances produced by bacteria themselves. Although examples of antagonism between bacteria have been noticed for many years, the thorough investigation of this phenomenon was neglected until the work of Dubos, whose method and results we described briefly not long ago.⁴ Starting with a mixture of soils calculated to contain a great variety of bacteria, he fed it for two years with nothing but a particular bacterium, thus selectively breeding out from the original flora those species which could attack and subsist on the bacterium added as pabulum. Thus he isolated a sporing Gram-positive bacillus now recognized as *B. brevis*, which is highly antagonistic to staphylococci and many other Gram-positive bacteria. An extract of this organism proved to be an antiseptic of astonishing potency, not only active *in vitro* but capable, for example, of curing experimental pneumococcal infection in mice. This substance, now known as "gramicidin," has properties well worthy of therapeutic trial. Dubos and Hotchkiss⁵ have recently isolated from *B. brevis* another agent, "tyrocidine," which acts also on Gram-negative bacteria but only *in vitro*, and in this and its more toxic properties for mammalian cells rather resembles the older sort of antiseptic.

Another example of antagonism, known for many years, has now been restudied with remarkable results. This story goes back twelve years to the accidental contamination of a plate in Fleming's laboratory by the spore of a mould, a trivial and commonplace occurrence which was to

have immense consequences. The original colony of this mould, which proved to be *Penicillium notatum*, inhibited the growth of staphylococci in its vicinity, and fluid cultures of it contained a substance, since known as "penicillin," which was strongly inhibitory to the growth of various mainly Gram-positive bacteria. It came to be used at St. Mary's Hospital and elsewhere as an ingredient in selective culture media, and does not appear to have been considered as possibly useful from any other point of view. The wider possibilities of penicillin have been explored at Oxford by a team of workers directed by Prof. H. W. Florey and E. Chain,⁶ who now present an extensive report on their various studies. Earlier observations briefly reported last year suggested that penicillin might be of use as an antiseptic, and the first further step was to provide for its production on an adequate scale. This was not an easy matter, for the larger the scale of cultural work the greater is the risk of contamination, and it appears most unlikely that supplies of penicillin for general use will be available for some time to come. It was found possible to purify the substance to a degree hitherto unattempted and to store it; an arbitrary unit of potency has been adopted, and a simple method devised for assessing potency. The purified product inhibits the growth of *Staphylococcus aureus*, *Streptococcus pyogenes*, and certain other bacteria in a dilution of 1 in 1,000,000 or more. Serum, blood, and pus do not interfere with this effect, and it is exerted on a large as well as a small inoculum, a feature of the action of penicillin in which it is superior, at least in *in vitro* performance, to the sulphonamides. High concentrations relative to those which should be needed to secure antiseptic action were found to be innocuous to leucocytes and to fibroblasts in tissue culture. Penicillin can be given to animals and man intravenously without evident toxic effect, and continuous administration by this route maintains a bacteriostatic concentration in the blood. It is excreted mainly in the urine, but also in the bile and saliva; it was not found in pancreatic juice or cerebrospinal fluid. Acid and the action of insusceptible bacteria destroy it; hence it needs to be protected by alkali if given by the mouth, and is decomposed if given by rectum. The culmination of all these studies was the administration of penicillin by intravenous drip to several cases of staphylococcal pyaemia with evident favourable effect. Given by the mouth with sodium bicarbonate it also served to clear up a staphylococcal infection of the urinary tract; local application to the eye in conjunctivitis was also successful.

These are only the main facts emerging from a very comprehensive study in which a large team of workers is engaged. Laboratory investigations have been carried from every possible aspect to a point amply justifying clinical trial; but the few cases studied—few because the production of penicillin could keep pace with no more—serve only to show that there is one infection at least, and that among the most resistant to all other forms of chemotherapy, which can be favourably influenced even in its gravest form. The list of bacteria susceptible *in vitro* to the action of penicillin is a long one, and includes such various micro-organisms as the meningococcus, the anthrax bacillus, and *Actinomyces hominis*. The wider possibilities of this form of treatment will doubtless be explored as far as possible by the method of local application, if only for the sake of economy in material. Continuous intravenous administration, though consuming large amounts, can be made less wasteful by extracting penicillin from the urine and using it again; that this novel proceeding was actually resorted to and worth while makes it appear that at the moment penicillin is to other antiseptics not unlike what radium is to other metals.

FATALITY IN A BLOOD DONOR

Since the outbreak of war thousands of pints of blood have been withdrawn from donors all over the country without the report of any serious mishap. In the majority of cases blood is taken by simple gravity, but in some instances suction is applied to the bottle either by an electric pump, a Higginson syringe, or an electric rotary pump such as was described by Biddle and Langley in 1939 in this *Journal*.¹ Recently a fatal case of air embolism has occurred due to a pump of the latter type reversing its action. An expert from the factory who had made the pump was not aware that such a thing could happen. There was a valve in the pump which was unfortunately out of action due to a piece of foreign matter, but this valve was not placed in the pump for the purpose of preventing such an action but only to stop surges if the pump failed. The pump works on alternating current, and reversal occurs only if the rotor is in a certain position and the pump is switched on from the wall plug and not from the switch on the pump. On the occasion of the disaster, suction had proceeded satisfactorily until an assistant under a misapprehension switched the current off for a moment. The motor of this type of pump can be made safe by the installation of a condenser to prevent reversal. Additional safeguards are a safety valve in the suction current and careful directions as to switching the current. It is hoped that any hospital making use of the rotary suction pump will take steps to have the necessary alterations made in the apparatus. At the moment, when the good will of donors is so essential to the welfare of both Service and civilian casualties, no expense is too great to ensure that the health of the donor is safeguarded.

RECOVERY FROM CRUSH SYNDROME

Respite from air raids has given opportunity to examine more closely the data on the casualties of the winter and spring and to follow more thoroughly the trains of thought that these suggest. The syndrome associated with crush injury occurring in patients buried under the debris of a bombed house has been the point of departure of several hypotheses. On the theory that the syndrome is due not to the liberation of toxic bodies from the crushed tissues into the general circulation but the reverse—loss of blood constituents into the injured limb—Patey and Robertson² suggest the use of intermittent positive pressure with a Pavaex apparatus. Of the two cases they treated thus, however, one was already past the danger period (the first week) and the second showed no signs of shock or renal impairment except a few red corpuscles in the urine. The surgical problem of gangrene so often encountered in these crushed patients has also been tackled by using fascial splitting incisions, on the theory that pressure in deep fascial compartments itself produces tissue damage. This has been made the main subject of an extremely careful and detailed case-study by a group of workers at the London Hospital.³ Observations were made on the contractility and appearance of the individual muscles exposed by this procedure: biopsy specimens were taken, both at the time and later in the patient's recovery. Two muscles in strong fascial compartments were non-contraction and showed severe necrosis thirty-three hours after release. Other muscles not so confined, though pale and watery, contracted normally and showed only moderate necrosis. This

selective damage was thought to be not the direct result of localized trauma but the result of tension inside strong fascial sheaths. This type of intervention is designed to save the limb and prevent ischaemic muscle damage; it may equally increase resorption from already damaged tissue, an action not to be desired if renal damage is due to tissue breakdown products. It has been shown that such substances do enter the blood, and the pigment in the urine of such patients has been identified as myohaemoglobin.⁴ As has been more recently pointed out,⁵ this was put forward as a possibility as long ago as 1923 by Minami, working on material collected by the Germans during the war of 1914-18. Efforts directed towards combating this systemic result of injury may perhaps be of major importance in the coming winter: comparison of the possible therapeutic value of cortical hormone, alkalization, and diuretic measures is urgently needed, and will call for thorough observation and unremitting attention if any convincing proof of benefit is to be obtained. In this connexion the case recorded in these columns by R. G. Henderson⁶ is of interest: glucose and isotonic sodium sulphate were given intravenously on the seventh and following days. This was followed by diuresis and recovery. A more complete study of a similar case is recorded by Longland and Murray.⁷ In spite of potassium citrate (grains 360) by mouth daily from the third day, the urine became alkaline only on the sixth day, but the output increased and recovery ensued despite a blood-urea level of 375 mg. per 100 c.cm. This case was unusual since it presented obvious signs of haemolysis, to which, in the presence of acidosis, the authors ascribe the renal lesion. Further careful studies like this are needed. The mechanism by which the local lesion produces the systemic disturbance (if it does so) must be clarified before we can integrate in any rational way the treatment of the local and that of the systemic condition. This will demand that complete and effective co-operation between surgeon and physician, pathologist and physiologist, which we may hope and expect as one of the few, if indirect, benefits of these unhappy times.

THE SPREAD OF POLIOMYELITIS

The view that human poliomyelitis is a disease of the nervous system alone has never been wholly acceptable either to clinicians or to epidemiologists. Up to a short time ago, however, it was generally held that the epidemiology and pathogenesis of the disease in man were essentially similar to those in monkeys, the usually accepted view (cf. Faber⁸) being based chiefly on the work of Fairbrother and Hurst,⁹ who worked with the rhesus monkey *Macaca mulatta*. In this species poliomyelitis appears to be a disease strictly confined to nervous tissues, the only "natural" route of infection being by the olfactory nerves. The view that in man also this was the usual portal of infection was supported by the fact that, from 1911 to 1937 (cf. Kramer *et al.*¹⁰), of 535 attempts to recover poliomyelitis virus from the nasopharynx of persons either suffering or convalescent from poliomyelitis sixty-four yielded positive results. During the last few years, however, there has been a tendency to look for primary infections of poliomyelitis virus in non-nervous tissues, thus going back to suggestions made many years ago. In 1911

Lovett and Richardson¹¹ reported that of 419 cases of poliomyelitis observed from 1908 to 1910, 105, or rather more than 25%, had been swimming, wading, or paddling in more or less heavily contaminated water shortly before the onset of their attack. In 1912 Kling, Pettersson, and Wernstedt,¹² working in Stockholm, attempted to isolate the virus by inoculation into monkeys: in this way they claim to have isolated the virus from the intestinal tract of human beings thirty-six times out of fifty. No more passages were made, however, though in 1915 Sawyer¹³ obtained one strain of virus from the stools of a convalescent. This was given further monkey passage. Recently, groups of workers in America, Sweden, and France have independently isolated poliomyelitis virus from the faeces, particularly of non-paralytic cases. In Trask, Vignec, and Paul's¹⁴ case the virus was isolated two, eleven, and twenty-five days after onset, while Lépine and Sedallian¹⁵ reported its isolation from the faeces forty-one days after an apparently abortive attack of the disease. On two occasions Paul, Trask, and Gard¹⁶ succeeded in isolating poliomyelitis virus from sewage in cities where the disease was epidemic. These results suggest that at least in non-paralytic cases large quantities of virus are present in the intestinal contents, and that multiplication of the virus takes place in some tissue closely related to the intestinal tract. Burnet and Jackson¹⁷ have recently found that in the monkey *Macacus irus*, infected orally, the mesenteric lymph nodes almost always contain the virus in such large amounts that it could hardly have been conveyed by centrifugal spread along nerves from the central nervous system. Since multiplication within lymph nodes seems unlikely, though it cannot be ruled out, it is probable that the virus increases in and is liberated from some tissue within the field of drainage of the mesenteric lymph nodes, either in the intestinal epithelium or in the associated nervous elements. In any case, however, since virus can pass into the faeces and can contaminate the patient's environment, the question arises of the possible portals of entry of the virus into the body and its method of spread from the portal of entry to the central nervous system. Barber,¹⁸ in an account of an outbreak in a school, was impressed by its resemblance to an outbreak of food-poisoning and suggested that the infection might have been by the gastro-intestinal route. A number of observers (cf. Frey¹⁹) have drawn attention to the association of trauma and poliomyelitis, and Howitt,²⁰ Trask and Paul,²¹ and others have pointed out that recently isolated strains of the virus readily infect monkeys if injected intradermally. These findings explain the frequency with which, as reported by Leake,²² children inoculated subcutaneously with partially inactivated virus developed the disease. Thus the skin, if slightly traumatized, may be one point of entry in man. There are other possible portals from which the virus of poliomyelitis may reach the central nervous system. There is already some evidence that instillation into the conjunctival sac may result in infection. Sabin²³ has drawn attention to the tonsil and the possible role of tonsillectomy in providing a portal of entry, and Burnet and Jackson¹⁷ have found that after oral administration the virus can exist at an early stage in the superficial pharyngeal tissues. The findings of these workers after oral administration to *Macacus irus* also serve to confirm the penetration of the

intestinal mucosa by the virus of poliomyelitis, a fact originally demonstrated by Kling, Levaditi, and Lépine.²⁴ How exactly virus reaches the central nervous system from these various possible portals of entry is still not certain. However, the fact that the concentration of virus in the cervical-thoracic vagus and in the sympathetic trunks is high suggests that the autonomic nervous system is responsible for a centripetal spread of the virus.

THE I.L.O. IN THE NEW WORLD

The International Labour Office has been rudely uprooted from the lakeside of Geneva and sent across the Atlantic. It had continued its work very much as usual during the first eight months of war, and was planning its annual conference to be held in June of last year. Then Belgium and Holland were invaded, Italy entered the war, and the barricades on the Swiss frontier symbolized its sudden physical and moral isolation from its chief sources of democratic support. Thanks to generous help by the Canadian Government and McGill University, a new working centre was organized in Montreal, and thither by way of Lisbon, the one open port of exit from the Continent, some fifty members of the staff were after various adventures transferred. No sooner had the organization found its feet in the New World than its director, Mr. John G. Winant, resigned on becoming United States Ambassador to Great Britain. His deputy, Mr. E. J. Phelan, an Irishman, is acting director until the governing body can meet to make a permanent appointment. The resignation of Mr. Winant, however, was the occasion for the reaffirmation by thirty-one States of their whole-hearted support of the I.L.O. These States include Great Britain and all its Dominions, nine European countries (all but one of them occupied, and that one Turkey), the United States, and twelve countries of Central and South America. In a pamphlet entitled *The I.L.O. at Work* a pictorial account is given of the organization in its new environment. Its Economic and Social Security Sections are busily at work on studies of the economic and social background of the changes wrought by the war; the Employment Section is engaged on many problems of wartime labour supply and methods of co-operation between Governments and employers' and workers' organizations; and all concerned are re-establishing the I.L.O. as an international clearing house of information on labour questions, social insurance, and industrial health. It is felt that the I.L.O., in spite of the restrictions within which it has to function, can do a great deal to avert or temper the depression which may seize the world after war is over, and to that end it is preparing itself to help in the orderly demobilization of military forces and defence industries and the setting up of a better social structure in the immediate post-war years.

The annual report for 1940 of the research departments of the College of the Pharmaceutical Society shows that they have managed to maintain their activities in spite of evacuation and depletion of their staff. They are to be heartily congratulated on this achievement. Certain problems of special importance in war have been examined: for example, the influence of cooking on the vitamin content of foods, and the relative antiseptic values of acriflavine and proflavine. In addition the departments have continued their routine testing of vitamins, hormones, and certain galenicals.

TREATMENT OF MAXILLO-FACIAL WOUNDS

The following memorandum on the preliminary treatment of maxillo-facial wounds has been issued by the War Office.

Only first-aid treatment is practicable until the patients arrive at the main dressing station, which may be some hours after the receipt of the wound. Early treatment is directed to saving life, the two main aims being to prevent suffocation and to control haemorrhage. General treatment to prevent shock is given by rest, warmth, and sedatives.

Respiratory Obstruction.—As a result of the injury, loss of control of the tongue and/or displacement of bony tissue may occur to such a degree that the air passages become obstructed. Attention should be paid to the possible presence of foreign bodies—for example, fragments of teeth, dentures, etc.—which should be carefully removed. Posture is of vital importance, and the patient should be placed on the stretcher in the prone or semi-prone position to prevent the tongue falling back. If sitting, or if he is able to walk, the wounded man should do so with his head bent forward and downwards. It is most important that stretcher-bearers should be trained in the transportation of men in the prone or semi-prone position (see *R.A.M.C. Training*, 1935, paras. 73 and 86 (i)).

Haemorrhage.—Correct posture will help to control haemorrhage by keeping the tongue forward. Ligation of visible bleeding vessels may be practicable at the advanced dressing station.

Bandaging.—The ordinary four-tailed bandage should never be used unless applied under the chin, as it is likely to increase the displacement of the fragments by backward pressure. The "barrel" and "Hamilton" types are very suitable and are easily and rapidly applied. A useful external support is elastoplast—a good grip can be obtained in the shaved temporal areas and the scalp left free. In all cases the bandage should be applied under the chin in such a way as to give gentle upward support (see *R.A.M.C. Training*, 1935, para. 589, as amended by Amendments No. 4 of 1939).

Preliminary Operative Treatment.—The main dressing station or the casualty clearing station is the first place where a dental officer will be available, and his co-operation and assistance will be sought in every case (see War Office urgent postal telegram 24/General/554, dated June 8, 1940). After due attention has been given to shock, haemorrhage, and respiration, x-ray examination (both lateral and antero-posterior) should be made at the earliest opportunity, and the following principles of preliminary operative treatment are recommended.

The operation should be carried out as a rule under general anaesthesia, the surgeon and the dental surgeon working together. The throat should be packed with one piece of 6-inch roll gauze during intratracheal anaesthesia until the jaws are ready for intermaxillary wiring, when the packing should be removed. A long stout stitch may usefully be passed through the dorsum of the tongue and the ends secured. This stitch must not be removed until the reflexes have fully returned after the operation. Owing to mobility of the fragments great care is necessary when manipulating any form of gag. Debridement should definitely be more conservative than in the limbs and trunk, and is seldom necessary.

Injuries to Hard Tissues

(a) *Without Loss of Tissue.*—So far as possible accurate apposition of fragments should be carried out. A tooth in the actual line of fracture should be extracted (except when there is only one tooth on the distal fragment and its retention might temporarily assist in control). Fragments carrying teeth should be immobilized by interdental wiring with malleable stainless steel wire. When, in cases of fracture of the mandible, intermaxillary interdental wiring is impossible—for example, where the superior maxilla is edentulous—the principle of maxillary wiring may be adopted. One or more thin stainless steel wires are passed through the alveolar process and looped to furnish fixed points to which the interdentally wired fragments of the mandible can be attached to reduce and immobilize the central fragment. When teeth in the mandible are absent or have been destroyed it may be possible to modify the patient's denture or to

use impression composition or gutta-percha moulded inside the mouth, or in a Kingsley splint, to control the fragments.

(b) *With Loss of Tissue.*—Only the smallest bony fragments which are completely separated from periosteal attachments should be removed. The main fragments should be fixed in normal occlusion with the opposing jaw. If their ends are exposed they should be covered with mucous membrane by the suturing of mucous membrane to mucous membrane or skin. If necessary any jagged ends of exposed bone may be removed to relieve tension. Even if the whole dental region is lost the molar fragments should be held in normal occlusion. Never allow bone fragments (with intervening loss) to fall together, as great deformity and loss of function will result. Surgical wiring of bone fragments is absolutely contraindicated in all compound fractures of the mandible.

Injuries to Soft Tissues (Skin, Muscle, Mucous Membrane)

(a) *Without Loss of Tissue.*—Make a careful primary suture with accurate apposition of skin edges, using fine stitches placed as close to the edge of the wound as possible.

(b) *With Loss of Tissue.*—Only such primary suture of the wound as can be done without any tension or closure of the mouth should be undertaken; thus a loss of one-third of the upper or lower lip, without subjacent fracture, may safely be sutured without detriment to subsequent treatment. It cannot be too strongly impressed upon surgeons that suture of a lip when there is a compound fracture of the mandible should not be attempted until complete control and repositioning of the fragments have been obtained. As a result of the neglect of this rule many cases have been admitted to special centres with an encroachment on the oral opening rendering the subsequent repositioning of the bony fragments extremely difficult. It is far better in these cases to pay all attention to the repositioning of the bone fragments and to leave the suturing of soft tissue and plastic treatment for later attention. In connexion with this, the suture of skin to mucous membrane around the margin of the defect is a procedure of great value in preventing infection and contraction of the soft tissues, either of which will vitiate both hard and soft tissue replacement.

Drainage.—Experience has shown that there is a high frequency of abscess formation after injuries of the lower jaw, and the advisability of providing submandibular drainage at the outset by the insertion of one or more tubes at likely sites should be considered.

Feeding.—The drinking cup with about 3 inches of free rubber tubing is a suitable method of presenting fluid diet well back in the throat.

Mouth Washing.—A solution of sodium bicarbonate is especially recommended as a mouth-wash or for purposes of irrigation in addition to the ordinary antiseptics. The mouth should be irrigated after feeds by means of a Higginson syringe.

Dressings.—Owing to the constant dribbling of saliva in maxillo-facial wounds the dressings are rapidly soaked and frequent changing is necessary. A large jaconet or other waterproof bib should be worn to protect the clothing.

Disposal of Cases.—At the first opportunity the patient should be evacuated to a special maxillo-facial hospital or other hospital where the services of a maxillo-facial team are available.

That the number of practising midwives is diminishing at a time when the calls on the midwifery service are becoming more numerous is an inference to be drawn from the report of the Central Midwives Board for the year ending with March last. There were 64,440 women on the roll of midwives, a net increase of 854 during the twelve months, but only 15,874 had notified their intention to practise during the calendar year 1940, being 1,347 fewer than in 1939 and 1,620 fewer than in 1937, the peak year of the decade. Of the midwives who did make the notification only eleven were untrained "bona-fide" midwives, having been enrolled by virtue of practising before the passing of the Midwives Act. Those entering midwifery practice for the first time during 1940 numbered 1,500. The register of pupil-midwives shows that during that year 2,178 women took the first period of midwifery training and 1,083 the second period. The manner in which the teachers have carried on despite war difficulties is praised in the report; there has been surprisingly little interruption of training.

SERUM RESEARCH IN AUSTRALIA

THE COMMONWEALTH LABORATORIES

[FROM A CORRESPONDENT]

Among the industrial and scientific establishments that have become essential to Australia's war organization are the Commonwealth Serum Laboratories at Royal Park, Melbourne, which are the largest of their kind in the Southern Hemisphere. Since the outbreak of war they have been working at high speed in supplying sera, vaccines, and other biological products for the fighting Services and the civil community, and they now manufacture almost the whole range of biochemical products. For some time the laboratories have been capable of supplying the needs of Australia and its fighting forces over-seas, and recently they were extended to enable them to relieve the United Kingdom of the task of supplying such products to other British possessions bordering the Pacific and Indian Oceans and friendly non-British Powers.

Aim and Work of the Laboratories

The Commonwealth Serum Laboratories were established in the early days of the last war to meet an emergency caused by the cessation of supplies of serum and vaccines from over-seas. They absorbed the earlier Commonwealth Calf Lymph Depot at Royal Park, Melbourne.

A staff of about 300, consisting of graduates in human and veterinary medicine, specially trained in bacteriology and pathology, and highly skilled biochemists, physicists, and botanists, is conducting research into every relevant aspect of bacteriology and immunology. As the growth of medical knowledge opens up new fields of treatment, prevention, and diagnosis, new sera and prophylactic agents are being tested. The livestock population of the laboratories totals many thousands of guinea-pigs, rabbits, mice, rats, horses, cattle, sheep, dogs, donkeys, and bandicoots.

The laboratories are unaffected by constitutional limitations, which restrict Commonwealth action in other phases of public health control in Australia, and in their twenty-five years of existence they have shown a record of steady development, high scientific attainment, and commercial success conspicuous among Government institutions. They now play a part in Australia's national economy for which there is no substitute. The volume of business has steadily increased, and the growing profits are put into a trust account. It is the policy, however, first to pass on to the public the benefit by way of reduced prices for products, and, secondly, to extend the facilities for research into some of the obscure aspects of this branch of medical treatment. Results have been most encouraging, and have proved the wisdom and soundness of this policy.

It has always been the aim of the laboratories to supply only agents of proven value, uniform in potency, and standardized according to the best technique available. The laboratories have been appointed the national centre for the maintenance in Australia of the standards of the Permanent Commission on Biological Standardization of the League of Nations.

Departmental Products

The department responsible for the production of insulin used in the treatment of diabetics has steadily grown, and the amount of insulin now being regularly issued is very large. Commonwealth pituitary extract is now well established among the practising profession as a sound therapeutic agent, and supplies of the Commonwealth subsidiary standard of pituitary are regularly renewed and checked against the international standard. Thyroid tablets are produced and standardized in terms of thyroxine iodine in accordance with the recommendations of the *British Pharmacopoeia*.

Although the local demand for Jennerian calf lymph for vaccination against small-pox is not great, adequate supplies are constantly maintained in a readily available form to meet any possible epidemic emergency. The vaccine department of the

laboratories produces a wide range of vaccines for prevention or treatment of such diseases as cholera and plague, dysentery, gonorrhoea, influenza, whooping-cough, typhoid fever, and coryza, and the streptococcal and staphylococcal infections. In addition this department makes special vaccines to prescription.

Separate departments produce diphtheria and tetanus toxins and also toxoids. The latter are used for the prevention of these diseases in human beings and animals. A special anaerobic department prepares toxin for the production of gas gangrene antitoxin and other sera. In other departments sera are prepared for treatment of many other diseases, including anthrax, dysentery, gonorrhoea, cerebrospinal meningitis, gas gangrene, and pneumonia. Part of the laboratories was recently rebuilt and specially equipped for the investigation of vitamins, and high-grade spectrophotographic and other apparatus are used. Antivenenes for the treatment of snake-bite of the Australian venomous snakes have been the subject of intensive investigation for the last ten years, and antivenene is now available for the most poisonous of the Australian snakes.

A large range of tuberculins is prepared by a special department from human and bovine strains of *M. tuberculosis* for the diagnosis of tuberculosis in human beings and animals. Other preparations from similar organisms are also available. In the allergen department a very large number of special extracts for testing and treatment of hay fever and asthma are prepared.

The media department supplies several hundred different types of bacteriological medium for use by bacteriologists within the Serum Laboratories and in the special departments of hospitals and other institutions throughout Australia. Another special department prepares various agents for the diagnosis of disease as used in the practice of human and veterinary medicine by pathological departments of hospitals, etc. Speaking generally, the work of the laboratories has been a background of scientific research in the fields of bacteriology and biochemistry.

Although, for the last fifteen years, the production of veterinary biological products has been a feature of the work of the laboratories, there has been an extensive development in this direction more recently. The products have been used in greatly increased amounts in all States for the prevention or treatment of disease in domestic animals due to black disease, botulism, tetanus, enterotoxaemia, blackleg, canine distemper, canine tick-poisoning, etc. The care and treatment of many thousands of animals are the responsibility of the veterinary staff.

Activities other than Production

It would be a misconception to regard the Serum Laboratories as an institute solely devoted to the preparation and distribution of biological products. A very large part of the work consists of activities other than production as already indicated. The laboratories do much work as part of the Commonwealth Department of Health, exercising advisory, investigative, and routine functions in a special capacity. In addition, regular annual examinations are held for several grades of officers in the Department. These are compulsory for all of these grades throughout the health service.

For many years, by means of publications of many kinds—independently and in scientific and lay journals—the laboratories have performed an educational service to the community. There is now a considerable and regular issue of articles for publication, embodying the results of original and applied research, which has been extensively developed during recent years.

The Commonwealth Serum Laboratories combine scientific achievement with commercial enterprise in an institution which serves Australia well in time of peace. In time of national emergency it provides a service vital to the civil population and the fighting Services, as well as to those units of the Empire now dependent upon Australia in this respect.

S. Ansbacher (*Science*, 1941, 93, 164), referring to the work of Woods and Fildes on the anti-sulphanilamide activity of *p*-aminobenzoic acid *in vitro*, presents evidence that the latter is one of the factors in the vitamin B complex. According to his experimental evidence, Ansbacher concludes that *p*-aminobenzoic acid is a chromatrichia factor for the rat and a growth-promoting factor for the chick.

ECONOMY IN LIVER EXTRACTS

The Ministry of Health has issued an Order under the Defence Regulations, limiting, as a wartime measure, the use of liver extracts. The Order provides that liver extracts shall be administered to patients suffering from pernicious anaemia or other megalocytic anaemias only and that such administration shall be only by injection. These restrictions will not apply to preparations manufactured before August 31, 1941.

Until now liver for medicinal preparations has been imported, home supplies being used for food purposes. This has meant the use of shipping refrigeration space which is urgently required for other needs. Further, the preparation of extracts of liver to be taken by mouth involves the use of glycerin and alcohol among other substances, and these, as is well known, are in immense demand for munitions. Fortunately, it is possible to achieve economy in the use of liver extracts without patients suffering any hardship. Liver extract is a specific in the treatment of pernicious anaemia and other megalocytic anaemias only, and it has been proved that by far the most effective and economical way of administering it is by injection. It does not, however, have the same specific effect on the other and much more common forms of anaemia, which can be effectively treated in other ways. Patients, therefore, with other forms of anaemia need not suffer, while at the same time ample supplies of liver will be assured for those who really need it.

Local News

ENGLAND AND WALES

An American Hospital in England

On a site in the South of England a complete field hospital is nearing completion with a total floor area of 3,256 feet by 440 feet. It comprises nine wards, a laboratory, a laundry, a recreation centre, a fully equipped kitchen, a pathological laboratory, and accommodation for full medical and nursing staff, who will be drawn entirely from American volunteers. This is an all-American hospital. Roofs, floors, walls, every bolt and screw, and every bit of interior furniture and equipment have been shipped from America as a gift from the American Red Cross and Harvard University, and their enterprise has established something quite new in building practice. The hospital is of timber construction throughout and it was delivered on to the building site in prefabricated sections all ready for rapid assembly. It has been put together under the supervision of Mr. Gwyer of the American P.H.C. Corporation without the aid of plans and detail drawings because these failed to reach this country. It is estimated that, employing thirty men with a knowledge of this system of construction, a hospital of this size could be completely assembled and equipped in less than twenty-five weeks. The hospital incorporates a mobile field unit. Dr. John E. Gordon, professor of preventive medicine and epidemiology at Harvard University, is director of the hospital, and the medical staff have all been supplied by Harvard University.

Bristol Hospitals Fund

Two years ago the voluntary hospitals of Bristol, in a concerted effort to stop the large deficits which appeared annually in their individual balance sheets, launched their own contributory scheme—the Bristol Hospitals Fund. In spite of the war and of gloomy prognostications based on the fact that Bristol already had several independent contributory schemes, the fund has collected £33,000 for hospitals and auxiliary services. Its annual revenue is between £25,000 and £30,000, and its membership—still growing—is 18,000. Still more encouraging is the proposal, announced by Mr. Egbert Cadbury at a recent meeting of the Bristol Hospitals Fund, to start an "intermediate contributory scheme," the admitted object of which is not only to provide for a section of the community whose income falls within certain defined limits, but also to secure some payment for specialist and consultant services in addition to cost of maintenance. The

B.M.A. scale fixing the limit of income for free medical and surgical attention is to be observed by all Bristol voluntary hospitals—that is, the upper limit will be £312 a year for a married person with dependants, £260 for a married person without children, and £208 a year for a single person without dependants. The Bristol Hospital Fund's new scheme is for persons with incomes just above these figures—that is, for married persons with dependants and an income of not more than £416, married persons without dependants and an income of not more than £364, and single persons without dependants with an income up to £260. For a payment of 6d. a week (26s. a year) they will be entitled to full hospital services, including those of specialists and consultants. The scheme will apply to all the voluntary hospitals in Bristol except the Bristol Eye Hospital, where a specially modified scale of fees is payable.

Reports of Societies

PATHOLOGICAL MISCELLANY

About sixty members and guests attended a meeting of the Association of Clinical Pathologists on July 19 at Cambridge, when a number of short communications were made.

Acute Pancreatitis.—Dr. J. F. GASKELL described seven cases of fatal acute pancreatitis in Cambridge between 1932 and 1934. The patients had been in vigorous health, but death occurred within a few hours of onset, in several cases shortly after a full meal. At necropsy, done usually within twenty-four hours, acute haemorrhagic and even necrotic pancreatitis, apparently of ante-mortem origin, was found. No association between the cases could be traced and no significant micro-organisms were found. In one case a man died on the football field, the suggestion being that the head of the pancreas had been squeezed against the spine by another player's knees.

Serum for Transfusion.—Drs. G. A. HARRISON and L. E. R. PICKEN demonstrated the preparation of blood serum for transfusion. Ordinary dry blood bottles were used and about 47% yield of serum was obtained. The resultant serum remained clear at room temperature. Among 102 transfusions pyrexia with rigor occurred once and without rigor four times. On the assumption that the body contained 10 pints of blood and that a haemorrhage of 6 pints was the largest compatible with survival, the maximum amount of serum that could be required even in the worst cases would be 3 pints—that is, half of the volume of blood lost. In most transfusions one bottle of serum had been given. Defibrinated blood was also prepared: 30 c.cm. of glass beads shaken in the blood gave good defibrination. If the blood were not used the serum could be recovered later.

Dr. I. N. GREAVES demonstrated the attractive Cambridge plant for vacuum-freezing drying of serum or plasma. Plasma was dried in the sterile bottle in bulk, or spun so that a readily soluble layer of dried serum adhered to the inner walls of the bottle.

Blood Groups.—Drs. G. L. TAYLOR, R. R. RACE, and Prof. R. A. FISHER showed figures amplifying those published in *Nature* in April, 1940. The proto-Scandinavian abundance of the O phenotype in blood groups as one progressed from South England north to North-West Scotland was clear in the large figures now available from blood transfusion centres, the totals nearing 150,000. For O and A groups the percentage figures for South England were 45 and 43, for North England 48 and 40, for Scotland 52 and 34.

Glandular Fever.—Dr. A. M. BARRETT gave details of technique in deciding titre in the Paul-Bunnell test for glandular fever. Horse red cells, he said, gave a somewhat higher titre than sheep cells. Of 100 normal human sera none agglutinated sheep cells at 1 in 80, 4 gave a titre of 1 in 80 or slightly higher with horse cells. Of 27 cases of glandular fever 17 gave a titre of 1 in 640 or slightly less with sheep cells; 10 had a higher titre. With horse cells 11 gave 1 in 640 or less, and 16 showed

a higher titre. The slight titre in normal sera could be abolished by absorption with Forssman antigen (guinea-pig kidney), whereas ox cells would absorb the true glandular fever haemagglutinin. Dr. S. C. DYKE showed curves of blood counts during glandular fever. The rise in the total white cells might not start for about a week; it reached in the average case about 18,000 per c.mm. at three weeks, dropped to 9,000 at seven weeks, with a temporary secondary rise to 19,000 at about ten weeks. This curve ran parallel to the eosinophil curve, since it was the eosinophil increase that mainly caused the leucocytosis. During the early reduction or absence of eosinophil cells, eosinophil granules might be found in the polymorpho-neutrophils. There was swelling of the eyelids in every case.

Poliomyelitis.—Dr. SINCLAIR MILLER suggested that, as general lymphoid hyperplasia occurred in poliomyelitis and swelling of Peyer's patches was associated with the passage of virus in the faeces, the textbook description of poliomyelitis as an exclusively or predominantly neurotropic virus was insufficient.

Glycosuria.—Dr. F. B. SMITH described glucose-tolerance tests in 57 recruits referred for "glycosuria." Only 1 had diabetes mellitus; 23 had no glycosuria; 29 had renal glycosuria compatible with full activity and good health; and 36 gave a peak response in the tolerance test, with return to normal in one and a half to two hours. Dr. Smith was inclined, for capillary blood, to accept a maximum of 180 to 190 mg., and even 200 mg., per 100 c.cm. if the return to normal took place under two hours.

Tuberculosis.—Dr. C. H. WHITTLE discussed some variations in response to tuberculous infections. Five types were described. Purulent cerebrospinal fluid from acute fatal meningitis in an Indian student showed large numbers of acid-fast bacilli. A boy of 4, afebrile and in good health, was found at operation for hernia to have his peritoneum studded with active tubercles containing acid-fast bacilli. A case of Bazin's disease, one of papulo-necrotic tuberculide, and one of Schaumann's disease were described with biopsies and tuberculin reactions.

Media for Diphtheria Bacilli.—Dr. A. W. DOWNIE described a modified tellurite blood agar medium for diphtheria bacilli. Hedley-Wright agar with 1.0% of Turner's peptone formed the bottom layer of the plate; the top layer of agar contained 5% horse blood and 0.04% potassium tellurite. The addition of 0.75 to 1.0% of Evans bacteriological peptone (or bacto- or difco-proteose peptone) yielded larger *mitis* and *gravis* colonies. Of 488 swabs from new cases, contacts, convalescent and carrier cases, Loeffler plates were positive and tellurite negative in from 2 to 3%, whereas in from 15 to 37% in different groups tellurite plates alone gave positive results.

Haematology.—Dr. L. B. COLE demonstrated a macrocytic anaemia in a baby 4 weeks old, with rapid response to anahaemin. Dr. F. B. SMITH showed 4 cases of ovalocytosis in one family (one patient suffered from pernicious anaemia); and Dr. C. H. WHITTLE sections of benign lymphogranulomatosis in a woman.

Clostridia.—Miss NANCY HAYWARD demonstrated the use of the Nagler reaction for the rapid identification of *Cl. welchii* (Hayward, N. J., *British Medical Journal*, 1941, 1, 811). The reactions of strong and weak toxin-producing strains of *Cl. welchii*, feebly reacting non-*welchii* cultures, and other non-reacting anaerobes were shown both in tubes and on plates. The growth from wound swabs on Nagler plates and on blood plates were compared. In plates containing serum *Cl. welchii* produced a Nagler opacity; if the plate contained a small amount of antitoxin the opacity did not appear. Dr. SCHWABACHER said that *Cl. tertium* would grow as a facultative aerobe. This was often forgotten, despite the work of Hall and Dufforth (*J. Bact.*, 1935, 29, 269). By means of surface viable counts colonies of *Cl. tertium* were found to grow in air, in 5% CO₂, under micro-aerophilic and anaerobic conditions, the intensity of growth increasing in this order. The organism was shown sporing when grown anaerobically and as a Gram-negative bacillus when cultivated in air.

The second American Congress on Obstetrics and Gynaecology will be held at St. Louis, Missouri, from April 6 to 10, 1942. Further information may be obtained from the Chicago office of the Congress, 650, Rush Street.

Describing Hypochlorite Solutions in Treatment of Burns

SIR,—In view of the importance of avoiding confusion in the treatment of burns with hypochlorite solutions, it seems desirable that users of this treatment should take real care in describing the composition of the solutions employed. The dangerous practice of describing a 2.5% dilution of a 1% solution of sodium hypochlorite as "2.5% electrolytic hypochlorite" (Bunyan, *Proc. roy. Soc. Med.*, 1940, 34, 27) has already been criticized by Mr. Lunn (*Journal*, July 26, p. 136) and has been amended by Commander Bunyan (July 5, p. 3) in his proposal to use the term E.S.H. for a 1% solution of electrolytic sodium hypochlorite. But even now it seems undesirable to use the term "5% E.S.H." to mean a solution of 0.05% electrolytic sodium hypochlorite, since the consequences to the patient of the mistaken use of a solution of 100 times the correct strength might be disastrous.

There is further danger in the lack of definition by various authors of the sodium chloride content and pH of their solutions of hypochlorite. These factors may be of clinical importance at least as great as the hypochlorite content, especially when solutions are used such as "milton," which when undiluted is said to contain 16.5% of sodium chloride. All danger of confusion would be avoided if authors were to state early in their papers the content of their stock solution in hypochlorite and in sodium chloride, and the approximate pH. Authors could then refer to dilutions of this solution as "5% of stock solution" and so on, thus admitting of no ambiguity.—I am, etc.,

Neurosis or Psychosis?

SIR,—The perennial debate as to the distinguishability of neuroses and psychoses is certainly wearisome, but it remains fundamental. Unlike Captain Tredgold, experience with the psychiatric disorders of soldiers has impressed on me both the usefulness and the general ease with which a distinction between endogenous and reactive types of depression may be made. There are, it seems to me, two common fallacies which are not always avoided by disputants on this theme. One is in essence the old logical trap which faces one when asked to say how many stones make a heap. If we were to be troubled in this way in physical medicine we might be tempted to doubt the existence of diabetes mellitus as a pathological entity. The other fault frequently committed is a forgetfulness of the fact that psychiatric disorders have a long time-span, frequently extending over the whole of the life. We may be puzzled at any one instant of time to say whether a condition belongs to one or another class, and yet find ourselves in no such difficulty were we able to know the whole past and future life of the patient. Upholders of the belief in a distinction between "neurotic" and "psychotic" types of depression have allowed themselves to be side-tracked by pre-occupation with clinical minutiae, such as the presence or absence of insight. We should rather attempt to evaluate the biological qualities of the illness, as it occurs in its setting of personality make-up and constitution as revealed by family history. If we were to adopt such an attitude, we would no longer be inclined to regard the characteristic phasic disturbance of the manic-depressive and the depressive systems shown almost universally by any sick human being as the polar extremes of the same syndrome.—I am, etc.,

Sutton, Surrey, Aug. 18.

ELIOT SLATER.

Activity of Tuberculosis

SIR,—The clear-cut definition of such useful terms as "activity," "allergy," and "toxæmia" (which are apt to become woolly not only at the edges) is long overdue; I should like, if I may, to accept Dr. Lawrence Roberts's challenge in his letter (*August 16*, p. 245) to define "activity," and set the ball rolling.

I submit that the presence of "activity" is to be deduced only when there are evidences of tissue destruction. The amount of tissue destruction can be measured by means of the sedimentation index and expressed numerically in units: the higher the index the greater the amount of tissue destruction. Healthy young

adult males show indices varying from 0.53 unit to 0.74 unit, with an average of 0.65 unit. Active pulmonary tuberculosis causes indices to rise to anywhere between 0.95 unit and 2.70 units. (The average patient admitted to this sanatorium shows an index of 1.70 units.) Rarely as a result of treatment is the index reduced to less than 1.0 unit; but an index of 1.15 seems to be compatible with good symptomatic health and a full day's work. If in addition the lesions continue to regress the index will improve still further.

If a patient had a T.B.-positive sputum and no evidences of tissue destruction (i.e., an index within normal limits) his bacilli would be entirely saprophytic and perfect symbiosis would exist between them and him. Without any tissue destruction he would be providing them with a home and a culture medium in which to breed. Such a condition obtains with various other organisms, and is therefore presumably theoretically possible with the tubercle bacillus.

But I have yet to meet the man with a positive sputum and a normal index.—I am, etc.,

Vale Royal Abbey, Cheshire, Aug. 17.

GEORGE DAY.

Active Pulmonary Tuberculosis: A Definition

SIR.—In your issue of August 16 (p. 245) Dr. Lawrence Roberts quotes two types of case of pulmonary tuberculosis, and implies that I would class patients in the first type as carriers of the disease. I must disclaim all responsibility for this statement, which is a great surprise to me. I cannot help feeling that Dr. Roberts has misunderstood my meaning, but I do not think that this was my fault, as Dr. Wright, in the same issue, has obviously understood what I wished to convey.

The original purpose of my paper was to make the profession "tubercle-conscious," and it was directed chiefly to those members of the profession who, in the course of their routine work, inevitably meet individuals who are coughing up tubercle bacilli and infecting others. The suggestion was that if those practitioners cared to have sputum examined in every possible case they would meet with some surprising results, and they might well encounter many cases which were infectious and yet which were not suffering from pulmonary tuberculosis. After all, it was only a suggestion, and as such capable of verification, so that there is little point in criticizing the hypothesis until the material which I indicated has been examined.

The discussion has, however, shifted in a direction which I did not foresee, and a definition of active pulmonary tuberculosis is asked for. This is by no means easy. Pulmonary tuberculosis presents itself in an astonishing variety of ways, but for a diagnosis of active disease there must obviously be symptoms and/or signs (in the wide sense, including pathological evidence). The symptoms and signs may be either those of toxæmia or those of a lesion in the lung. Toxæmia, together with evidence of a tuberculous lung lesion, is almost conclusive of active pulmonary tuberculosis. What many people do not recognize is that symptoms and signs of the local lesion are not so conclusive; hæmoptysis, for instance, may continue for years after the lesion has become arrested, usually in such cases being associated with fibrosis and bronchiectasis. The physical signs in the chest are rarely conclusive, although persistent crepitations and pleural friction are usually good evidence. In the same way a single x-ray is universally admitted to be misleading at times, and so, I maintain, is the sputum. I would define active pulmonary tuberculosis as "a tuberculous lesion in the lung which is considered to be responsible for toxæmia or which can be shown on serial skiagrams to be altering." It does not matter in which direction x-ray changes occur, for evidence of improvement is proof that the lesion is, or has recently been, active.

I gather that Dr. Fraenkel advocates the treatment of all sputum-positive cases until they become sputum-negative. This appeals to me most strongly, but how is it to be achieved?—I am, etc.,

London, W.1, Aug. 18.

JAMES MAXWELL.

Chemotherapy in Middle-ear Disease

SIR.—I had assumed that the leading article recently published in your columns had brought to an end the discussion on chemotherapy in acute otitis media. The article by Major C. A. Hutchinson (August 2, p. 159) revives the subject, fortunately, I

think, in view of its practical clinical importance. Dr. Jessiman's opening contribution¹ showed considerable enthusiasm for chemotherapy, though the cases quoted by him appeared to show an infection unusually mild or a diagnosis open to doubt. Later contributors have expressed an appreciation of the value of chemotherapy, but have entered so many caveats and suggested such possibilities that one is left with the impression that while lip-service is paid to the method its value is in fact discounted.

Great emphasis has been placed upon preliminary bacteriological examinations of specimens from the middle ear or nasopharynx. Is this necessary? Is this another case where treatment must wait upon the laboratory? It may be that sulphamylamide, sulphapyridine, and sulphathiazole are not mere specifics for streptococci, pneumococci, and staphylococci, but that each is more polyvalent than its predecessor. Prof. Fleming² recently adduced evidence suggesting the latter possibility. The time should soon arrive when there is general agreement on this important point: it has not yet been reached.

My own practice is to regard the bacteriological examination of these cases as not compensating for the time consumed (nor for the possible expense to the patient). My usual prescription is sulphapyridine in adults, one gramme every four hours as a minimum. This, free fluids, confinement to bed, local palliatives, and appropriate surgery for suppurative when localized are the essentials of treatment.

More important, however, is the suggestion repeatedly made by your correspondents that chemotherapy fogs the clinical picture or masks a mastoiditis (Hutchinson³). I cannot agree that the cases described by the last author are, in fact, cases of masked mastoiditis, unless all cases are to be so described which do not present the old-fashioned and elementary features—pyrexia, mastoid tenderness, and mastoid swelling. Nor has it been shown that chemotherapy was responsible for the course of the disease in the cases quoted by this and other writers. How commonly we saw cases such as those described before the days of chemotherapy! As students we were taught the dangers of antipyretics—relieving symptoms, lowering a perhaps useful rise in temperature, yet leaving the disease untouched. But all the evidence shows that the chemotherapeutic agents under discussion do not act in this way: they are not palliatives, are not antitoxic, but are anti-bacterial.

Chemotherapy may well make otology more difficult; the patient being tided over an acute and spreading infection, the decision to operate for a residual infection may become necessary—a decision requiring judgment, but surely not more than competent otology can provide. And the greater difficulty for the otologist does not counterbalance the advantage to the patient: operation for a localized and not a spreading infection—how desirable elsewhere in the body, how equally desirable in the middle-ear tract!

Altered spheres of activity since the outbreak of war make recent comparisons difficult: in any case the Army should not be a fertile field for mastoid surgery. But I do not forget that in the twelve months before the outbreak of war mastoid operations performed by me were some 40% less than the fairly steady average of the ten preceding years. These twelve months saw chemotherapy (largely sulphamylamide) in extensive use. The lowered incidence of mastoid operations could perhaps in part be explained by the prevalence of streptococci of relatively low virulence (as suggested by T. B. Layton), but chemotherapy was in my opinion an important factor. This practice of chemotherapy and decrease in operations were not accompanied by any increase in complications; the reverse was the case, I believe, but I am writing without access to the records. There occur to me two cases admitted (without previous chemotherapy) of otitis media with meningitis, each showing a turbid C.S.F. with streptococci both in smears and on culture. Both were treated with sulphamylamide; one, occurring early in an acute suppurative otitis media, had no operative treatment of any sort; the other, occurring later in the disease, had a Schwartz mastoid operation; both cleared up completely.

Chemotherapy is of great value in acute suppurative otitis media and its extensions in the early stages and when extension is threatened. It will tend to prevent spread of infection, but it will not cause resolution of a suppuration which has localized. It lessens in no way the need for careful and skilled observation of every case of acute suppurative otitis media; it lessens in no way the truth of the statement that in acute suppurative otitis

media discharge persisting unduly long has a mastoid or nasopharyngeal cause which *must* be cleared up, by operation if necessary, if permanent tympanic damage or serious complications are to be avoided. Failure to perform myringotomy or mastoid operation when indicated is negligence; failure to employ chemotherapy when indicated is also a disservice to the patient.—I am, etc.,

SIR.—Dr. J. B. Jessiman's (March 15, p. 399) article interested me not so much by its optimistic note as by the many patients whose acute otitis media was secondary to scarlet fever. I found that sulphapyridine given in half the dosage recommended brought the temperatures of children suffering from scarlet fever and measles to normal within a few days, and those who were seen early did not develop otitis media. The few who had otalgia when first seen did not have distended drums, and their pains disappeared in twenty-four to forty-eight hours. Similar results were noticed in patients suffering from or likely to suffer from symptoms of otitis media secondary to sinusitis, tonsillitis, endemic parotitis, dental extraction, teething, pertussis, nasopharyngeal operations, and kindred ailments.

I agree with Major C. A. Hutchinson (August 2, p. 159) that too much reliance should not be placed on the sulphonamides, but not that sulphapyridine should be replaced by sulphanilamide in streptococcal infections. The dosage and variety of sulphonamide should depend on the age, sex, idiosyncrasy, and complaint of the patient, and the course of the condition.

A man aged 35 was suffering from acute pain in the right ear. This was associated with right antral, sphenoidal, and tonsillar infection. The drum was distended and oedematous. Myringotomy immediately relieved the pain: 0.5 gramme of sulphapyridine was given three times a day for three days. Clear blood-stained serum, usually associated with streptococcal infection, escaped from the curved myringotomy incision. No secondary infection occurred with pneumococci or staphylococci and the drum was dry on the fourth day. He returned to work in ten days and has had no return of symptoms.

The following three cases may also be of interest.

A boy aged 2 years, with a history of suppurative otitis media for fourteen days, had creamy pus coming from the right ear and cloudy pus from the left. A quarter of a 0.5-gramme tablet of sulphapyridine was given three times a day for a week, half a tablet was given twice a day for the second week, and a quarter tablet for the third and fourth weeks. The left ear was dry at the end of the second week and the right at the end of the fourth week.

A boy aged 2 years had had spasmodic torticollis on the left side of three months' duration. There were injection, thickening, and loss of light reflex of the left drum. This was associated with loss of appetite and poor health. There was also a left antral infection and chronic rhinorrhoea. A quarter of a tablet was given three times a day for the first week and twice daily for the second and third weeks. The rhinorrhoea had now ceased, the appetite returned, and the thickened and retracted drum was less injected. The spasmodic torticollis was now only pronounced when on his mother's right arm. Nebulae ephedrin. (ephedrine grain 1/4, liq. paraffin ad 1 oz.) with guttae ac. carbolic were continued for two months, when recovery took place.

A youth aged 18 had had a discharging ear for three months. Offensive cholesteatomatous material was removed when syringed: 0.5 gramme of sulphapyridine was given three times a day for three weeks, when the ear was dry and a clean healthy perforation remained.—I am, etc.,

Burley, Leeds, August 11.

L. C. LODGE.

Severe Reaction after Sulphapyridine

SIR.—Quite apart from the fact that a definite diagnosis has not been made in the case here recorded, the interesting feature is the intense reaction following reinstitution of therapy with sulphapyridine. The presumption is, of course, that the patient has become sensitized to it.

The patient, a woman aged 60, had eight weeks ago become suddenly ill with malaise and fever. On the second day of her

illness she became covered with a scarlatiniform rash, which disappeared after twenty-four hours. She was febrile at this time, but there was no sore throat. The fever continued, and therapy with sulphapyridine was started. She was given 0.5 gramme at four-hourly intervals for six days—a total of 18 grammes. Fever still persisted, and after a lapse of three days treatment with sulphathiazole was instituted. She was given three tablets every four hours for three days. During the time she was taking sulphapyridine she felt very ill and vomited three to four times daily. Sulphathiazole therapy produced similar symptoms, but they were not so bad. At the end of this time—that is, four weeks ago—the patient was still febrile and has remained so ever since.

During the last week she has been given pentnucleotide 10 c.cm. every other day for four doses, in the hope that it might improve the polymorphonuclear count (see below). After the fourth dose I thought that another course of sulphapyridine might help to get rid of the fever. The patient felt well at 7 a.m.; temperature 99°. One tablet was given at 8 a.m. At 8.30 a.m. she vomited and felt very ill. At 9 a.m. she had a rigor and another at 10 a.m. Temperature rose to 104°. No more sulphapyridine was given, and her condition gradually improved during the day.

On examination the only physical sign she presented was an indescribable bruit—pericardial—which occurred in diastole over the pulmonary area. Blood culture and the urine were sterile. Agglutination reactions, repeated twice, for *B. typhosus*, paratyphoid A and B, and *Br. abortus* were negative. A blood count showed 30% haemoglobin, 1,700,000 red cells per 100 c.cm., colour index 0.9. The white cells numbered 2,100; lymphocytes 79%, polymorphs 21%.

The patient's past history is of interest. At birth she is said to have been a "blue baby," which is a possible explanation of the heart murmur. Three years ago she had a septic finger followed by a staphylococcal septicaemia, from which she recovered with difficulty. She had lobar pneumonia one year ago, when she responded well to sulphapyridine.—I am, etc.,

Tenbury Wells, July 19.

J. A. BURNETT, M.R.C.S.

Abortus Fever and Sulphapyridine

SIR.—In your issue of August 9 (p. 210) Dr. J. Whittingdale writes of the treatment of a case of abortus fever with sulphapyridine. If I interpret the case report correctly, the patient had approximately fourteen days of fever, on the last two of which he was given sulphapyridine. Since then Dr. Whittingdale has noted an afebrile phase of about ten days before sitting down to pen an enthusiastic eulogy of "our newest bactericide," which tempts him into the unequivocal and forthright title for his letter of "*Brucella abortus* Infection responds to Sulphapyridine" (I presume that is his own choice).

It may well be, of course, that the patient concerned has remained afebrile since Dr. Whittingdale wrote his letter, but it is surely misleading to record as an apparent cure, after so short a time of observation, a case of a disease which is notorious for its intermissions and relapses.

Our opportunities for studying this interesting disease at first hand are necessarily limited. A recent case of my own has been under observation in all for rather over one hundred days. In that time there have been three febrile phases lasting approximately 10, 14, and 4 days, but the intermission periods which have punctuated these have been 20 and 28 days, and, up to the present time, a further 28 days have passed since the last phase. I am not yet able to say that a point of cure has been reached. The illness has been entirely symptomless except for sweats and temperature and the usual concomitant features during the bouts of fever. There have been no joint or muscle pains and no splenic enlargement. The agglutination titre for *Brucella abortus* was 1:500. Sulphapyridine was given during the second and third febrile phases in doses of 0.5 gramme four-hourly except when the patient was asleep. As to its effect one can only speculate. The course of the fever in the second stage did not show any material difference from that of the first, in which sulphapyridine was not used, and actually the second stage lasted longer. Treatment in the second stage did not prevent a further relapse after twenty-eight days, and, though the subsequent recurrence of temperature was not prolonged, that fact cannot necessarily be attributed to sulphapyridine, which in this case certainly failed to achieve any dramatic result.

comparable to the effect in other conditions—for example, pneumonia. Abortus fever is so capricious in its behaviour that one cannot with certainty say how much its course is influenced by treatment or how much by the natural rise and fall of the infection itself.

One point of interest is the possible effect of sulphapyridine on the blood picture, which is normally leucopenic in this condition. My own case showed 3,800 white cells per c.mm. after the first course of sulphapyridine, with polymorphs 40% and lymphocytes 51%. If prolonged treatment with sulphapyridine should become necessary in this type of case, the double strain on the granulocytes—one from the disease and the other from treatment—must be considered.

Most of us in general practice must see from time to time, especially in children, febrile illnesses some of which are unrecognized cases of abortus fever. The temptation to give sulphapyridine to pyrexias of doubtful origin is obviously great, and at times may seem justified by results. It is impracticable to take blood specimens either for counts or for agglutination tests in all cases. We thus do a double disservice—first to the patient in treating, without adequate control, pyrexia with leucocytosis in the same way as pyrexia with leucopenia; and, secondly, to both the patient and scientific truth (also important) in obscuring the nature of a pyrexia before establishing a diagnosis. Indiscriminate use of sulphanilamide, sulphapyridine, and sulphathiazole is as great a fault as masking the acute abdomen with morphine.

May I add that I shall be happy to hear at some future date that Dr. Whittingdale's case has not belied his enthusiasm for "our new weapon," or that the "target" which he has shot to pieces has not suddenly popped up again. The more recorded experiences of abortus fever and the treatment thereof with sulphapyridine the better.—I am, etc.,

Boston, Lincs, Aug. 13.

J. H. F. PANKHURST, M.D., D.P.H.

Haemorrhage in Sulphonamide Therapy

SIR.—I was interested to read Dr. Crawley's memorandum (August 2, p. 160), in which he described intestinal haemorrhage complicating sulphonamide therapy in two cases of meningococcal meningitis.

In his first case, before being certain that the drug was the cause of the symptom, the question of haemorrhage into the adrenals should, I think, be considered. Nelson Carey (*Ann. intern. Med.*, 1940, 13, 1740) calls attention to this complication of septicaemia, and states that it is most often associated with the meningococcus. He states also that the condition usually occurs in children and may be recognized by collapse, cyanosis, accelerated respiratory rate, low blood pressure, vomiting, and purpura during the course of the initial illness. The leucocyte count is high. Heinle (*Arch. intern. Med.*, 1939, 63, 575) reports massive haemorrhage into the adrenals in patients dying of acute meningococcal septicaemia, who may also have haematemesis, melaena, and extensive purpura. In Dr. Crawley's first case adrenal haemorrhage rather than the drug seems, I think, to have been a more likely cause of the melaena and sudden death. It would be most interesting to know if a post-mortem was performed and whether there were any blood-pressure readings.

In his second case, although the evidence is far more suggestive of the drug's causing the melaena, another possible explanation is an acute peptic ulcer occurring during the course of the infection. Although I have on occasion seen haematuria as a complication of the sulphonamides, I have not come across melaena during extensive use of the drugs in both meningococcal and other cases in the last two years.—I am, etc.,

AUG. 6.

Medical Planning

SIR.—May I be allowed to congratulate Dr. Douglas Boyd on his letter (August 2, p. 179). His statement on the attitude of the profession towards medical politics tallies exactly with my own. The crying need of the moment is not a blue-print of the future, which not even the Government can foresee, but to achieve unity among ourselves. There is great uneasiness among the rank and file, but instead of looking to the B.M.A. for a lead each man is trying to provide for his own security—G.P.s

are hurriedly taking up factory appointments and consultants are seeking addresses elsewhere "for the convenience of their patients who have been evacuated." The *saave-qui-peut* momentum is increasing and will become a Gadarene stampede when the men now on service come home.

The movement for unity should have preceded the Planning Commission, and it may be now too late, but therein lies the only hope of averting the disruption of the profession. No confidence is placed in the assurance that the findings of the Commission will be submitted to the Divisions for final approval, the general feeling being that whatever they may be they will have to be accepted as the quickest way out of an intolerable state of things, and that any disagreement will receive scant consideration. At present the B.M.A. has no adequate machinery for finding out what the wishes of its own constituents are, even if it wished to, and there is a considerable body of medical opinion altogether outside the fold.

If the B.M.A. wishes to put its own house in order before the deluge, it should begin by establishing close contact with the periphery, and this can only be done, in my opinion, through whole-time paid officials in each Division or group of Divisions. The average G.P. has no time, and is generally too tired, to devote his leisure to accounts and clerical work, still less to travel considerable distances to attend arid business meetings. A paid representative would take all this off him, would arrange short *ad hoc* meetings, or would ascertain the views of his Division by personal visits. After which he should be in a position to keep his Division in constant touch with headquarters by frequent visits to London—say, once a month. In this way provincial members at least would get a great deal more for their money than a building in London which few contrive to visit more than once or twice in their careers. Personal contact with a representative would go a long way towards recovering the lost prestige of the B.M.A. among members and non-members. Under existing arrangements a Divisional secretary has few opportunities of making such contacts.

Another urgent requirement is for an effective voice to be found for dissentient opinion. Among 36,000 medical men there is bound to be opposition to any policy, and it is no answer to say that the Divisional Representative can come to London under the existing arrangements to give tongue to it. It is not at all easy to find a representative in a small Division—few men are accustomed to public speaking, many lack self-confidence, and all lack time. Nevertheless, their dissent may be both strong and reasonable. Such men drift first into sullenness, then into apathy, and lastly into defection. Can the B.M.A. envisage this situation with complacency?

Desperate needs call for desperate measures. Can the B.M.A. realize that the need is desperate and urgent? Or will it still continue to act as though the G.P. were not capable of knowing which side his bread was buttered? Mere additions to an already top-heavy Commission will not meet the case.—I am, etc.,

C. J. STOCKER,
Lieut.-Col., I.M.S. (ret.).

Cannon Hill, Lancaster, Aug. 4

The National Loaf

SIR.—Dr. Griffith Evans (August 9, p. 112) is hopelessly at sea in regard to the subject under discussion. He is evidently mixing up the national wheatmeal loaf, which is not fortified, and against which I have never expressed an adverse opinion, with the white loaf, which I believe in some parts of the country is fortified with one vitamin and nothing else. It is the unfortified loaf which is rich in vitamins, etc., and not the fortified loaf. From the letter of your correspondent it would appear as though my criticism had been concerned with the national wheatmeal loaf. I never said that the loaf was fortified with calcium alone. It is certainly not a fact, as stated by your correspondent, that "calcium is added in the form of phosphates." Calcium is not added in any form to the fortified loaf; but so far as the original proposal in regard to this substance is concerned I should like to refer him to the various memoranda of the M.R.C.

Bad teeth are common among all sections of the community, but they certainly have nothing to do with calcium deficiency (see our paper in this *Journal*). In regard to vitamin D, etc., the point is this. The only evidence which is said to point to a calcium deficiency is a rare disease called "osteoporosis." This condition is now generally recognized to be due to vitamin D

deficiency. It follows, therefore, that there is a vitamin D deficiency somewhere in our diet. My criticism solely concerned the original proposal to add calcium to flour. We know now, from a recent statement by Major Lloyd George, that the fortified loaf does not contain added calcium. I have now no adverse comments to make on the bread policy of the Government.—I am, etc.,

Liverpool, Aug. 15.

I. HARRIS.

Obituary

C. A. SCOTT RIDOUT, M.S., F.R.C.S.

The passing of the distinguished Portsmouth surgeon, Mr. Charles Archibald Scott Ridout, has cast a gloom over all who knew him.

He was born in 1875 at the Royal Naval Hospital, Stonehouse, Plymouth; his father, Staff-Surgeon Charles Lyon Ridout, R.N., was on the staff there, and later served in H.M.S. *Tourmaline*, East Indies, and died at Mauritius of malarial fever. His mother was Ada Purley, daughter of Archibald Scott of Halifax, Nova Scotia. When a small boy he began his education at Plymouth College, and from there he went on in 1887 to Sherborne School, where he remained six years; the environment of this school remained his Mecca to the end of his life. In 1894 he proceeded to St. Bartholomew's, and qualified in 1899, obtaining the M.S.Lond. in 1903, and the F.R.C.S. in 1904. Several house appointments followed—at Bart's, North Stafford Infirmary, and the Royal Hospital at Portsmouth. He was destined to become a surgeon and a hospital man, eventually holding the position of senior surgeon at the Royal Portsmouth Hospital and the Portsmouth and Southern Counties Eye and Ear Hospital. At the latter hospital, which he dearly loved, he accomplished some of his best work over a period of thirty-three years. His influence for its extension was all-prevailing, and so it was meet that his memorial service, which was very largely attended, should have been held at the Cathedral of old Portsmouth, in the immediate vicinity of that hospital. He also held other surgical appointments, and was president of the Laryngological Section of the Royal Society of Medicine in 1937-9, and a vice-president of the Section of Laryngology and Otology of the British Medical Association in 1924. He was a strong advocate of the B.M.A., serving as secretary of the Portsmouth Division and president of the Southern Branch, and local general secretary for the Annual Meeting at Portsmouth in 1923.

Surgeon Rear-Admiral R. J. McKEOWN, O.B.E., R.N. (ret.), writes:

In the midst of such a strenuous life it might reasonably be thought he had few spare moments, but Charles Ridout readily accepted the chairmanship of the Local Medical War Committee, Portsmouth, in March, 1939, and carried through with success the scheme for the "Protection of Practices," which safeguards the practices of his colleagues who have volunteered or been called up for the defence Forces. He organized two clinical meetings yearly, which were always successful and much appreciated by his colleagues. He was extremely patriotic, and during the last war served as surgical specialist and surgical divisional officer, with the rank of major, R.A.M.C., in the 29th Stationary Hospital at Salonika (1916-17), and in Italy (1917-19). His principal hobbies were those which might be expected of a man with his vigorous mind—motoring, fishing in Scotland, and rugger; in fact, nowhere was he happier than when running up and down the touchline encouraging the first XV, in which his eldest son played, at his old school, and for many years he attended the university and international matches at Twickenham.

Nature bestowed on him some of her finest gifts: a keen intellect, great powers of physical endurance, and infinite patience.

In the operating theatre, perhaps, was to see him at his best, so ably exercising his masterly skill with the lightest touch, never perturbed by any unforeseen complication (for which the remedy was immediately forthcoming); sympathy and kindness for one and all, especially for his child patients and their anxious parents. No wonder that his name became a household word with rich and poor alike; and so, when his health began to fail some months ago, his many friends were gravely anxious and distressed. But he carried on as usual until an operation became imperative in June last, from which he made a hopeful recovery, and his complete restoration was anticipated, but, alas! a fatal relapse frustrated these hopes. On the domestic side of his life he was a devoted husband and good father, taking the liveliest interest in the careers of his children—one of his sons a soldier who was present at Dunkirk; his second son, a surgeon lieutenant R.N.V.R., present at the naval engagement at Narvik; and a daughter now following in her father's footsteps as a medical student. He was buried at Sherborne after cremation at Southampton, and to his widow and children is extended the deepest sympathy. Truly it may be said of Charles Ridout, "Well done, thou good and faithful servant; enter into rest after toil."

J. JAMESON EVANS, M.D., F.R.C.S.

We regret to announce the death of Mr. J. Jameson Evans on August 13 at Aberdovey. He was for many years surgeon to the Birmingham and Midland Eye Hospital and had been president of the Midland Ophthalmological Society and the Midland Medical Society.

Born at Carmarthen in 1871, John Jameson Evans was educated at St. David's College School, Lampeter, and Queen Elizabeth's Grammar School, Carmarthen, and after a distinguished student career at the University of Edinburgh, graduated M.B. and C.M. with honours in 1892. He took the M.R.C.S. and L.R.C.P. diplomas in 1897, the F.R.C.S.Eng. in 1899, and the M.D. degree of Birmingham University in 1903. His first appointment was as house-surgeon to the Carmarthenshire Infirmary; in 1897 he began his long association with the Birmingham and Midland Eye Hospital as resident surgical officer. After three years he was appointed honorary ophthalmic surgeon, and continued to serve in that capacity till 1934, when he became consulting surgeon.

Mr. Jameson Evans had been for many years consulting ophthalmic surgeon to the Birmingham General Dispensary and ophthalmic surgeon to the Royal Institution for the Blind, Edgbaston, to the Hallam Hospital, West Bromwich, and to the Bromsgrove Hospital. He was Middlemore lecturer in 1899. During the last war he served as ophthalmic surgeon to the 1st and 2nd Birmingham War Hospitals. At the Annual Meeting of the British Medical Association in Birmingham in 1911 he held office as honorary secretary of the Section of Ophthalmology, and at the Centenary Meeting in London in 1932 he was vice-president of the same Section. He was the author of *Notes on Ophthalmology for Students* and contributed articles on diseases of the eye to this and other journals. He had been vice-president of the Ophthalmological Society of the United Kingdom. He served on the council of the Oxford Ophthalmological Congress, of which he was a foundation member, for nineteen years, and held the position of lecturer in ophthalmology in the University of Birmingham for twenty-five years.

Mr. Jameson Evans leaves a widow, the second daughter of the late Principal Edwards of Aberystwyth, and two sons, both of whom are engaged in medical practice.

Mr. HARRISON BUTLER writes:

The unexpected death of Mr. J. Jameson Evans after a very short illness has come as a blow to his colleagues in Birmingham and to his many friends and patients. It was my privilege to work with him for eighteen years as a colleague on the staff of the Birmingham Eye Hospital, and naturally I learned to know him very well, to respect him, and to love him. We sat on the same day at adjoining desks, and became thoroughly acquainted with each other's views and work. I look back upon those years as among the happiest of my life. Never was there the slightest semblance of friction between us, and never have I

seen Evans lose his temper or utter a cross word. He always had a happy smile and a pleasant witicism for everybody. His courteous treatment of the patients was an example to all. Even during the last war, when three out of the six surgeons were on active service and we were always short of good house-surgeons, he was unruffled, efficient, and helpful. Pathology was Evans's strong suit. For many years in his early days at the hospital he made himself responsible for this branch of the work, and he became quite enthusiastic over any unusual condition. He was an outstanding ophthalmoscopist and his judgement was unerring. Although he never seemed to read much, he always knew all about current literature. I think that his active brain soaked up facts and theories with the facility of a sponge; he learned without difficulty, and retained all the knowledge that he acquired. His death leaves a gap that cannot be filled. His friends called him "Sunny Jim," and that exactly describes the man.

EPIDEMIOLOGICAL NOTES

Infectious Diseases for the Week

The returns for England and Wales show a substantial decline in the incidence of the common infectious diseases. The numbers of notifications of whooping-cough, measles, diphtheria, and scarlet fever were 638, 246, 94, and 32 fewer, respectively, than in the preceding week. In Scotland an increase has been recorded, and the cases of scarlet fever, diphtheria, and whooping-cough increased by 8, 78, and 18 respectively.

Typhoid and Paratyphoid Fevers

The increase in the number of cases of typhoid in England and Wales, 34 as compared with 24 in the previous week, was due to isolated cases over a wide area: eight more counties were involved than in the past week. The decline of the local outbreak in Cheshire and Lancashire—25 and 96 cases were reported from these counties as compared with 43 and 133 of a week ago—was responsible for the large decrease in the number of notifications of paratyphoid. The incidence remains high in Liverpool C.B., and, with 70 cases, this city accounts for over one-third of the total for the country. In Scotland only 13 cases were recorded, against 33 of the previous week.

Dysentery

The outbreak in Brecknock M.B. has apparently subsided, only 1 case being reported this week against 69 last week. The experience of three counties accounted for over one-half of the total cases reported in England and Wales; the remainder were distributed over twenty counties. The principal outbreaks were those of Essex, 13, of which 12 were reported from Colchester M.B.; Lancaster, 19, of which 11 were contributed by Blackburn R.D.; Suffolk East, where the whole of the 37 cases occurred in Leiston cum Sizewell U.D. In Scotland 52 cases occurred during the week, the largest outbreaks being those of Lanark County 13, Aberdeen County 9, and the Burghs of Dundee 10 and Glasgow 8.

Cerebrospinal Fever

Cerebrospinal fever showed a slight increase during the week; 19 more cases were notified in England and Wales than in the preceding week. The disease was widespread, over thirty counties reporting its presence. The largest outbreaks were those of Lancaster 26, West Riding of Yorkshire 20, and London 12. An increase of 5 was reported from Scotland. Glasgow, with 15 cases, accounted for over one-third of the total cases notified.

Acute Poliomyelitis

Although the number of cases reported in England and Wales was only 1 less than in the preceding week, only ten counties were involved as compared with seventeen counties in the previous week. The counties of Berkshire and Buckinghamshire, with 8 cases each, were responsible for over half the cases recorded in the country. The opening of the elementary and secondary schools in a large area of South Buckinghamshire has been postponed until further notice because of the outbreak. Individual districts with multiple cases were: Berkshire (Maidenhead M.B. 6); Buckinghamshire (Slough M.B. 3, Eton R.D. 3, Wycombe R.D. 2); Lincolnshire (N. Kesteven R.D. 2). Nine cases were reported from Scotland, an increase of 2 upon last week's number. Multiple cases were notified from Edinburgh 3, Lanark County 2, and Glasgow 2.

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended August 2.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included), (b) London (administrative county), (c) Scotland, (d) Eire, (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London), (b) London (administrative county), (c) The 16 principal towns in Scotland, (d) The 13 principal towns in Eire, (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

* Includes paratyphoid A and B for Eire and Northern Ireland.

† Includes primary form in figures for England and Wales, London (administrative county), and Northern Ireland.

‡ Owing to evacuation schemes and other movements of population, the birth and death rates for Northern Ireland are no longer available.

The Services

NAVAL AWARD

The O.B.E. has been awarded to Surgeon Commander Edward Hefferman, R.N., for bravery and devotion to duty in boarding a burning merchantman during an enemy air attack.

ARMY AWARD

The Military Cross has been awarded to Captain Robert Norman Lees, R.A.M.C., in recognition of gallant and distinguished services in the Middle East.

CASUALTIES IN THE MEDICAL SERVICES

ROYAL ARMY MEDICAL CORPS

Prisoners of War

War Substantive Captain Wilfred R. Crowe.
War Substantive Captain Nicolas Shtetinin Seaford.
War Substantive Captain Malcolm Montgomery Wallis.
War Substantive Captain Richard Mallorie Wiltshire.
Lieut. Archibald Leman Cochrane.

Medical News

Dried separated milk powder, rich in protein and therefore of special value for children, may now be purchased in bulk from the Ministry of Food by school canteens, residential schools, and hostels, and Circular 1561 of the Board of Education explains how this should be done. The allowance of the powder is 1 oz. a day for each child. It is also announced that industrial undertakings which supply milk as a beverage to their workers should apply to local Food Offices for permits to continue this practice, as provision is to be made in the milk distribution scheme for the supply of milk for this purpose.

The Privy Council has appointed Dr. G. Roche Lynch lecturer in chemical pathology, St. Mary's Hospital, and senior official analyst to the Home Office, to be present at the examinations held by the Pharmaceutical Society.

A medal was recently presented to Dr. Maurice Roch by the Société Médicale de Genève on the occasion of the twentieth anniversary of his professorship of clinical medicine at Geneva.

Dr. J. Alejandro Téliier has been appointed Director-General of Health in Bolivia.

Universities and Colleges

UNIVERSITY OF CAMBRIDGE

At a Congregation held on August 2 the following medical and surgical degrees were conferred:

M.D.—*K. Vigors Earle, E. D. Hoare, R. H. Dobbs.
M.B., B.Chir.—*R. M. Archer, *E. D. Barlow, *D. V. Bateman, *R. I. S. Bayliss, *S. L. Binderman, *P. T. Boyle, *K. F. C. Brown, *E. D. H. Cowen, *D. Currie, B. Dansie, *R. Daley, *J. O. W. Dick, *W. M. M. Douglass, *J. R. Ellis, *R. M. Evans, J. Foley, *R. B. Franks, *R. E. A. S. Hansen, *D. V. Harris, *A. Holmes-Smith, *F. H. Howarth, *E. W. Hyde, G. T. James, *R. K. I. Kennedy, *E. F. Laidlaw, J. M. Lipscomb, *J. F. Lucey, *G. M. Lunn, *F. N. Macnamara, *O. D. Macnamara, *A. E. de la Tour Mallett, *R. Martlew, G. A. Mott, J. M. Mungavin, *H. H. Nixon, *J. F. North, *M. S. M. Palmer, *G. H. Parkinson, *A. G. E. Pearse, *John Perrin, *M. T. Pheils, *G. E. Pinkerton, G. K. Riddoch, *K. B. Rooke, *R. D. Scott, C. G. R. Sell, *A. W. Simmins, *A. G. Stansfield, *D. E. Thompson, *A. J. H. Tomlinson, *J. G. Thurston, *A. B. Unwin, *A. H. Widdup, *J. M. Willcox, *A. B. Kinnier Wilson, C. H. Wood, *W. B. Young.

* By proxy.

UNIVERSITY OF LONDON

King's College Hospital Medical School

Upon the results of recent examinations, awards have been made as follows:

Senior Scholarship for Clinical Studies: R. A. Moir, King's College Hospital Medical School.

Anatomy and Physiology Scholarship: J. R. M. Miller, King's College, London.

Pathology Exhibition: V. H. Wheble, Brasenose College, Oxford.

Science Scholarship: P. C. Harris, St. Olave's Grammar School, London, S.E.

UNIVERSITY OF GLASGOW

A series of eight postgraduate meetings will be held in the Tennent Institute of Ophthalmology on Wednesdays from September 10 to October 29 at 8 p.m. The subjects of the addresses will include: postgraduate tuition in ophthalmology, the making of the ophthalmic specialist, ophthalmic practice in retrospect, the future of ophthalmic practice, pros and cons in ophthalmic therapeutics, ophthalmology in the law courts, and the problem of the nearly blind. There will be opportunity for informal discussion.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, W.C.1.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated.

Authors desiring REPRINTS of their articles must communicate with the Secretary, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors over-seas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

ADVERTISEMENTS should be addressed to the Advertisement Manager (hours 9 a.m. to 5 p.m.). Orders for copies of the *Journal* and subscriptions should be addressed to the Secretary.

TELEPHONE No.—B.M.A. and B.M.J.: EUSTON 2111.

TELEGRAPHIC ADDRESSES.—EDITOR, *Aitiology Westcent*, London; SECRETARY, *Medisecra Westcent*, London.

B.M.A. SCOTTISH OFFICE: 7, Drumsheugh Gardens, Edinburgh.

QUERIES AND ANSWERS

Timepiece for Blind Person

Mr. N. BISHOP HARMAN writes in reply to "Inquirer." (August 16, p. 254): The most pleasant timepiece for the blind is a "repeater," either a carriage clock or a watch. Pressure on the button on the case causes a striking of the hour and half-hour. There are special watches made for the blind, with "hunter" cases, and face with raised metal figures and strong hands. The time is told by feeling the face. If cost be a consideration, the simplest plan is to get a five-shilling clock, remove the glass front, and put small blobs of sealing-wax on III, VI, IX, and XII. Anyone can tell the time by feeling the position of the hands of the clock, and without any sight.

E. H. C. writes: A relation of mine, blind from his youth, used an ordinary "hunter" watch with the glass removed, and he could tell the time by feeling the hands. Possibly, however, as the lady has only recently become blind, she may have difficulty in acquiring sufficient delicacy of touch for the employment of this method. If means permit, the obvious solution is the purchase of a watch or a small travelling clock that repeats hours, quarter-hours, and minutes, but I fancy the cost of such an article would be in the neighbourhood of £100. It might be worth advertising for a second-hand one.

LETTERS, NOTES, ETC.

Medical Unit for Ethiopia

Dr. ANDREW MORLAND writes: In response to a request from the British Administration in Ethiopia, the Friends Ambulance Unit is shortly sending to that country a medical unit of forty men. The need for medical personnel in Ethiopia is greater than ever and it is anticipated that the F.A.U. will assist in the more elementary forms of medical treatment. It is also thought likely that they will be called upon to train native dressers in this work. The work of the unit will be under the supervision of the Director of Medical Services, but its value would be greatly increased by the inclusion of qualified doctors. Their presence would also be cordially welcomed by the Administration as well as by the native of Ethiopia, whose medical needs have been so greatly accentuated by the recent fighting. Any medical man wishing to offer his services in this direction should write to the Secretary, F.A.U. 4, Gordon Square, London, W.C.1.

Convalescent Poliomyelitis Serum

Drs. SINCLAIR MILLER and STANLEY WRAY write from Duchy House Clinic, Harrogate: We have available a moderate supply of convalescent poliomyelitis serum for use in conjunction with sulphapyridine, and would be willing to forward a limited quantity on request.

THE FUTURE OF MEDICAL EDUCATION AS SEEN BY A TEACHER

BY

JOHN A. RYLE, M.D.

*Regius Professor of Physic in the University of Cambridge: Consulting Physician to Guy's Hospital;
Consultant Adviser in Medicine in the Emergency Medical Service*

Without an accurate acquaintance with the visible and tangible properties of things our conceptions must be erroneous, our inferences fallacious, and our operations unsuccessful. "The education of the senses neglected, all after-education partakes of a drowsiness, a haziness, an insufficiency, which it is impossible to cure." Indeed, if we consider it, we shall find that exhaustive observation is an element in all great success. (From Herbert Spencer's *Essay on Education*.)

I

At a time when planning is much in the air, but the war and the vast uncertainties of the future conspire to give to all Utopian castles a more than usually aerial quality, the Editor has invited a statement of ideas on the future of medical education. At the moment we cannot begin to visualize the kind of foundations upon which we shall have to build. The physical, social, and economic structures of our post-war world are beyond imagining. Ideas and hopes must therefore be accepted as such and not regarded as fixed projects. Discussion and inquiry must be fostered. Individual opinions in such a time, although freely expressed, may later need to bow to change or circumstance.

We can, nevertheless, start with the thesis that medical education stands much in need of reforms, and that all concerned for it, both old and young, are willing to become reformers in aid of this particular contribution to our new order. On certain main points, such as the overcrowding of the curriculum, there will be full agreement, and none will dispute that the aims of medical education should include on the one hand the training of sound and practical doctors and on the other the maintenance of high cultural and scientific standards. If there is one thing which medicine has shown a tendency to sacrifice in return for the rapid contributions of the sciences to its instruction and practice, it is perhaps its position as a cultural profession. Its philosophy has not kept pace with technical achievement.

Let us briefly state the problem which confronts us in the form of a question. How shall the medical education of the future, without further complications of or additions to the curriculum, provide a better scientific and general training for the student and ensure a more organized and integrated approach to the clinical subjects and, in place of accumulations of memorized but poorly correlated detail, a wider appreciation of first principles? How in the process shall it help to develop a breed of doctors better blessed with humanity and judgment, with simultaneous gain rather than loss to their scientific sense?

II. The Phases of Education

The teacher in the wards receives the product of a previous education in the schools and the laboratories, and, while fully conscious of shortcomings in his own department of learning, may justly feel entitled to criticize some

of the results of preliminary training. He also sees his students launched into the world of practice, and meets them there afterwards, knows something of their requirements and difficulties, and has opportunities of observing defects in their methods or standards. He thus stands as an important intermediary observer between consecutive but at present too widely separated phases of education. An analysis of the curriculum as a whole and of existing teaching methods suggests to him that at every stage, both clinical and pre-clinical, there is too much instruction and too little education in its truer and better sense, and that the community of interest and purpose which should obtain between those responsible for the organization of earlier scientific and later clinical training is too rarely cultivated.

Medical education may be considered as falling into five periods. These are:

1. The school period prior to the year or years devoted to work for the First M.B.—a period which should surely, in the modern world, seek to prepare the way for a more scientific outlook in the population as a whole and to provide an early inspiration to those destined for the scientific professions, albeit without loss to general discipline.
2. The period devoted to work for the First M.B., whether this takes place at school or elsewhere (generally called the pre-medical period).
3. The pre-clinical period proper, which is spent at a medical school and concerns itself with the study of physiology, anatomy, and pharmacology, and, at some universities, of biochemistry and pathology.
4. The clinical period, which is spent at a teaching hospital.
5. The first postgraduate year, which is generally but by no means universally devoted to house appointments and should come to be regarded as an essential educational year in responsibility and practical experience.

Even though it be accepted that the main purpose of the education given in the second and third periods is to provide an introduction to scientific method and a proper familiarity with those sciences which are everywhere regarded as necessary to medicine, the work should ideally be organized throughout in such a way as to prepare the mind and interest of the student for the tasks which will engage his attention during the clinical years and, in fact, throughout the rest of his professional life. Without such provision there must be some loss of interest and organized thinking in the earlier stages, a lack of continuity between earlier and later training, and a groping for method at the beginning of the fourth or clinical period which the pre-clinical period should already have instilled.

At present certain of the shortcomings of the clinical period can unhesitatingly be referred to shortcomings in previous training. With a growing tendency to embark at too early an age upon specialized work for the First M.B., the general education of the student has assumed too low a level. Good literary standards, general knowledge, know-

ledge of languages, and interest in problems outside his own necessary sciences do not, with rare exceptions, characterize the equipment of the medical student. This is evident in his written work and examination papers, and often enough in his conversation, his reluctance or inability to share the literary, artistic, or socio-political enthusiasms of others in his generation, and often in his intellectual standards subsequent to qualification. However anxious he may be to make good these deficiencies, the overcrowding of the pre-clinical period proper hampers his endeavour in the early adult years. In comparison with the medical faculty at a university few faculties show a comparable multiplicity of subjects in their curricula or allow such scant leisure for private interests and recreation. The education of the mind and of the whole man inevitably suffers.

III. Some Present Defects in the Pre-clinical Years

Before proceeding to a consideration of remedies for these defects let us consider the First M.B. period and the university or pre-clinical period proper in a little more detail. In what respects does the teaching here fall short of what is to be desired? What are the particular mental faculties which it fails to encourage or to train?

Briefly, we may say that the whole of the teaching in the pre-medical and pre-clinical periods—allowing for exceptions in a few of the more advanced schools—is didactic and analytic. The student is taught facts and to memorize facts, and he is instructed in the analysis of certain natural or artificial phenomena, but at no stage as a rule is he given serious encouragement in the *observation of phenomena for himself*. Rather is the natural inquiring faculty of childhood unintentionally discouraged and inhibited year after year by too much teaching. Now the most essential faculty in clinical science and its application to practice is the ability to *observe naturally occurring phenomena*. Small wonder that the student entering the ward for the first time often feels or shows that he is entering a new world for which the world he leaves has inadequately prepared him. Here for the first time (unless of his own initiative he has indulged some naturalist hobby) he must learn to look and to see, to touch and to feel, to listen and to hear, and, furthermore, to interpret logically what he discovers with his senses and by the interrogation of his patient—types of inquiry for which the classroom and the laboratory have given him but a poor orientation. Clearly the didactic and analytic method cannot be dispensed with altogether, and chemistry, physics, biology, anatomy, physiology, and pharmacology are all essential studies. While, however, the teaching of the first two must remain in large part didactic, the teaching of biology, physiology, and anatomy might with reorganization encourage to a far greater extent than heretofore the faculties of observation and interpretation—the twin faculties so necessary to clinical science and practice.

At present, from the day when he first dissects the frog to that on which he concludes the dissection of the human cadaver, the student spends the greater part of his time in looking for things he is told to look for, in carrying out experiments prescribed by book or lecture, in remembering by means of diagram and table, in imagining physiological function in terms of tracings, graphs, and chemical formulae, in building his composite picture of the living human organism from inspections of the dead or of the decerebrate animal and from microscopical films or sections—in *constantly contemplating parts to the exclusion of wholes*. He is not customarily given a frog and told to observe all he can about it in the living state—its colouring and movements, its digestive or respiratory habits—without reference

at first to books or pictures, and to write down all he sees. Nor when it is pithed does he settle down, as Harvey would have had him do, to discover what he can of internal structure and related function.

After two years of lectures and laboratory work in physiology he may know much that has been discovered by others about carbohydrate metabolism, the acid-base equilibrium, the latest views on nerve conduction, the cardiographic tracing, the carotid sinus and Hering-Breuer reflexes, the theories of urinary secretion, the role of the accessory food factors—all valuable knowledge. About his own everyday movements and functions, however, and his own sensations and their responses to such things as exercise and changes of temperature and emotion, and about the temperamental and physical variability of those with whom he consorts, he may still be quite ill informed and unobservant. He lacks "an accurate acquaintance with the visible and tangible properties of things." If he notes peculiarities of feature or gait, of expression, habit, colouring, or body weight in others he does so casually and not critically, and without that curiosity and that urge to interpret in terms of intimate function or structure which are so essential a part of the mental behaviour of the good naturalist or clinician. Although he is supposed to have completed a study of the normal he knows little about growth in infancy or childhood, about the changes in such simple functions as the pulse and respiration rates between birth and adult life, or the other milestones of natural development. He has not watched healthy babies. Of such things, in fact, he often remains in ignorance until he starts his paediatric studies in his last clinical year. The occasions on which he has felt the radial pulse or apex beat critically and attentively or listened to the normal heart or examined the normal fundus and sought to describe his findings unaided have usually been very few. It is unlikely that he will have observed closely the subjective and objective phenomena of dyspnoea induced by effort in himself or his fellows, or have produced for contemplation and analysis varieties and degrees of pain in his own accessible structures. At present after a year or two in the wards he may remember something about the respiratory functions of the blood and yet be unable to describe or discuss and sometimes to recognize the manifestations and clinical varieties of disturbed respiration which are so valuable to diagnosis; visceral and other pains, for all their significant qualities, present themselves to him as phenomena of doubtful and difficult interpretation. The symptoms of health, and the transition from them through the symptoms of health modified by applied physical or psychological processes to the symptoms of developed disease, have rarely received consideration by him or his teachers.

And yet work along these lines would have been good physiology and would have supplied good training in scientific method, both of an observational and of an experimental kind. It would have had an obvious and immediate bearing on his ward work from its earliest days. It would have helped him by inculcating as a habit the exercise both of his sense organs and his wits, implementing the parallel discipline of a more repetitive and precise kind provided by the dissecting-room and the laboratory. The interest, bordering on excitement, of the first days of clinical work would then, too, be controlled and directed by past training; comparisons between normal, less normal, and frankly abnormal would be more readily and appreciatively made; disease and the symptoms of disease would have meaning from the beginning. Necessary instruction, in brief, would have been allied with and assisted by education in its truest sense, with interest more surely maintained and the goal of human medicine kept constantly in view.

IV. Some Remedies

To bring all this about it should not be necessary to lengthen the curriculum. Concentrating more on basic ideas and principles, much troublesome detail could be allowed to go by the board or be garnered slowly at a later date. The close co-operation of physiologists, anatomists, and clinical demonstrators would be needed, and eventually a new breed of teachers, uninfluenced by too specialized a concern for their own subjects, interested in each other's, and devoted rather to the discipline of inquiry at all stages than to the instillation of factual knowledge, would evolve.

Specific criticisms call for specific remedies.

1. In the school period biology (with elementary physiology in the final year) should become an obligatory cultural subject for every child from the age of 13 onwards, and should be taught alike to those adopting "classical" and "modern" programmes. There is no subject comparable with biology for stimulating lively and critical thinking or more important than biology as a proper introduction to the later understanding of man and his problems and of healthy citizenship. How slow we have been to implement the advice of Huxley and Spencer! At some schools the teaching of biology in this way has already been introduced with notably good effect. In combination with field work and the work of natural history societies the biological subjects not only provide a scope for observational training but also furnish teachers with opportunities of discovering just that type of boy or girl who is most likely to make a good student of the medical sciences and to find a vocation in medicine, and also of eliminating the unsuitable. In future a more careful selection of recruits for medicine will surely become necessary. Advice in respect of this selection should be among the more responsible duties of science masters, head masters, and the deans of medical schools. Having been studied from the beginning biology would present no difficulties as a First M.B. subject, and the special work for this examination could therefore be embarked on later. This work should not, in fact, be started until the school year in which the pupil reaches the age of 17. During this final school year the study of English literature and a language or mathematics should continue.

A higher standard and a more enlightened type of science teaching than obtains in many schools at the present day will be necessary, and it is to be hoped that some training for science masters in teaching method after obtaining their university degree will become obligatory.

2. The attempt to teach, and all within a period of two or three years, a very comprehensive topical anatomy with embryology (and sometimes comparative anatomy), physiology, pharmacology, biochemistry, and general pathology (with bacteriology) which obtains at present in some universities has necessitated a form of "cramming" which succeeds only partially in the training of organized and inquisitive minds. The first two university years should be devoted to the essentials only of topical anatomy and embryology with normal histology and to physiology with pharmacology. Human physiology and anatomy from the beginning should be developed along observational lines—whenever possible, and certainly more frequently than at present, employing the student himself as the object of study in conjunction with and illustration of other class-work on the several systems. After a pass examination in these subjects the final year should be devoted to honours work in human physiology (and applied biochemistry) as an essential subject and not more than one other subject, to be selected from a more advanced anatomy or general pathology or psychology dealing especially with the emotions and the special senses. In this year one or more weekly clinical classes introducing cases in or from the wards and a collaboration of clinical and pre-clinical teachers should be arranged in illustration of important physiological or pathological principles or processes.

The gaps in time and place between pre-clinical and clinical teaching must be bridged. There should be more frequent intercourse and discussion between the science masters in the schools, the university teachers of the pre-

clinical subjects, and the clinical teachers. For the last-named the whole-time opportunities enjoyed by the teachers of the earlier subjects must be provided on a more generous scale, so that education and its methods may become for more of them a primary concern. And finally, the teaching of science need not, as some scientists suppose, be harmed by frequent consideration of its practical and humane uses.

V. The Clinical Period

Thoughtfully introduced and wisely fostered, the discipline of the clinic is among the finest of all disciplines. It trains the senses; it teaches the value and uses of evidence; it exercises the logical faculty and requires the frequent balancing or correction of one method by another; it maintains the spirit of inquiry and compels humility; it demands the closest collaboration between science and humane feeling.

But clinical teaching in recent years, once of so high a repute in British hospitals, has suffered a certain disorganization and some loss both of method and of ideals. The conflict between the claims of practice and multiple public duties on the one hand and of teaching duties on the other (although there are great advantages in the combination of teaching and practice which must not be lost to view) has been partly to blame. The professorial units have not so far been potent to compensate or correct in any large degree.

The practice, for purposes of expedition, of instituting multiple investigations soon after the admission of a case to the ward has encouraged a faulty approach to problems and a neglect of historical evidence and the proper sequences of symptom-analysis. Investigation to the limit, often with no clear therapeutic policy to reward either the research or the patient, can cumber minds as well as beds. A small proportion of students in the clinical years are naturally observant from the first; some become observant in the course of time; many under stress of learning seem to lose the faculty they have begun to acquire; the majority trust too little to their senses and too much to the extraneous aids which they find ready to their hand. An x-ray-minded or laboratory-minded student, even if he writes a good report, may be unable to base his diagnosis on the evidence he has elicited although that evidence is sufficient for the purpose. He is for ever seeking other assistance and ignoring or missing what is set before him. His teachers do not always discourage this increasing over-reliance on accessory objective methods. He may be given some rules, but he is seldom given a system. He starts and continues his apprenticeship all too commonly with a haziness of mind that is accentuated by the looming menace of examinations. Clinical-clerking can provide a type of discipline in observation and reasoning of which we in this country have been justly proud. We must help it to come into its own again.

While the general plan of three-monthly appointments and of "firms" has stood the test of time, the following criticisms may be allowed as valid.

1. The proportionate allocation of time to the various clinical subjects is not rational. Too large a proportion is given to the special departments and too much time is spent in the operating theatre watching techniques which should not be intimately studied or practised until the postgraduate years. Too little time is spent in the medical wards, where alone the systematic examination of the case as a whole is insisted upon, and where the use of special instruments (ophthalmoscope, auriscope, laryngoscope, sigmoidoscope, sphygmomanometer) and the methods of the clinical laboratory can and should be intelligently taught and used in association with direct bedside method. An additional three months of medical clerking, with subtraction elsewhere, is much to be desired.

2. Medicine and surgery are at present separated from the beginning in a way which renders them almost rival subjects employing different methods—as though pathologies could be separated according to therapeutic procedure! The discipline and principles in medical and surgical wards are at variance. In the medical ward the student is expected to examine and write a report on the whole patient. In the surgical ward it is commonly considered enough if he examines the hernia or the lump and does not forget to examine the urine before the day of operation, and this notwithstanding that no patient more needs a general examination than one about to be subjected to anaesthesia and operation. Sometimes he sees cases for the first time in the theatre which have not been previously discussed and perhaps not even seen in the ward by the operating surgeon. Pre-operative and post-operative therapeutics considered at the bedside are of high educational value and should receive far more attention. It has taken a second world war to remind us all that Listerian and Hiltonian principles could still be more meticulously taught and practised. The principles of asepsis and measures to counteract cross-infection are or should be the same in medical and surgical wards. There may be nursing and administrative advantages in the separation of surgical from medical cases at the stage of operation, but at the stage of diagnosis there is no good reason for separating them. There are, in fact, strong arguments for combined medico-surgical units and for more frequent consultations before students between surgeon and physician on matters of diagnosis, on therapeutic decisions and alternatives, and on post-operative management and complications.

3. The sequence of appointments could be reconsidered with advantage. Although the usual order of junior surgical, junior medical, senior surgical, and senior medical dresserships and clerkships has much to commend it, and this order, as conducting from the simpler objective examinations to the more complicated study of all the systems, including the analysis of subjective phenomena, will still commend itself to most teachers, the alternative experiment of learning the general approach first with the full discipline of medical ward routine should be worthy of a trial. The special appointments which follow should be employed more for a continuance of the demonstration of general principles in diagnosis, prognosis, and treatment in medicine and surgery and less for the demonstration of specialized techniques. Neurology, orthopaedics, laryngology, and genito-urinary surgery can be made to provide the most valuable lessons in applied anatomy and physiology. In the matter of paediatrics we might well follow the practice of the Russian schools by giving it a much more prominent place in the curriculum. It is one of the most important subdivisions of general and preventive medicine. The handling of children and modifications of diagnostic approach necessary in their diseases are not at present sufficiently brought home to the undergraduate student. For the most part purely specialist teaching should, however, be postponed until the postgraduate period. The details, rarer problems, and operative techniques of ophthalmic, orthopaedic, and genito-urinary surgery and of throat and ear work are essentially postgraduate studies. Indeed, surgical technique as a whole should not claim much more of the student's time than radiological or bacteriological or chemical techniques. Principles and methods of study are the student's chief requirement, and above all constant practice in assembling evidence and in logical deduction from facts observed and symptoms elicited.

Psychological medicine must not be wholly concentrated in a department but should come to inspire the daily teaching of the medical and surgical wards. Regular clinico-pathological consultations on post-mortem material should be universally adopted. The chemist and the pathologist should be invited more often to ward discussions. The value of consultations as opposed to "second opinions" and interchanges of requests and reports must be impressed upon the student's mind from an early stage.

4. In the matter of lectures customs vary. Some schools have abandoned the systematic lecture in medicine and surgery in the belief that they are a duplication of textbook teaching. In replacing them, however, by a much greater number of clinical lectures by the many members of a staff too little trouble has been taken to secure enough lectures or lecture-demonstrations

on essential subjects and the commoner diseases. Some teachers lecture again and again on their own pet themes. Few go out of their way to discover what subjects have been covered in a recent session or what their colleagues are lecturing upon or what their students want. There is thus much overlapping and much omission. But what perhaps is needed most of all is a series of introductory lectures in each academic year by the professor of medicine or a senior physician on some of the main principles underlying the tasks of the applied science of medicine, of which all the special subjects are after all but subdivisions. Aetiology, the meaning of Diagnosis and the forms and uses of diagnostic method, Prognosis, and Therapeutic Principle are all surely worthy of separate discussion. There are few students who pause or are advised to consider how their approach to their work and to the individual case may be improved and amended by a better familiarity with basic ideas on such subjects and even by a better understanding of nomenclature. Lectures on main symptoms such as fever, pain, cough, and dyspnoea can also make an important contribution. Symptoms as expressing morbid physiology and signs as expressing morbid anatomy should, in fact, inspire frequent discussion. "What does this symptom mean?" not "What disease is it a symptom of?" should be the constant query in the mind.

5. The approach to the patient, the "management"—both in a physical and a psychological sense—as opposed to the more specific treatment of cases of the common diseases, with reminders that much sound treatment can be viewed as applied physiology, find frequent texts in the daily material of the clinic and yet are apt to suffer neglect in enthusiasm for the manifestations of a rare or "interesting" and often incurable case. On ward rounds the attempt to see too many patients in an afternoon is apt to lead to superficial or anecdotal teaching. Two or three cases carefully reviewed are less likely to leave bewilderment and a train of ill-digested ideas in the minds of the "firm." A part of out-patient teaching should be in the hands of senior members of the staff. Again a limited number of cases should be employed, but preferably not selected, for the purpose.

A proper perspective in the matter of accessory diagnostic methods, their place and limitations, and the interpretation of their findings is as necessary as insistence on the primary importance of the clinical survey.

6. It would be impossible in the space available to consider in detail the future of the teaching of obstetrics, of pathology and bacteriology in their special relation to medicine, and some important reforms needed in other special components of the curriculum. The belief is gaining general acceptance that a much broader "social medicine" course in illustration of the origins of ill-health and the social responsibilities of the doctor might come to replace the present dull teaching on "public health." It should occupy some part of the free period commonly devoted to fevers, anaesthetics, and vaccinations.

Postgraduate education, both in the house-officer period and later, and some overdue reforms in the examination system must also, for reasons of space, be omitted from present consideration.

VI. The Teachers

Finally, we must consider the clinical teachers themselves. It will surely by now be conceded that if anatomy, physiology, and pathology require whole-time teachers we can no longer accept that the much more difficult and essential subjects of Clinical Medicine, Surgery, and Obstetrics can be satisfactorily shared among a number of part-time teachers, each spending a few hours a week in the service of his school. On the whole-time professors of the three main subjects, in consultation with the dean of the school, should fall the duty of organizing the teaching on behalf of the students and the part-time staff and maintaining close educational contacts with the laboratory teachers. With the increase of specialism among physicians and surgeons, and their natural tendency to accumulate in their beds cases of particular interest to themselves, it becomes ever more important to have one or two large

units concerned with medicine as a whole and with beds open to cases of all types. The medical unit or combined medico-chirurgical unit should perform this function, and the professor, whatever special interests he may have, must remain a general physician (or surgeon) concerned with the principles and methods in accordance with which diagnoses and prognoses are achieved and with the lessons to be learned at the bedside, in the operating theatre, and in the post-mortem room from successes and from failures. At present it is not possible for all students in a given year to serve on the professorial units, where such exist. A combined medico-chirurgical unit and an additional three months for medical clerking should make it possible for all students to hold an appointment, whether medical or surgical, under the whole-time teachers and to obtain the advantages of work in the unit atmosphere. The clinical professor should whenever possible be a man with wide experience of institutional or consulting work, or both, and a developed interest in teaching. He should rarely be under 40 on assuming his chair. Such an appointment should not exclude the appointment also of a reader or associate professor in clinical science, whose main function would be research, who should accept limited teaching, and whose scientific activities should prove of the utmost value to the unit and provide frequent reminders for all its members that experiment as well as observation has an important part to play in education as in the advancement of learning generally. One general practitioner of high standing in the profession should also be attached to the unit and should engage in ward and out-patient consultations and give occasional classes on the management of a practice and of sickness in the home and the essentials of medical ethics. The opening of discussions on teaching among senior and junior members of the staff should be a regular function of the heads of units. Opportunities should be given to student representative bodies to register considered desires and criticisms.

In the medical school of the future we may perhaps visualize provisions (a) for whole-time clinical teaching staff, (b) for staff devoted entirely to institutional work, but sharing their time between and deriving their experience and income equally from a teaching school and a municipal hospital, and (c)—if private practice survives the war and the reconstruction—for staff giving half their time to their teaching school and the rest to private consulting work, albeit with facilities for most of this private work provided within the precincts of the hospital. With a healthy diversity of interests and experience thus secured; with closer contacts between the teachers themselves and between the staff, the students, and the house officers; and with a freer association within the hospital community of clinicians, chemists, and pathologists, and more consultations between them, we might picture the evolution of a clinical school and methods of training as far superior to what now obtains as are existing conditions to those which flourished in the days of the apprenticeship system and "walking the hospitals." Those days had certain things to commend them, and they witnessed the birth and infancy of our cherished bedside clinical teaching, but they allowed too free a rein to authoritarian instruction and lacked the inspiration, the checks, and the precisions of a preliminary and parallel education in scientific method.

Freedom to live and to learn must be secured first, but thereafter, with wise prevision and co-operation on the part of the State and the schools, and by dint of extracting the best from old experience and new experiment, who can doubt that we shall one day find the proper place and proportion for each science and service in the complex structure of our medical university or whole?

THE FUTURE OF MEDICAL EDUCATION A MEDICAL STUDENT'S VIEW

BY

DONALD McDONALD, B.A.

Radcliffe Infirmary, Oxford

To say that medicine and the medical profession need reforming is to-day to utter a commonplace. To decide how this shall be done is less easy. In the past the wider problems of medicine have been the hobby of more or less eminent members of the profession who are retired. To-day, sudden and violent change has become such a part of our daily life that everyone takes note, and the future has become the vital concern of everyone. As a sign of this, meetings of medical students from schools all over Britain, which were unknown ten years ago and embryonic four years ago, this year gathered almost 200 students at Cambridge, organized as the British Medical Students' Association. They discussed problems in every sphere of medicine; but, because the student of to-day is the doctor who will have to solve these problems to-morrow, and because the education he receives will make or mar his success in this task, medical education was held to be the most important link in the chain of medical planning.

The first and yet most vital problem is the actual entry into the medical school. For the individual who wants to be a doctor this is a question of money rather than ability. For the community, it determines very largely what sort of a doctor it will get; for, as one Spanish university has it, "What Nature has denied, Salamanca cannot supply." No one can doubt that the present methods of selecting medical students are haphazard in the extreme. A father's sentimentality; a desire for a safe job; almost any reason, except a desire to serve the community, is good enough, provided there is enough money for the initial heavy expenditure. Medical schools, bound up with the voluntary hospitals, have to accept such students as a source of income, using a very few scholarships as a means of advertising. The solution clearly must lie with the provision of a vastly increased number of scholarships by the State. Only then can students be chosen because they will make good doctors, which requires temperamental as well as intellectual qualities, and not for any other reason.

The Curriculum

The medical curriculum itself is long and arduous. This is inevitable because the subject is vast and the doctor needs to be efficient in every branch of it; therefore no one complains about its length. On the other hand, there is much that is useless and irrelevant which needs to be pruned away. The result of this will not be to shorten the whole course but to allow more important subjects to be introduced. The wartime need of getting doctors as quickly as possible introduces an important factor into immediate considerations of the question, but will not alter the long-term view of what is felt to be desirable. In chronological order, the pre-medical course in the elements of the physical and biological sciences comes first. It needs drastic revision, for it is poorly presented, uninformative, and a dead weight on the early enthusiasm of the student. Although its aims are entirely praiseworthy it is still planned, as in olden times, for the student who read only classics at school, and even possibly took a classical degree before proceeding to medicine. To-day that is true of very few, and certainly specialization at school should not be so advanced as to exclude anyone's reaching university standard from the elementary knowledge of physics and chemistry that is

required. In the meantime, the university teaching in these subjects could be much more imaginatively related to their application in medicine. On the other hand, students who have reached Higher Certificate standard in these subjects at school should not be forced to relearn them, as they are at many universities. With regard to biology the position is different. A sound understanding of the behaviour of living organisms in general is essential for the doctor, but the manner of presenting the subject is not the best. Botany is still based on the needs of the doctor who dealt directly with medicinal herbs. Zoology is planned on the Huxleian idea that evolution was in a single line and that a study of lower types will lead directly to an understanding of man. In practice this has led to the student's being required to know details of animals which are the failures, the dead-ends, of evolution. Man is the simplest mammalian type, and is easier to understand than other species which are highly specialized in one direction. Therefore the comparative anatomy learnt at this stage is actually much better introduced with human anatomy. A course in General Biology orientated to the special viewpoint of the doctor is required, and this should include the principles of heredity; the evolution of behaviour, which is necessary for an understanding of psychology; and also oecology—the study of animal communities—leading on to sociology. In recognition of the fundamental importance of this course it should be taught by the best and most mature teachers. A course of this type is given in America, and is found to be very successful. Some people go further and think that even more time should be given to broadening the outlook of the medical student. One suggestion is that at least a year between school and university should be spent in a job; this has a crude parallel in the military service required in Continental countries, and would hardly be acceptable to most students. Another plan would be to imitate the American method, in which a general university degree is taken before starting medicine; again the lengthening of the time as a student would be very irksome to most.

Technical Training

After completion of the introductory course the technical training of the doctor begins. Many criticisms are made of the way in which anatomy and physiology are taught, particularly as the mass of detail to be learnt is very burdensome; but, nevertheless, they are not always justified, for the future doctor and surgeon has to have the details of human anatomy at his finger-tips. The important question is to ask whether this essential knowledge is taught in the best way. The answer is definitely in the negative. In the first place, the two main subjects, anatomy and physiology, are taught as if they bore no relation whatsoever to each other, with the exception that, by a peculiar English custom, histology lives in the same building as physiology. The geographical separation of the dissecting-rooms has created an apparently insuperable obstacle in the relation of structure to function. A little co-operative discussion could surely solve this problem. Anatomy is traditionally learnt by mnemonics—which means without the co-operation of the intelligence. To some extent students are to blame for this, because there are many progressive anatomists who strive against this degradation of their subject. But the students, in turn, are ruled by the examinations and the unknown quantity of the external examiner, so that progress in an isolated school is very difficult. It has already been mentioned in this connexion that comparative anatomy illustrates and makes human anatomy more clear, and with this embryology should be included: both these subjects, which introduce a rationale into anatomy, are very much neglected in present teaching. This is not a plea for

pedanticism, but is of real practical importance; for anatomy learnt intelligently can never be completely forgotten as can that learnt by rote, when forgetting one letter of a mnemonic may mean making a complete farce of it facts.

The teaching of physiology is, on the whole, much better but once again suffers from a tendency to cram certain facts without understanding. In this subject the defect is more important, for, while anatomical detail remains the same for successive generations, physiology is advancing at tremendous rate. Therefore it is essential for the future doctor, if his medicine is to be based on sound physiology to learn it in a scientific flexible way with an understanding of past developments that will enable him to keep track of its advances in the future. In the past only Oxford and Cambridge have specifically set out to do this, and the allocated a whole year to take an honours course in animal physiology. It was popular in spite of the extra year required, which means that its value was appreciated by students as well as teachers. Unfortunately, in the interests of the war, this course has been omitted; but in the future its example should be taken heed of, if not in the formal sense of a year's course, at least in the way that physiology is taught. In addition to the intellectual approach, the course provided excellent technical practice, of which the best was in mammalian physiology, for this is the only chance students get of handling living material before they have to deal with patients on the operating table.

The teaching of structure and function together is an obvious need. Equally essential is the comparison of the diseased with the normal. While it is necessary to appreciate that the student cannot do every subject at once, yet it must be remembered that the pre-clinical subjects are taught for use in clinical medicine, so that the introduction of clinical material early in the course illustrates and gives direction to the learning of anatomy and physiology. Study of the nervous system is the outstanding example in which function and anatomy need to be taught together and then directly applied to the neurological case. Instead of this, each part is taught quite independently, in different places, at different periods, with a great amount of repetition which is wearisome and a waste of time.

Clinical Teaching

In clinical teaching the most frequent criticisms are directed against rather different objects. This is because the whole environment changes from an academic to a professional one. The student is told that the objects of his studies are, first, diagnosis; second, diagnosis; and third, again diagnosis! But the student, while never denying its importance, wonders if this is quite enough. Has he really done all that he can if he listens to a tuberculous lung for six months and then, having diagnosed a healing condition, sends the patient back to the slums he came from? Is it really sufficient to study ten cases of children with rheumatic heart disease without observing that they all come from a district with notoriously bad damp housing? No, it is not enough; and the fact that students in conference bring such criticism up again and again shows that they feel frustrated by the present scope of their teaching. The teaching of Preventive Medicine is a widespread and urgent demand which is neglected almost everywhere. Public health lectures, as given at present, deal with the legal aspects of sanitation, and no more.

The great majority of students are going to be general practitioners, forming the vanguard of any advance to improved health for the community the profession is going to make. On them will rest the responsibility of diagnosing disease early. Yet the material they are taught with is so

almost entirely "interesting" cases of rare diseases or with advanced physical signs. This has some justification, for the specialist naturally collects cases in his own specialty, and the loudest murmur is the one for the beginner to listen to. On the other hand, the senior student who has learnt to recognize physical signs can apply his knowledge in clinics, which is the nearest thing to general practice that hospitals provide. Out-patient clinics are fairly good for this purpose if they are not overcrowded, but municipal clinics that some London students go to are better, and the dispensary system in Scotland probably best of all. Another major problem in general practice is the maladjusted, possibly mildly neurotic, patient. A field in which a great deal of good can be done, it is almost entirely neglected by present-day medical education. Psychology consists of a few lectures in the major psychoses, illustrated by the most amusing inmates that the mental hospital can produce. This is a most important omission that can and should be rectified. Also in general practice in industrial centres diseases due to working conditions and industrial processes are constantly being met, yet training in recognizing them is confined to possibly two lectures in a public health course. In all these ways could medical education be more closely related to the needs of the doctor after qualifying.

The manner in which teaching is carried out falls short of the ideal. Units tend to be much too large for the best results, as, particularly in the wards, the information does not reach many of the listeners, and there is no opportunity at all of asking questions or taking part in discussion. Lectures are often compulsory, in which case the student is denied even the simple criticism of stopping away, and the lectures may become slovenly as a result. Reading from textbooks has been redundant since the invention of printing. During the last two years, when many schools have been evacuated, it has been found that the formation of seminar groups between teacher and students, with free discussion, has led to the most successful results. At the same time the ability to criticize lecturers has resulted in marked improvements. Thus the formation of staff-student groups to discuss the organizational problems in a school is found to be effective from all points of view, revolutionary though it may seem. The other alternative suggestion is that the staff of a medical school should have had a pedagogical training, or at least be chosen for teaching ability rather than for research. Many feel, however, that this would kill any scientific life in the teaching through replacing scientists by orators, for if the research worker is good he will have such a clear idea of his subject that he cannot talk badly about it. The way forward shown by helpful mutual criticism between teachers and taught seems to be by far the most promising.

The provision of smaller teaching units also enables students to get far more practical experience of the various techniques, such as lumbar puncture, intravenous infusions, and so on, that he will need to be able to do as a doctor. Opportunity for this varies greatly in various medical schools, and it cannot be doubted that the complete divorce of the student from practical work is very bad. On the other hand, there is often required a tremendous amount of attendance at operations which in fact can demonstrate nothing to those more than a yard from the operative site. Perhaps most important of all is training in casualty work, for minor surgery plays a large part in a practising doctor's life. The aerial warfare of to-day makes it doubly important: in fact, the teaching of this subject has been greatly extended since the beginning of the war, but there is doubtless still room for improvement in some places.

Conclusion

A great many of the points mentioned can be easily changed by local adjustment, and usually the staff are very willing to accept suggestions for improvement. Broadly, however, the aims of medical teaching can only be altered, so that they fulfil the needs of the doctor and enable him to serve the community to the best of his ability, on a national scale. The British Medical Students' Association is going to present, by invitation, a memorandum to the Planning Commission set up by the B.M.A., and by this means it is hoped that the necessary changes will be effected.

CLINICAL OBSERVATIONS ON AIR-RAID CASUALTIES*

BY

R. T. GRANT, M.D., F.R.S.

AND

E. B. REEVE, B.M., M.R.C.P.

The Clinical Research Unit, Guy's Hospital

Comments on Treatment: (a) Transfusion

It is apparent that the great majority of the cases in all groups respond well to treatment, at least for a time. The simple measures of rest, warmth, morphine administration, and the head-down position, however, are usually insufficient to effect lasting improvement. We have seen that only 17 cases escaped transfusion; none of these is regarded as having suffered severe blood loss, the haemorrhage being assessed as little or none in 13, moderate in 2, and as unknown in 2. In the majority, also, the injuries are classified as minor or moderate (4 and 7 respectively), in only 4 as severe, and in 2 as internal. In several of them transfusion probably ought to have been given, and would have hastened improvement.

The other 83 cases received transfusions in amounts and at rates that differed greatly. Blood and plasma together were given in 50 instances, blood alone in 13, and plasma in 15; sometimes serum was used instead of plasma, and in a few various salines were added. The amounts, including those given before, during, and in some cases after operation, vary from one pint to thirteen pints (this last amount being administered over a period of twenty-eight hours); 23 received two pints or less, 29 from two to four, 18 from four to six, and 13 more than six pints. In general these amounts are related to the blood loss rather than to the nature of the injury, the larger transfusions being given mainly where bleeding was renewed either before or at operation. The amount required for resuscitation varies so greatly from patient to patient that no definite ruling on this point can be given. While the end in view seems to have been the replacement of lost blood, the restoration and maintenance of normal systolic blood pressure (100 mm. Hg and over) is used as the chief indication that an adequate amount has been received.

In most cases the early transfusions were given at a rate of about one pint in a quarter or half an hour: later transfusions, unless to combat renewed bleeding, were administered more slowly—one pint over one or more hours. More rapid transfusions have been given, apparently without other than good effect: in one instance two pints was administered in fourteen minutes with general

* Concluded from p. 297.

improvement and a rise of blood pressure from 40/20 to 130/70 mm. Hg. The rise of pressure, however, accompanying a rapid transfusion is not always maintained; for example, in one case the blood pressure rose from 70/38 to 134/50 when two pints of plasma was given in twenty-five minutes, but soon fell away again to below 100 mm. Further, rapid transfusion is not always well tolerated; in one case restlessness developed during the transfusion of one pint of plasma in five minutes and one pint of blood in eight minutes; in two others restlessness and increased rate and depth of respiration were noted to come and go with the speeding and slowing of the transfusion. On the other hand a slow transfusion may be ineffective, the blood pressure remaining low or continuing to fall until the rate is increased. Thus in one case (fractures of skull and legs; severe blood loss but no continuing bleeding) 1,400 c.cm. of plasma was given over a period of eleven hours. At the start (one and a quarter hours after injury) the patient was pale, sweating, restless, and excited, and was vomiting; the blood pressure was 100/65 and the pulse rate 125. During the transfusion period the patient became worse, and was semi-comatose, with sighing respirations; pallor persisted, the blood pressure fell gradually to 70/40, and the pulse rate rose to over 140. The rate of transfusion was then quickened (how much is not stated), and after half an hour the blood pressure had reached 110/68; improvement continued, and after another half-hour (during part of which time oxygen was also given) the blood pressure was 120/80, the facial colour good, and the patient fully conscious. Another patient (leg severed through thigh; much laceration), who had lost much blood before and at least a pint during operation, became very ill towards the end of it. Although a blood drip was running slowly, his respirations became rapid (25 a minute) and shallow; and his radial and carotid pulses failed, being palpable only for short spells, and then grossly irregular. After the end of the operation his face and extremities suddenly became pale and he sweated profusely; he lay motionless and apparently unresponsive, though round from the anaesthetic (pentothal, gas-oxygen-ether). The bottle of blood was nearly empty and no more was available; plasma was not obtained until a quarter of an hour. During this time oxygen was given by B.L.B. mask without improvement. The plasma was then transfused at the rate of one pint in twenty minutes. The observer remarks that he expected the patient to die, but that in fifteen minutes there was a remarkable change: the pulse was regular and of good volume, its rate 120 a minute; the blood pressure was 135/70 and the respirations 15; his mental condition had improved greatly, and he conversed normally.

In most cases improvement is pronounced within a few hours of beginning transfusion, being shown by a lessening of pallor (sometimes restoration of a good colour) the cessation of sweating, a feeling of warmth, and a rise of blood pressure to over 100 mm.; slow pulses tend to increase and rapid ones to fall towards normal rates. In some the improvement is dramatic in its rapidity. In a few the response is slow: thus in one instance transfusion of two pints of plasma in the early stages raised the systolic blood pressure from 50 to 90 mm. but no further, though recovery took place later. This case also illustrates that one factor slowing improvement is delay in beginning transfusion. The patient was not admitted to hospital until five and a half hours after injury; transfusion was begun seven and a quarter hours after injury. Blood pressure was not established at normal levels until some time after operation—about thirty-nine hours after injury.

As a general rule, in the absence of continued bleeding, if no material improvement takes place after giving two or

three pints of blood or plasma at an adequate rate, later improvement is unlikely. Only 6 patients showed no improvement after amounts varying from two to six pints, and all soon died; in 3 failure to respond was associated with uncontrollable bleeding; this factor was not evident in the others.

(b) Reaction to Transfusion

A reaction to transfusion is recorded in 15 cases (18%). Rigors are noted in 14, but in one case pallor, a feeling of coldness, and a temporary rise of blood pressure occurred without rigors. We believe from our own experience that reactions are even more frequent than is shown. Unless the patient is carefully watched reactions may be easily overlooked when shivering is slight or absent and the only signs are increased pallor, coldness, a diminution in the pulse volume, and a temporary rise of blood pressure.

(c) Operative Treatment and Anaesthesia

Eighty-three cases underwent operation; the time after admission at which operation was begun and the duration of operation are noted in 68. Operation was begun within two hours in 18 cases, four hours in 23, six in 5, twelve in 20, and twenty-four hours in the remaining 11. In the majority operation lasted an hour or less (49 cases), between one and two hours in 15, and between two and three hours in 4. Too many factors seem to have influenced these times to allow analysis to bring out clearly what we have gathered from our own experience—namely, that the sooner operation is begun, after resuscitation in those cases requiring it, and the more rapidly it is carried out, the better for the patient. The danger of delay is illustrated by two comparable cases. Both patients were young and healthy men with badly smashed legs, and were severely ill on admission. They were soon revived by transfusions; in both, double amputation was rapidly carried out by two surgeons operating together, transfusion being continued. In one case operation was begun within two hours of admission, and the patient survived. In the other operation was delayed for seventeen hours; the patient became gravely ill during operation, responded poorly to further transfusion, and died about eight hours later.

It has been seen that a considerable proportion of cases deteriorate at operation. The data given are too meagre for an analysis of the factors involved, but in at least 9 cases renewed bleeding was the chief. These findings serve to emphasize three practical points. The first is the necessity for carefully watching the patient during operation for signs of deterioration: the best indicator is the state of the blood pressure. The second is the importance of keeping blood loss at operation minimal; and the third, the need for continuing transfusion at drip rate during operation so that at any time it can be speeded up to compensate for further haemorrhage.

Data on the induction and course of anaesthesia are scanty, and in 23 of the 83 cases no note is given of the anaesthetic used. The gas-oxygen-ether anaesthetic was used in 45, ether in 4, pentothal or evipan in 4, a local anaesthetic in 5, and a spinal in 2. We are of the opinion that too little attention is paid to this aspect of treatment, and from our own experience we urge that the anaesthetic should be administered by a skilled anaesthetist. The series affords no material for comparing the efficacy of different anaesthetics: from what we have seen the gas-oxygen-ether mixture well administered is a safe and satisfactory anaesthetic. It is of interest to note that in two cases a spinal anaesthetic was given before operation for "shock"; in both of them the blood pressure fell further and was later restored by transfusion.

Phasic Variations in Blood Pressure : Cardiac Irregularities

In passing, attention is drawn to a commonly occurring phasic variation in blood pressure, corresponding to the "pulsus paradoxus." The pressure rises with expiration and falls with inspiration. The amplitude is often no more than 5 to 10 mm.; but it may greatly exceed this, and in one case reached 50 mm. It often becomes apparent during anaesthesia, but occurs apart from this. It does not seem to be associated with any particular injury or with obstructed respiration. Its significance is not understood, and further observations are required.

Cardiac irregularities also are not infrequent. Extrasystoles are the commonest, but auricular fibrillation and pulsus alternans have been met with. These irregularities usually pass off as the patient's condition improves.

Disturbance of Renal Function

A feature of interest is a commonly occurring disturbance of renal function; its frequency is unknown, for observations have been insufficient. The chief characteristics are a delay in passing urine (up to thirty-six hours) and the presence of abnormal constituents in the urine for a day or two (albumin and red blood cells, less often casts, and occasionally sugar). The delay in passing urine is in most cases not due to retention, for the bladder does not fill, and in some patients who have died without passing urine little has been found in the bladder at necropsy. The delay may be followed by several days of reduced urinary output in spite of plentiful fluid intake, which may be succeeded by a period of increased diuresis. In some instances the blood urea is raised. While in most cases the disturbance is relatively slight and transient, in a few it is more severe and longer-lasting, and in two cases death appears to have been due to renal failure. In neither was the renal failure adequately explained at necropsy, though in one case fat emboli were discovered in the kidneys. Examples of the disturbance are given in the case histories quoted under Groups I and IIIA (pp. 294 and 296). Whether all these cases fall into one category or whether or not the renal disturbance is the same as that occurring in the "crush syndrome" remains unknown. So far as evidence goes the disturbance is not clearly related to age, blood pressure, severity of wounds or haemorrhage, or transfusion. Further observations are necessary.

Deaths

Although most of the cases responded so well to treatment, yet in a high proportion improvement was only temporary. The table (p. 293) shows that of the 100 patients 44 are known to have died: none in Group I; 7 (or one-quarter) of Group II; 4 (or just under one-half) in Group IIIA; and 15 and 18 (or more than a half) in Groups IIIB and IIIC respectively. This probably does not fully represent the mortality of the series, for, as the table also shows, the after-history is no more than twenty-four hours for 10 cases, forty-eight hours for 6, and seventy-two hours for 2. None of the 5 patients with minor injuries died, and only 1 of the 17 with injuries classified as moderately severe. Of the 41 with severe injuries 14 (34%) died, and no fewer than 28 (76%) of the 37 with internal injuries. The majority (27) of the deaths occurred within twenty-four hours of admission to hospital. 11 within forty-eight, 3 within seventy-two, 1 on the fourth day (renal failure), the other 2 on the eighth day (one from renal failure and one from gas gangrene). Fourteen died without reaching operation, 6 died on the table, and 23 died after operation.

In 21 instances death can be accounted for more or less satisfactorily by the nature of the internal injuries; in 8 cases details are insufficient from this point of view. Gas gangrene accounts for two deaths, renal failure also for two; one is attributed to too deep anaesthesia. Insufficient transfusion is probably responsible for one, only one pint of plasma having been given though severe haemorrhage was likely. In another, death occurred when operation had lasted two hours, and in this case also transfusion was begun late.

In the remaining 8 cases death is not readily accounted for. They are alike in that all had improved greatly with transfusion and all except one underwent operation and remained for a time in a more or less satisfactory condition. Then unexpectedly these patients deteriorated progressively and died. The recorded details of the later course are too meagre for further comment in three cases, but in the others the description suggests a pulmonary or cerebral complication. In one, restlessness, delirium, rising pulse and respiration rates, a profound fall of blood pressure, cyanosis, and convulsive attacks are described; in two others the symptoms were similar though convulsions were lacking. A third displayed intense headache, extensor plantar reflexes, and coma. Plasma transfusion did not improve the state of two, nor did venesection a third; oxygen was tried without avail in several. In none was a satisfactory explanation for death found at necropsy. Fat emboli were looked for in six cases, and were found in the lungs, brain, and kidneys in two and in the lungs only in three; they were not very numerous, and it is doubtful if death can be rightly attributed to this cause. No common feature in their injuries or treatment suggests an explanation. More observations are required. It is probable that such cases are more frequent than the series suggests: the final stages are apt to be missed, since they occur at a time when the interest in resuscitation has passed.

Concluding Remarks

The majority of these cases were regarded on admission to hospital as instances of shock. If this is accepted, then it is clear that "shock" is no readily recognizable clinical entity. The survey of the cases, we think, bears out our impression that the grounds for the diagnosis of "shock" depend rather on the personal views of the individual making it than on definite and well-established criteria. In our experience the term is so loosely used in practice as not to give an indication of what we should expect to see at the bedside; it does not tell us how ill the patient is, what symptoms and signs he displays, or what treatment he requires. We prefer not to apply this label to these cases. We have shown that there is much to be learnt of the reaction or reactions to injury, and believe it is only by continued observation and analysis that we can learn more. Haemorrhage plays an important part, but is not the sole factor involved. Many more accurate and detailed case records are needed: attention is drawn to the "Memorandum on the Observations required in Cases of Wound Shock," which appears in this issue at page 332.

These observations have taught us much about treatment. Many of these patients are severely injured and have lost much blood; left untreated, they soon become dangerously ill, if they are not so already. The simple measures of rest, warmth, and morphine administration are usually insufficient for their recovery, but a transfusion of blood or plasma properly given is a most potent means of restoring or maintaining the circulation.

In assessing the need for transfusion emphasis is placed on the severity of the injury and blood loss rather than on

blood pressure; nevertheless, the course of the blood pressure is the best available indicator of response to treatment, and its determination should not be omitted. In severely wounded cases with evidence of blood loss, transfusion should be begun without delay, whatever the blood pressure. Early transfusion should be given at the rate of about one pint in fifteen minutes or half an hour; later transfusions, unless to combat renewed bleeding, more slowly—one pint over one or more hours. More rapid rates may not be well tolerated; slower ones may prove ineffective.

The restoration and maintenance of blood pressure to about or above 100 mm. is a good indication that an adequate amount has been transfused. The response to transfusion may be dramatic in its rapidity; usually it is more gradual. Few cases fail to respond: in the absence of continued bleeding, lack of improvement after the giving of two to three pints of plasma or blood indicates small chance of recovery.

Operation should be carried out as soon as possible after the patient is revived. At operation as little as possible should be done as quickly as possible, and blood loss must be kept minimal. The gas-oxygen-ether mixture is a safe and satisfactory anaesthetic; its administration should be in skilled hands. Transfusion ought to be continued during operation and the patient carefully watched for signs of collapse.

In the post-operative period the patient still requires to be carefully watched for several hours; transfusion is often necessary. Even in patients well restored and safely past operation, death may occur unexpectedly within forty-eight hours.

In many cases, owing to the nature of their wounds, improvement is but temporary and is followed by deterioration and death. Nevertheless, because of the difficulty in foretelling the outcome, transfusion should not be withheld, no matter how dangerously wounded the patient appears to be when he comes under observation.

MEMORANDUM ON THE OBSERVATIONS REQUIRED IN CASES OF WOUND SHOCK

BY

R. T. GRANT, M.D., F.R.S.

The Clinical Research Unit, Guy's Hospital

The following memorandum was prepared for the Medical Research Council's Committee on Traumatic Shock and issued in February, 1941, to a number of medical officers in the London area. The memorandum has proved useful, and is now published in the hope that medical officers elsewhere may also help in collecting the required information. Case records should be sent to the Secretary, the Committee on Traumatic Shock, Medical Research Council, c/o the London School of Hygiene, Keppel Street, London, W.C.1. A brief account of the observations made so far also appears in this and the previous issue (pp. 293 and 329).

Close observation of air-raid casualties shows that in spite of all the work already done, especially in the last war, little is known of the nature and treatment of traumatic or wound shock. In the first place there is in practice a wide variation in the application of the diagnosis of "shock." Some medical officers apply the label "shocked" to any patient, however slightly wounded, who seems ill, is perhaps pale, and has a weak pulse. Others

restrict it to cases displaying low blood pressure, a rapid thready pulse, pallor or cyanosis, a cold and sweating skin, shallow and rapid respiration, and often vomiting, restlessness, a lessened sensibility, and a dulled mental state. To the majority the criteria of "shock" are severe injury and low blood pressure. It follows that those who apply the diagnosis in the first sense see many more cases and obtain better results in the treatment of "shock" than those who apply it with more restraint.

Secondly, the clinical manifestations presented by injured patients are varied: some cases of so-called "shock" recover quickly with only rest and warmth, some require transfusion, and others die whatever treatment is given. It seems likely that there are different types of "shock," but we have not yet learnt to distinguish them clearly at the bedside. Prognosis is often at fault and treatment in doubt. Moreover, the lack of a common basis of diagnosis makes it impossible to assess the efficacy of the various methods of treatment adopted.

For these reasons it is better to avoid the diagnosis of "shock" and to replace it by an accurate and complete record of a patient's state and progress, together with the treatment given. It is only by accumulating and analysing such records that we can hope to learn if the patients do fall into different clinical groups, with differing prognoses and requiring different treatments. It is only thus we may pave the way for further observation and experiment directed towards understanding the mechanism of "shock" in its various forms.

The same need for careful observations on "shocked" and wounded soldiers was realized in the last war, and much was accomplished by special observers in France in spite of difficulties associated with active service abroad. Much remains to be done, and the opportunities for observation are more favourable now than then. Valuable material is passing through our hospitals either unrecorded or insufficiently documented. It is important that case-records should be made on a uniform plan, and the following notes have been compiled for the guidance of medical officers who have the opportunity of dealing with air-raid casualties and who are willing to undertake such work. On page 333 is an example of the type of detailed case record desired.

This work is exacting; it often requires that an observer should remain by one patient almost continuously for hours. It follows that only one or at most two cases can be satisfactorily dealt with on any single occasion unless the medical officer has available helpers on whose observations he can rely. A few records fully documented are of far greater value than scrappy notes on many cases. Observations need not be confined to air-raid casualties: they are equally valuable when applied to accident cases or surgical emergencies.

NOTES ON OBSERVATIONS

A complete record should be kept of all that happens to a patient from the time he comes under observation until he is out of danger or dies. It is most important that all observations should be recorded at the time they are made and that the times of the observations should be noted. These points are often overlooked by unpractised observers, and require emphasis.

An attempt should be made also to find out what happened to the patient before he came under observation. The circumstances of the injury should be inquired into: when the patient was injured; what he was doing at the time; how near the bomb fell; whether he was buried or left exposed; whether or not blood was lost, and how

Date and Time of Admission: 8.11.40, 7 p.m.

Age: 33 years

Sex: Male.

Time of Injury: 6.30 p.m.

MEDICAL RESEARCH COUNCIL

Time	Pulse	B.P.	Resp.	Observations	Time	Pulse	B.P.	Resp.	Observations
7.50	?	70/7		I.M.H. gr. 1/4. 3 ccm. A.T.S. B.L.B. mask on. Said to be ashen pale and sweating profusely. Pulse, impalpable, rapid breathing, cold extremities.	9.11.40 a.m.				Suddenly forehead and extremities pale and sweating. Doctors present take a grave view. Carotid pulses barely palpable and only in bursts at wrist. With some delay another vein needed. Coming round from anaesthesia.
8.00	?	60-70/7		Plasma, Group O, 1 pint started.	12.30 (cont.)				Transferred to bed in theatre; foot of bed raised; bed moved to resuscitation room next door to theatre. Hot cradle on. B.L.B. mask on. Very ill. Only about 50 ccm. of blood left in transfusion bottle. Plasma is being filtered, but very slowly. Transfusion rate a slow drip to make blood last; but if drip speeded up he immediately improves, only to fall away again when it is slowed.
8.30	140		28	Skin colour fair. Warm. Pinhead pupils. Mental state clear. B.L.B. mask in place—tolerated well.					257 Breathing very shallow. Pulse as above. B.P. unrecordable. Fair colour in skin of forehead and lips. Sweating on forehead. Exposed extremities cold.
8.45	128	70/50	18	Injuries: Leg off at level of lower right thigh. Severely lacerated. Has been cleaned up and packed. No sweating. Exposed hand rather cool. Apparently no other injury.	12.45	?			Breathing very shallow. Extremely ill. Citrate and plasma at last; run in pretty rapidly, about 1 pint in 20 mins. Pulses still as before. Lies quiet; does not talk; appears semi-conscious. I went away thinking he would die.
8.50				Pulse (ft. radial) regular, then volume. No pause after expiration; respiration regular. Skin colour of face still quite good. Hand not particularly cold, but slightly bluish.					Miraculous change. Pulse good volume. Mental state clear and normal. Feels better. This pint of plasma finished.
9.00	120	78/56	17	Has had 1 pint of plasma. Blood, 1 pint, started. Patient sleeping. Rt. arm bandaged from elbow to wrist to keep warm. Rt. hand exposed.	1.00	120	135/70		Blood, 1 pint, started. Pulse regular and no fluctuation. Mentally quite normal now. Thirsty. Lips moistened with water. Sips of water.
9.15	122	84/56	17	Respiratory variation of B.P. Hand cold. Slight sighing resps. Blood running at about 3 drops a second. Skin of face paler but not bloodless. Lips appear to be slightly quivered. Lying quite quiet. Patient feels not too bad. Has had hot cradle over lower part of body and legs since 8.45 p.m. Rt. hand exposed.	1.10				Pulse good volume and regular, with occasional poor beats. Forehead moist. Ears and nose warm.
9.30	120	92/58	16	Rt. hand cold. Forehead and cheeks cool. Colour of face definitely paler. Blood taken from rt. thumb. Squeezing and congestion to get blood drop. Hb 80-82% (Gowers's method). Patient quiet and drowsy.	1.15	128	120/70	15	Warm, quite comfortable, not too hot. Skin colour good. Entirely rational. Feeling well to himself. Resps. deep and even. Pulse regular and even. Remarkable recovery.
9.45	124	100/60	16	No respiratory variation of B.P. now. Lips pinker. Ears cool to warm. Sull quiet. Foot of bed raised. Ears and lips colour better. Mental state clear. Patient says his back is burning.	1.30	128	125/70		Norm in good condition. Hb from blood at 1.45 a.m.—88% (Gowers's method). Blood: about 250 ccm. of this last 550 ccm. has now gone in.
9.55	122	118/79	15	Hand not so cool, but coolish—more blood in it. Veins visible. Tummy—no sign of milk.	1.55	128	120/80	14	Pulse good volume and regular, with occasional poor beats. Forehead moist. Ears and nose warm.
10.00	122			Exposed hand cool but warmer. Skin of face, ears, and lips good colour. Patient quiet and co-operative. Free flow of oxygen into B.L.B. mask.					Temp. 97.6° F.
10.15	124	140/70	14	Exposed hand good colour though still cool. Colour of cheeks, lips, and ears still good. Pulse thin. Vasoconstriction.	12.30	120	140/35		Temp. 100.2° F.
10.20				Has now had 1 pint of blood. Second pint of blood started. O ₂ still bubbling through mask. Stump has bled a little but not much. Patient asked for pillow under rt. leg. Still quiet and cool.					General condition good. For last 2 days pulse average 96-106. Temp. swinging 98°-100.6° F. Mental condition fine. Having sulphapyridine, which gives him a headache and makes him feel sick. B.P. 150/88 three times. ? excitement. Skin hot. Lips and skin a little pale. Pulse good volume. Hb taken 84%.
10.30	128	136/70	16	Exposed hand warming. Colour of exposed hand good; also cheeks, ears, and lips a good colour. B.P. shows respiratory variation.					Pulse good volume, regular. Mentally normal. Since Monday, 11/11/40: Average temp. = 98.5°-100° F. swinging. = pulse = 93-104. = resp. = 20.
10.35				Hb (rt. thumb) 95% (Gowers's method. Hb (squeezing and squeezing —) was done after he had had 1 pint of plasma, 1 pint of stored blood and 100 ccm. of new bottle of blood. O ₂ now off.	10.11/40 a.m.	6.00		20	Sulphapyridine stopped 12/11/40. Had 2 pints of blood, Group O, on 13/11/40. On 15/11/40 Hb was 90%.
10.40				Slight rhythmic fluctuation of B.P. Respiration regular and even so far.	10.00	96		20	Evening. Fast sudden onset of pain in chest. Got worse and limited inspiration. Doctor thought he could detect signs of pleurisy. No cough. No sputum; 1.5.4.1. haemorrhysis.
10.45	144	134/68	17	Vomited 1 oz. Face a bit congested. Forehead sweating. Lips not so pink. Quite rational. Says he was in house about 6.30 p.m. Bomb dropped and house fell on him. Also coal-gas escape.	11.11/40 p.m.	3.30		150/88	Temp. persisted about 100°-101° F. Pulse went up from 100 av. to 110-120. Given sulphapyridine and sulphathiazole in large doses.
10.50				I think a bit bluer since O ₂ off. Hb on last few drops of last bottle of blood done—106% approximately. ? a fair sample. Quite clear-headed.					Seen at 3 p.m. Feels better, but now on sulphathiazole instead of sulphapyridine. Still some pain. Still no cough or sputum. I should think probably an infarct.
11.00	132	136/70	14	Slightly more fluctuation in B.P.	15.11/40 p.m.	3.00	100	140/80	One small haemoptoe. No cough. No sputum. Pulse 116-120. Temp. 101°-102° F.
11.15	128	130/90		Feels good in himself. Pupils still pinhead. Hands warmish, good colour. Blood in skin veins. Comfortably warm. Calm. Probably fit for operation.					Temp. 99°-100.4° F. Pulse av. 100.
11.25	128	134/85	16	Hb 96-100%.					Recommendation of pleuritic pain in his opposite side (rt.). Mild attack. Respiration good. Pulse normal. General condition good. Radiograph ? small opacity just above left diaphragm.
11.45				Anaesthetic started. Pentothal intravenously. ? how much, followed by gas-oxygen and ether; 80% O ₂ and not much ether or N ₂ O necessary to dope him. Moved into theatre. Blood drip not now running very well. Moved on to table.	16.11/40				
				Stump wound (about through knee) cleaned up and isolated in sterile towel. Amputation through about middle of femur. Well and rapidly done. Total operation time about 30 mins. Tourniquet above operation field. On about 20 mins. A fair amount of blood loss. I should say at least 1½ pints, but this may be an over-estimate.	18.11/40				
9.11/40 a.m.	?	?		Operation finished. Stump sewn up. Operated on with head lowered and legs raised, and blood drip running in badly, partially subcutaneously.	19.11/40				
12.30				Now flat out. Rapid breathing (and shallow). Pulse at wrist impalpable except in bursts, when gross irregularity of rate and rhythm can be detected. Has been like this for the last 15 mins.	21.11/40				
					22.11/40				
					22.11/40				

Note.—To bring the readings of the Gowers haemoglobinometer used to a "normal" standard in which the blood of average healthy men is represented as containing 100% haemoglobin, correct the readings here recorded by subtracting from them $R \times 30$, where R is the given reading.

much; what treatment he was given. The amount and time of administration of morphine or other drug should be noted, as also the time of application of a tourniquet. It may be impossible to get this information from the patient, but it can often be obtained sooner or later from other witnesses. The injuries observed on admission and later, including radiographic and operation findings, should be fully described.

The general condition of the patient should be noted. State, for example, if he is mentally clear, apathetic, drowsy, comatose, talkative, delirious; what his memory is for events up to and since the time of injury (concussion); whether he is frightened or calm; if he is in pain; whether the eyes are sunken and closed, or staring; what is the state of the pupils. Some patients are deafened by the explosion; even in the absence of deafness it is advisable to examine the ear drums for rupture (blast). The general build and nutrition should also be noted—for example, whether the patient is short and fat, tall and thin.

Loss of Fluid

A close watch should be kept on loss of fluid from the body by haemorrhage, sweating, vomiting, and the passage of urine and faeces. When possible the amounts lost in this way should be measured. Thirst and nausea should also be noted. An attempt should be made to estimate fluid lost from the circulation into the tissues—for example, when blistering is extensive or when the limbs become swollen. In the latter case the swelling of the limbs may be estimated by measuring their girth or by noting displacement when immersed in water.

Haemorrhage.—It is difficult and often impossible to estimate how much blood has been shed. The colour of the skin and mucous membranes is of little value, as they may be rendered pale by local vasoconstriction or by drainage of blood to other parts of the body. The usual methods of estimating circulating blood volume (dye or carbon monoxide methods) are not readily applicable to severely injured patients. An indication may be got, for example, from the state of the dressings, by measuring the amount of blood lost at operation, by soaking dressings, etc., in water and subsequently noting the volume of water and estimating its haemoglobin content. Some indication also may be obtained from the state of the blood. Thus the estimation of the haemoglobin and the red cell number or volume (haematocrit) before and after the administration of plasma may give an approximate idea of the circulating blood volume. A single estimation of the haemoglobin content of the blood is of little or no value for showing the amount of blood lost from the circulation; of greater value is a series of readings which may reveal a progressive dilution or concentration of the circulating blood. In this connexion it is important to note the method used for estimating haemoglobin, the site from which the blood sample is drawn, if much squeezing or venous congestion is required to obtain a flow of blood, and if the finger or ear is cold. It is said by some that a concentration of the blood is an early and valuable sign of "shock"; on the other hand, others say that many cases regarded as "shocked" show no evidence of blood concentration, while some claim that concentrated blood may be found in the cold extremities of normal subjects.

Sweating.—The amount of fluid lost from the body by sweating may be considerable. Its outbreak, degree, and cessation should be noted. Sweating may be associated with a pale skin as in "shock"; associated with a hot flushed skin it may indicate that the patient is being overheated.

Thirst, Nausea, and Vomiting.—Thirst should be noted; it is often severe, especially when dust has been inhaled. Nausea and vomiting are frequent; the amount and character of the vomit should be noted. Undigested food may be vomited hours after injury. Nausea and vomiting may be associated with either a rise or a fall of pulse rate and blood pressure.

Urine and Faeces.—The passage of these should be noted. Many patients do not pass urine until fifteen to thirty hours or more after injury, and the urine then and for a time subsequently often contains albumin, blood, and casts. The anuria does not seem to be necessarily associated with low blood pressure or severe injury; further observations are required. When facilities are available other urinary investigations should be undertaken. For instance, estimations of blood urea are of interest.

Observations on the state of the circulation are regarded as of chief importance in the condition of "shock," and much information may be gathered from observations on the blood pressure, pulse rate, and skin colour and temperature.

Blood Pressure

Blood pressure is regarded at the moment as one of the most important guides to the patient's state and progress;

Diagram of apparatus used in taking serial blood-pressure readings.

serial readings are essential. The frequency of readings depends on circumstances: they may be required every five, ten, or fifteen minutes in the early stages, or at hourly or longer intervals in the later stages. A respiratory variation in blood pressure is often present, the pressure rising with expiration and falling with inspiration.

For serial readings it is of great help to use a modification (see diagram) of the auscultatory method usually employed. A flat stethoscope diaphragm D having the exit tube bent parallel to the diaphragm is incorporated in the inner and lower edge of the sphygmomanometer cuff C. An aluminium strip A ($1/32'' \times 3/8'' \times 4''$), suitably bent and stitched to the cuff and exit tube of the diaphragm, holds the latter in position on the cuff. If the rubber bag R comes close up to the end of the cuff it is necessary to add another piece of cloth to accommodate the diaphragm. A rubber tube B, 6 inches long, is attached at one end to the diaphragm and at its other bears the female part of a male-and-female metal junction. The male part of the junction is inserted into a rubber tube E, 18 inches long, at the other end of this tube a metal Y-piece receives the two rubber tubes of a binaural stethoscope. The rubber tube F of the sphygmomanometer cuff is cut to 6 inches in length and bears the male part of another male-and-female metal junction. (The second tube from the cuff, if present, is cut short and sealed, not being required.) A rubber tube G, 18 inches long, bears the female part of the metal junction at one end; at the other it connects through a metal Y-piece with the manometer and pressure bulb. The diaphragm is placed and held over the brachial artery above the elbow, while the cuff is applied in the usual manner and fixed by a buckle. The stethoscope and manometer are connected by the rubber tubes. Readings may then be taken no matter what the position of the patient's arm. This method avoids the necessity for disturbing the patient by repeatedly exposing an arm, and readings may be made even during sleep. It is more convenient to use an aneroid than a mercurial manometer, particularly when blood-pressure observations are made in the operating theatre, thus avoiding the necessity for a stand for the manometer in a space already sufficiently occupied by surgical staff and instruments. The length of tubing allows the observer to stand at some distance from the patient. With this modification, also, the pulse rate may be counted by inflating the cuff till the pulse becomes audible and maintaining the pressure for the quarter-minute or half-minute necessary.

It is of advantage to have several cuffs, with the diaphragm incorporated, so that observations can be made on more than one patient, leaving the cuffs on the arm and disconnecting stethoscope and manometer at the junctions.

Pulse

In addition to the rate, the rhythm and quality should be noted. Irregularities in force and rhythm are often encountered as transient phenomena in air-raid casualties. Alternation, sinus arrhythmia, extrasystoles, and fibrillation have all been met with. Where a portable electrocardiograph is available records would be of interest. A point which has been noted is that though in some instances the radial pulse is hardly palpable the blood pressure may be within normal limits or be raised. The observations on pulse and blood pressure are important because they are used as a basis for judging the patient's progress. It is said by some that a rising pulse rate indicates improvement, and by others, on the contrary, that it indicates deterioration. Both may be true, depending on the circumstances. A rise of pulse rate and a fall of blood pressure may indicate that a cold patient is becoming warm or that haemorrhage is taking place. It is to be remembered that 1/100 grain of atropine may considerably increase the pulse rate.

Skin Colour and Temperature

It is important to observe closely the phenomena displayed by the skin, and how these change with the passage

of time. Note the colour of the skin, whether it is pale or flushed, and whether the tint is a normal pink or is cyanotic. It is to be remembered that cyanosis is not easily recognized in artificial light, especially if this is dim. For the observation of colour it is of advantage to carry a torch giving a white light. It is to be remembered also that pallor or greyness of the face may be due only to a coating of plaster dust, the pale tint being enhanced by smears of blood on the face.

Skin temperature is particularly useful in assessing the state of the peripheral circulation: a cold skin indicates poor, a warm skin good, peripheral circulation. It is not necessary to estimate skin temperature by a thermometer; it is sufficient to record whether the skin feels cold, cool, warm, or hot to the observer's hand. The observer's hand should be warm. Note where the skin temperature is taken, because it is only in the hands and feet, nose and ears, that skin temperature is a good index of the skin blood-flow. On the trunk, forehead, and muscular parts of the limbs the skin is warmed mainly by underlying structures, and skin temperature may be high although skin circulation is at a standstill. The extremity of which the skin temperature is noted should be exposed to room air: a hand withdrawn from under a heated cradle may be warm without the warmth indicating a good peripheral blood-flow. The nose, or the hand of an arm exposed for transfusion, is a convenient site for watching changes in skin temperature. It will be found, for example, that low blood pressure is usually accompanied by pallor and coldness of the skin: as the blood pressure rises the skin becomes pinker and warmer. In certain instances, however, the exposed hand may remain warm although blood pressure falls. The onset of a rigor is often preceded or accompanied by the appearance of pallor and a drop in skin temperature. It is to be remembered that evaporation of sweat cools the skin surface.

Body Temperature and Respirations

Estimations of temperature in the mouth or axilla are very liable to error, and it is best to note rectal temperature. Remember that a patient may be thoroughly chilled by exposure and may require prolonged heating to become comfortably warm, although his body temperature may have been but little or not at all lowered. Rectal temperature is the best guide to blood temperature.

In addition to rate of respirations, the depth, regularity, etc., should be noted. Cheyne-Stokes respiration should be looked for. Attention should be paid to the development of abnormal signs in the chest (collapse, oedema).

Handling the Patient

Details of the handling of the patient should be recorded. Notes should be kept, for example, of when the patient is undressed (whether or not the clothes are cut off), moved from stretcher to bed, taken to the theatre, and examined surgically. The method of warming by cradle or electric blanket should be recorded, also the time of application and of the withdrawal of heat. Note, too, when the end of the bed is raised and how much, and when it is lowered. The effect of handling should be observed—whether or not blood pressure or pulse alters, or pallor or sweating develops.

There is considerable difference of opinion on how best to handle patients. For example, in some hospitals it is the general rule, as soon as possible after admission, to transfer the patient from stretcher to bed, to undress him, cutting the clothes off if necessary, to examine him completely, and then allow him to rest while being warmed. At other hospitals it is the custom not to undress the injured patient until he is in the operating theatre and under the

influence of an anaesthetic. Data are wanting by which the relative value of the different methods of handling a patient can be assessed.

Treatment

In addition to such points as have already been mentioned note should be kept of all drugs given, the dose and time being recorded—for example, A.T.S., morphine, atropine, oxygen, sulphanilamide. A record should be kept of all fluids administered, whether by mouth, rectum, or vein. When blood or plasma is given the rate of transfusion should be noted. Any difficulty in entering a vein with a needle or cannula or of getting the fluid to enter the vein should be recorded. Note the temperature of the fluid administered: rigors may follow the intravenous administration of cold fluids. It is of value to note whether varying the rate of transfusion appreciably alters the patient's state. It has been found, for example, in some cases that blood pressure falls when the rate of transfusion is reduced; in others that nausea, restlessness, and respiratory distress accompany speeding of the transfusion.

Operative treatment, the anaesthetic employed, and the progress of the patient while he is in the operating theatre and subsequently, all require description. An attempt, too, should be made to follow the progress of the patient if he is transferred to another hospital. In the event of death the manner of death should be recorded and every effort be made to obtain a post-mortem examination. Fat emboli should be looked for.

It is of value also if during the course of the case and at the end the observer gives his general impressions. For example, he may state that judging by the rise of blood pressure the patient now seems fit for operation; that the case appears to be one mainly of loss of blood; that he is surprised at the turn events have taken. In this way he is led to learn from his observations and to look for further evidence in future cases to support or correct his impressions.

Medical Memoranda

Sulphonamide in the Treatment of Corneal Ulcer

Sulphonamides have in recent months been used locally in various surgical and skin conditions. The suggestion arose to try this method in seriginous ulcers of the cornea, and since October, 1940, we have treated these cases with prontosil applications. The following preparation was used:

Prontosil soluble 5% 5 c.cm.
Paraffin. mollis ad 1 oz.

It was inserted into the conjunctival sac twice daily for prolonged periods. No other disinfectant was used.

In judging the results of any treatment of seriginous ulcer it has to be borne in mind that we are dealing with a disease which has to be attacked from several sides, since almost always there are complications, with their special features and dangers, which may influence the course of the disease. Iritis, invariably present, has to be held in check by mydriatics and by the application of heat; increased ocular tension often necessitates surgical intervention in the form of paracentesis; a diseased lacrimal sac has to be excised.

In any given case it is difficult to say to which of the various factors of treatment success or failure has been due; and it will be understood, since prontosil replaces only one of the weapons used, that a conclusion as to its efficiency can be arrived at only by comparing a series of cases in which it has been used with a corresponding series in which other anti-bacterial agents have been employed.

COMPARISON OF RESULTS

Two series of cases are considered: (1) the prontosil series, comprising all patients so treated who have been discharged from hospital two weeks or more; and (2) the "previous" series, consisting of the first 20 cases of seriginous ulcer treated in 1940, in which either argyrol or mercurochrome had been used. The latter series contains a number of cases in which the cautery had been employed, when the ulcer could not be prevented from spreading. No form of cautery, chemical or heat, has been used in the prontosil series, but in 9 cases treatment was supplemented by local irradiation with ultra-violet light (Duke-Elder's mercury vapour lamp). This subsidiary treatment was chosen for two reasons: (1) In cases in which the ulcer did not come to an early standstill it did not seem justifiable to resort to an experimental drug only. (2) On theoretical grounds local irradiation appeared well fitted to supplement the bacteriostatic action of the drug. Since ultra-violet light acts more in the nature of stimulating the tissue to anti-bacterial activity than as a direct bactericide, it only partly overlaps the effect of prontosil.

The table shows that the results of treatment with prontosil, as judged by the visual acuity remaining when the ulcer had healed, compare favourably with those of the orthodox treatment. The most striking feature of the prontosil series was the transparency of the resulting scar of the cornea, even in many cases in which the infiltration had gone very deep into the corneal tissue. Perhaps this was mainly due to the fact that the cautery was never

Visual Acuity of Affected Eye on Last Visit to Out-patient Dept., with Refraction Corrected	Prontosil Series	Previous Series
6/6 or better	6	1
6/6 to 6/18	7	8
6/18 to 6/60	5	3
Less than 6/60	2	6
Eye lost	0	2

required to arrest the spread of the ulcer. The rapidity of healing was the same in the two series, the average period of in-patient treatment being 10½ days in each.

Summing up we would say that the results of treatment of seriginous ulcer of the cornea by the application of prontosil ointment are encouraging, especially when used in conjunction with local ultra-violet light. It might prove a valuable addition to our therapeutic weapons against this dangerous affection of the eye.

We would like to express our thanks to Mr. Alexander MacRae for allowing us to treat these cases and for his encouragement and advice.

House-surgeon, Newcastle-upon-Tyne Eye Hospital

Renal Complications of Sulphapyridine

After reading the article by Mr. Leedham-Green (*Journal*, 1941, 1, 586) I am prompted to record the following case.

CASE REPORT

The patient, a boy aged 5, had had three attacks of tonsillitis during last winter. Two of these were followed by mild otitis media, the first attack being treated with sulphanilamide. The second attack occurred a week after the tonsillitis, and as there was considerable injection of the malleus region of the ear-drum, with a temperature of 101°, I decided to give sulphapyridine. He had an initial dose of 1 gramme in the morning. About four hours later he began to vomit, and vomited several times during the afternoon. He refused to take fluids on account of the vomiting which they almost immediately initiated. He passed no urine from about midday until evening, when a small quantity was voided; this was not measured and was not seen by me. That evening he seemed better, but as the temperature was 99.6° another 0.5 gramme of sulphapyridine was given, also a small drink of water—all he would take.

The next morning he complained of abdominal pain centred round the umbilicus and spreading laterally towards the flanks. He vomited about 6.30 a.m. and again shortly afterwards, and voided a small quantity of thick cloudy urine, which was not

saved for me to see. I examined him about 8 a.m. for the abdominal pain, and thought it was probably colic, as he had had no bowel action the previous day. His ear-drum looked better and his temperature was normal. He was given an enema with a good result, but so far as could be ascertained he passed no urine. The enema relieved his pain, and he seemed better. He had had an appendicectomy at the age of 12 months, so appendicitis was ruled out. Nothing of note could be felt in his abdomen, and no loin tenderness was observed.

At 2 p.m., after voiding no urine since 6.30 a.m., he passed about half a pint of very heavily blood-contaminated urine, almost pure dark blood; I saw this, but through a misunderstanding it was thrown away. About an hour later he voided 6 oz. of urine; this was very much better, but it still contained obvious macroscopic blood. Laboratory examination showed red blood cells only; no casts or crystals were noted. About 5 p.m. I catheterized him. Macroscopically the specimen contained only faint blood; microscopically red blood cells were seen, but no casts, and a culture was sterile. He had been drinking well all day, had had no pain since early morning, and his temperature was normal. He continued voiding urine with progressively less blood, and the last night specimen, about 10 p.m., was only very faintly hazy.

The next morning his urine was crystal clear and chemically contained no albumin. For the rest of the week it remained the same, fluids being forced, but no more specimens were microscopically examined. Beyond looking rather pale for a week, during which time he was kept at rest, he has remained perfectly well, and a subsequent radiograph (plain abdominal) revealed no opaque calculus in the whole renal tract.

The diagnosis seemed initially to rest between sulphapyridine haematuria, acute haemorrhagic nephritis, and renal or vesical calculus. The sudden onset of haematuria, with abrupt clearance of the urine within twenty-four hours, and the complete absence of casts made nephritis very unlikely. No opaque calculus was seen radiographically, and he had never had any symptoms of calculus.

COMMENTARY

The interesting feature is the onset of haematuria after 1.5 grammes of sulphapyridine. This I am inclined to think was caused by the dehydration produced by vomiting and the inability to take fluids. Tsao *et al.* (1939) pointed out that the dosage does not seem to be an important factor. Their lowest dosage totalled 3.5 grammes in a child of 11 years. All that is necessary in a mild case such as the above is the withholding of sulphapyridine and the forcing of fluids to dissolve the concretions, which are composed of acetyl-sulphapyridine, and which are readily soluble in water. In severe cases of anuria, with complete ureteric obstruction caused by concretions which lodge mainly in the ureteric orifices of the bladder—that is, cases of calculous anuria, the calculi being composed of acetyl-sulphapyridine—the treatment has been to insert ureteric catheters up to the kidney pelves and actually to lavage the pelves and ureters with sterile water or saline until the concretions have dissolved.

Carroll *et al.* (1940) and Sadusk *et al.* (1940) reported two such cases that were cured by this means, although one patient died later from the cerebral injury for which he was given sulphapyridine. The pyelograms which they publish tend to show that it is not the ureteric orifices alone which are affected, but that the whole collecting apparatus—calices, pelves, and ureters—is full of concretions, which cause a very poorly defined radiograph of the renal pelves, etc., after injection of the pyelographic media through the catheters. Following lavage for half an hour or more a clear picture is obtained, and the urine, which after insertion of the catheters emerges very scantily and heavily blood-stained, quickly clears and appears almost normal in colour. It also drops rapidly from the catheter. Hence it seems necessary not only to insert catheters up to the renal pelves, as was originally suggested by Tsao *et al.*, and mentioned by Leedham-Green, but, in addition, to wash away these soluble concretions by repeated lavage.

Reviews

WARTIME FEEDING

Food Values in War-Time. By Violet G. Plimmer. (Pp. 80. 1s. net.) London, New York, Toronto: Longmans, Green and Co. 1941.

Mrs. Plimmer has turned her wide knowledge of food and diets towards the solution of the difficulties of wartime feeding. Our information on food values is far greater to-day than it was during the last war, and if only we were intelligent enough to accept and apply the recommendations made by the people who know about these things we should be in a better physical condition at the end of the war than we were before it. Unfortunately many people look upon these recommendations as merely war measures, and will return to their previous diets as soon as possible. Mrs. Plimmer's book seeks to explain these recommendations and does so clearly and forcibly. We are left in no doubt as to why wholemeal and even the national wheatmeal bread are better than white bread. It is deplorable that such a large proportion of the public refuses to give up white bread that the Government has to help that part of the public in spite of itself. Vitamin B₁ and extra calcium will be put into white flour, but this cannot make it equal to wholemeal, which contains in addition vitamins B₂, A, and E, essential minerals, and better proteins. Mrs. Plimmer's plea throughout her book is for whole foods, which may be ground as finely as one may wish, but nothing must be taken from them. No addition of vitamin concentrates (least of all the pure or nearly pure ones) can make up for what is taken away in certain processes of manufacture, for we do not yet know every constituent of the parts removed, and some of them may be at least as important as those we know. Only one sentence in this book would we change. For "What the civilian loses in protein he gains in vitamins and minerals" (p. 39) we would substitute, "The civilian loses in protein but gains in vitamins and minerals," and on page 68 the word "variable" should come after the vitamin D content of butter, not of margarine, for the vitamin D content of all margarine nowadays is far more constant than that of butter.

The whole book is most readable and instructive, and concludes with some valuable tables of amounts of various foods which on the average will supply the necessary daily amounts of each of the vitamins. It is worthy of a better binding, but that would have made it more expensive and probably therefore have restricted its distribution.

SURGICAL ASPECTS OF HEART DISEASE

Surgery of the Heart. By E. S. J. King, M.D., M.S., D.Sc., F.R.C.S., F.R.A.C.S., Major A.A.M.C. (Pp. 728; illustrated. 50s. net.) London: Edward Arnold and Co. 1941.

Books and journals devoted to the study of heart diseases from the medical point of view are abundant, but those dealing with the same subject from the surgical aspect are few and far between. For this reason *Surgery of the Heart*, by E. S. J. King of Melbourne, is a notable monograph. Its matter consists of an expansion of the Jacksonian Essay submitted to the Royal College of Surgeons of England in 1938. In the preface the author explains that the contents include observations made on pathological material collected over a period of several years, experimental work carried out during the last four years, and clinical cases, some of which were treated a number of years ago but the majority being relatively recent. Study of the book reveals that a more descriptive title would have been, "Diseases

of the Heart from the Surgical Aspect," for here is as complete an account of the development, anatomy, histology, physiology, and pathology of the organ as is to be found in any purely medical treatise of corresponding size. In addition the chapters on the examination of the heart include extensive accounts of orthodiagraphy, teleroentgenography, kymography, tomography, and electrocardiography. It is perhaps rather unfortunate that the same word "kymography" is used to describe both the new method of x rays through a moving multiple slit grid, and also the ordinary physiological pressure curves in the blood vessels. Possibly, in view of its derivation, the term would be best applied to the "comb"-like tracings made on the x-ray film; but, on the other hand, custom has for long accepted the common physiological usage. To find, however, two utterly dissimilar illustrations both described as kymograms within a few pages is certainly distracting.

In the section on coronary occlusion we were surprised to find so little description of the actual technique of the various operative procedures attempted for its relief. Had this been a medical instead of a surgical treatise we should still have expected a rather fuller account of the surgical details. Cardio-omentopexy, for instance, introduced by Beck and elaborated by O'Shaughnessy, is mentioned, but the surgeon must look elsewhere for any guide as to the performance of the operation. Even the author's own method of introducing bone dust into the pericardium, to induce adhesion formation and so reinforce the failing blood supply to the heart wall, is given but a scanty description, though an illustration of an injected specimen six months after this operation conveys an impressive picture of the degree of collateral circulation thus produced in the myocardium. We agree, of course, that it would be a mistake to overload a book of this kind with operative detail, and acknowledge that "surgery" is a much bigger thing than the mere performance of operations, yet at the same time the essence of surgery is technique. In a book as generally excellent as this monograph and with such a title it might have been advisable to devote more space to this aspect.

At the end of each chapter there is an exemplary bibliography which we believe records every significant article that has been written on the particular subject. This alone indicates a very great labour, for which many will be grateful to the author. Despite certain criticisms, therefore, which are not meant to be destructive (for we hope the book will reach further editions in which its general scheme can be modified), *Surgery of the Heart* is likely to become the standard book on the subject. It is one which every surgeon aspiring to cardiac work should study, for not only will he find it very informative but it will also help him to careful judgment by its sanity of outlook.

FAITH HEALING

Priest or Physician? By George Godwin. No. 10 of the Thinker's Forum. (Pp. 44. 6d.) London: Watts and Co. 1941.

To-day it would be impossible for the publication of Mrs. Humphry Ward's *Robert Elsmere*, with its Arnoldian dictum "Miracles do not happen," to arouse the furore it did in the 'eighties. On the one hand Christianity is no longer regarded as rooted in miracles, and on the other there is now a much better comprehension of the interaction of mind and body. Any argument in favour of the "miraculous," so far as it is not based on mere obscurantism, comes from a different quarter: the philosophic criticism of causality and recognition of the fact that Nature is not nearly so tidy as the human mind would like her to be. Yet there remains substance in Hume's observation that "it is contrary to experience that a miracle be

true, but not contrary to experience that testimony should be false." To which Sir R. Burton added the pertinent rider that if Hume had lived in the East he would have come across so many miracles that he would have been even more incredulous!

In this pamphlet the author briefly surveys various stories of miraculous healing through the ages, and concludes that faith-healing cults arise from an instinctive reaction to psychological laws without any similar understanding of the laws themselves. Every faith cure is amenable to a rational explanation. The most modern technique of the healing art is really a scientific growth out of the old art of faith healing: suggestion, catharsis, the analysis of dreams, etc. Psychotherapy is in fact the oldest form of healing we know, whether it be applied without knowledge of underlying principles by priests in temples or by men groping on the edge of that vast uncharted realm, the unconscious mind.

We would present the author with an argument he does not use. Even organic ills have a penumbra of functional symptoms; disuse breeds incapacity, which can be greatly alleviated by psychotherapy whereby the lame and palsied can be made to walk again. It is to be hoped that this little book will be widely read, for there is still much opposition to be encountered.

PRINCIPLES OF PHYSIOLOGY

Starling's Principles of Human Physiology. Edited and revised by C. Lovatt Evans, D.Sc., F.R.C.P., F.R.S. Eighth edition. (Pp. 1,247; illustrated. 32s. net.) London: J. and A. Churchill, Ltd. 1941.

Starling's Physiology was first published in 1912, and since then has passed through seven editions. It has been translated into Spanish, a language of increasing importance in the modern world. Those who were brought up on Starling will have a warm feeling of satisfaction in knowing that their old favourite is still upon the stage, acting its part, indeed, with renewed vigour. The eighth edition, recently issued, is the fourth that has been prepared by Prof. C. Lovatt Evans, Starling's successor in the Jodrell Chair of Physiology at University College, London. In his preface he states that the quick change of events in the world of physiology and the vast accumulation of published matter have inevitably made it impossible to keep "that ample and leisurely atmosphere which was so attractive a feature of the earlier editions." In these hard-pressed times, when technology reigns supreme and human beings seem to be doing their best to earn the appellation of Yahoos, we may share Prof. Lovatt Evans's implied regret for the days of leisure in which the broad idea and the wide generalization found easy expression. We live in a period in which the material world is being analysed with a boldness and vigour that bring us unexampled power over Nature. What a distance, for example, physiology has gone since Wöhler synthesized urea in 1828! The synthesis of vitamins and hormones is now taken as a matter of course. These are startling new achievements, but the fundamental discovery that an organic substance can be synthesized without the intervention of a vital process was made over a hundred years ago. Most of the modern advances that have been made might best be described as tactical. The broad strategy was laid down by the pioneers, of whom Starling was one.

Prof. Lovatt Evans has faced the problem squarely and done his task of revision with admirable skill. The section on the central nervous system has been entirely rewritten, the part dealing with reproduction has been extensively altered, and much new matter has been included in the sections on the endocrines and on the vitamins. Prof. H. Hartridge has revised the section on the special senses

In spite of much pruning and rearrangement the text has been increased by 139 pages over the last edition, and there are 118 new figures. The publishers are to be congratulated on the way they have helped the reader by the use of headings and an easily legible type, and upon the excellent reproduction of the illustrations in line and half-tone. That such a volume should be published in the second year of the war is a high tribute to both editor and publishers.

Notes on Books

The Voyage of the Cap Pilar, by ADRIAN SELIGMAN (Hodder and Stoughton, 2s. 6d.) is in no sense a medical book, but it will appeal to many doctors. Those who love the sea, admire the spirit of adventure, and those who were fortunate enough to take part in the "Round the World" tour of the B.M.A. in 1935 will enjoy the book. To most of us there is an ample spirit of adventure in embarking on the sea of matrimony. Add to this the purchase of a sailing ship of 259 gross tonnage with the decision to take a honeymoon of two years' sailing round the world with a crew of amateurs, and the reader will have a good idea of the contents of this book. It is clear from the outset that the gods look with favour on this revival of the Elizabethan spirit of adventure. There is a remarkable absence of record of illness and accident, and the party arrived safely home in the third week of September, 1939. We miss the beautiful photographs of the original issue.

A Laboratory Manual of Physiological Chemistry (4th edition), by Prof. D. WRIGHT WILSON of the University of Pennsylvania, is a manual designed for use in medical, dental, and veterinary courses. The volume of 298 pages describes a very extensive series of laboratory exercises in the subject. It is published in this country at 14s. by Baillière, Tindall and Cox.

Prof. T. W. M. CAMERON's textbook, *The Parasites of Man in Temperate Climates*, was favourably reviewed in these columns on May 10 (p. 711). The publishers in this country are the Oxford University Press, and the English price is 18s. 6d.

A Textbook of Physiology, by WILLIAM D. ZOETHOUT, Ph.D., and W. W. TUTTLE, Ph.D., has now reached its seventh edition (London, Henry Kimpton, 22s. 6d.). This work is intended to fill the gap between the larger textbooks and books of a quite elementary character, and to be used by students with from 50 to 150 hours to devote to the subject. In the present well-revised edition the authors express the hope that "the reader will find this text to be a clear, logical, and concise account of the facts of physiology as they are recognized to-day." In the opinion of the reviewer they have succeeded in their aim. The book should be useful to students working for the Conjoint, and for examinations in pharmacy, domestic science, etc. It is as detailed as need be, and keeps the facts of medicine and everyday life well in mind.

Dr. F. M. R. WALSH's book, *Diseases of the Nervous System Described for Practitioners and Students*, was very favourably noticed in our issue of November 16, 1940, and the review ended: "As an introduction to clinical neurology this small volume has few equals, and as a useful handbook for the practitioner it can be highly recommended." A second edition has already appeared (E. and S. Livingstone, 12s. 6d.). Changes and brief additions to the text have been made in accordance with suggestions of colleagues and other readers, and the discussion of certain subjects has been expanded without departing from the original plan and scope. There are also some new diagrams and photographs. We foresee a continuing demand for this straightforward guide to the commoner diseases of the nervous system.

There are occasions when people unconnected with the Press are in need of accurate information about some newspaper or other periodical; they will find what they require briefly set out in *Willing's Press Guide*, of which the sixty-eighth annual issue is published at 5s. by Willing's Press Service, Ltd., 356-364, Grays Inn Road, W.C.1. Care has been taken to keep pace with the very large number of changes brought about by war conditions.

Some periodicals have disappeared from the list because of temporary suspension of publication, and others have been merged or now appear less frequently than usual; others, again, are being produced from evacuation addresses.

Preparations and Appliances

EYE AND MASTOID BANDAGING: LOOPED-CAP SYSTEM

Captain ERIC COPLANS, R.A.M.C., writes:

The existing method of bandaging is, in my view, open to criticism. The pressure of the fixation bandage (round the temple) causes headache and distress; this may be due to pressure on the supraorbital nerve. The bandage often slips down over the uninjured eye or up the head and needs adjustment. It takes a whole bandage and safety-pins.

The loop system consists of a skull cap of strong, washable linen or calico. Around the lower band, which should be a 2 in. hem, is placed a series of vertical loops 1½ in. high. Figs. 1 and 2 show the position of these loops (tape): one front central (A); two front, 4 in. apart, each 2 in. from centre (B); two back central, 4 in. apart (C); one each side of head (D).

The procedure is as follows: Cut off 1½ yards of 3 in. roller bandage. Adjust looped cap to patient's head. To bandage the right eye, thread the end of bandage twice through the loop

FIG. 1

FIG. 2

FIG. 3

FIG. 4

over the left eye—draw taut (tying or safety-pins unnecessary). Draw bandage across bridge of nose, over right eye, down below right ear to back of head. Thread through back loop (Fig. 2) and return back below ear up to the front central loop. Thread and repeat, finishing at original starting loop.

The ear, mastoid region, and jaw are bandaged by choosing appropriate loops. If it is desired the hem or band can be cut and tapes attached for adjustment to any size head.

It is hoped that this will prove in the hands of others a method of rapid and complete fixation of eye, ear, and face bandaging with considerable economy of bandage. In the photographs (Figs. 3 and 4) the upper part of the looped cap is "windowed" because the experiments were conducted in the Tropics.

BRITISH MEDICAL JOURNAL

SATURDAY SEPTEMBER 6 1941

FUTURE OF MEDICAL EDUCATION

In the present upheaval, which is changing social conditions more than any event since the Black Death, the future of medical education becomes a problem as difficult as it is important. Prof. John Ryle in his stimulating and thoughtful article published this week poses the fundamental question, How can medical education be improved so as to help to develop a breed of doctors better blessed with humanity and judgment with simultaneous gain rather than loss to their scientific sense? For there has been a tendency, in return for the rapid contributions of the sciences, for medicine to sacrifice its position as a cultural profession. Its philosophy has not kept pace with technical achievement. How can this best be remedied?

To start at the beginning—the tendency is to begin specialized studies too soon, yet without an adequate introduction. Not only the Regius Professors at Oxford and Cambridge but outside bodies have urged that biology should be a subject of general education. A better world can be built, physically and psychically, only on a sound biological basis. All should know the laws of being, for Nature has no mercy for ignorance. Although adults often seem to have or to acquire a curious lack of interest in such matters, the child has unbounded curiosity about life and its origins. Here is a door wide open for the reception of biological teaching by all school children. As Prof. Ryle truly says, there is no subject more important as a proper introduction to the later understanding of man and his problems and of healthy citizenship. Moreover, it would provide some indication of the boy's vocational inclination. Yet the boy destined for medicine who has passed his School Certificate is brought abruptly to its study and finds it strangely different from the rest of his work. Inevitably he flounders at first and wastes time in a way which could thus be avoided. It would also enable general education to go on concurrently with preparation for the First M.B., which should not be taken before the age of 18. That is quite young enough to start work in the dissecting-room; indeed, a year later is preferable.

Too often the teachers of the pre-medical and pre-clinical subjects seem to forget that they are training students the great majority of whom are going to become medical men and not laboratory workers. Then they tend to rationalize by drawing a sharp and really unjustifiable distinction between education and vocational methods of training, for these are by no means incompatible. What the medical student needs is a training in the principles of chemistry, physics, and biology rather than an accumulation of facts. The teachers

maintain that general principles are the last thing the student can appreciate, and they have Bacon's opinion on their side. Intelligent students, however, deny this contention. Considering that the practice of medicine touches life at all points it should not be impossible to give a vocational trend to the whole of a student's education without impairing its intellectual value.

If dissection of the whole body is to be insisted upon emphasis should surely be laid on those parts which will repeatedly come into the student's ken later on, when the complex connexions of the otic ganglion, for instance, will assuredly fade into the background. The anatomy of the living is fortunately receiving increasing attention through the application of x rays and other means. The study of structure and function should be more closely related. Physiology is becoming highly abstruse, and it would be well if in addition to insistence on general principles emphasis were laid more on human physiology, which could be illustrated by the stethoscope, electrocardiograph, sphygmomanometer, and so on. Everything should be done to minimize the breaks which still exist between the different stages of the student's career. It is still the exception rather than the rule in the physiology course to illustrate sensory tracts by showing cases of tabes or syringomyelia, while a patient with hemiplegia will impress the student with the functions of the upper motor tract more than any sections or diagrams. These things are generally agreed, and it is chiefly due to lack of co-ordination and co-operation that they are often not carried into effect. The Universities' Committee for the revision of the curriculum advocated some elementary lectures on normal psychology before going on to abnormal, just as the student proceeds from physiology to pathology. Admittedly a psychologically normal man is a mathematical concept based on a series of superposed mental photographs, as it were. By the psychology of the normal we do not mean academic psychology, which is so remote from the medical student's needs that it may easily deter him from taking any further interest in psychology at all. Medical psychology has, however, worked backwards from full-blown psychoses and neuroses to arrive at certain general conclusions on the nature of the emotions, rationalizations, mental development and regression, and so forth, sufficiently to be able to present working hypotheses which can be correlated with the teaching of the physiology of the central nervous system and special senses. Prof. Sigerist has recently urged that, although disease is a biological process, when it occurs in man it always involves the mind. Clearly it is more important for the student to know something of the working of his patient's mind than to memorize the *materia medica* he will never have to handle directly. In this way the student on entering the wards will be more prepared to regard his patient as an individual and to view his case as a whole. It is the particular merit of the British system of clinical instruction that this attitude is encouraged from the outset, and the student, after long communing with the dead, is usually eager to come at last to terms with the living. There is much to be said for Prof. Ryle's contention that in-patient medical clerking should be the first clinical appointment, though naturally after a preliminary course

of instruction on methods of examination and physical signs. The more popular method of pitchforking the student into the turmoil of the surgical casualty department may have the advantage of proceeding from the simpler objective examinations to more complicated studies, but lacks the mental training derived from thorough and quiet investigation in the wards. It is essential that he should be impressed with the vital importance of pressing the purely bedside methods as far as possible before the aid of the laboratory and other such departments is sought. There are difficulties, we are aware, in the way of a closer association between pathology clerking and clinical clerking, but it is a bad practice to keep a student doing blood counts and the like on cases he never sees; no wonder he feels it is a meaningless routine. It is the pressure of preparing a case for the visiting staff that leads to a rush of multiple investigations being made as soon as possible after a patient's admission, but it is having a most pernicious influence on the whole mental approach of the student to his patient. It is no exaggeration to say that this lies at the root of much of the dissatisfaction with the present results of medical education. After all, the student is influenced by deeds rather than words, and when he sees his house-physician busily engaged in signing "path. forms" he draws his own conclusions, and attaches more importance, for instance, in a case of jaundice to a van den Bergh test than to inspection of the urine and faeces.

Systematic lectures are out of favour: the word "lecture" tells its own history of a mere reading from authorities when books were scarce. Now books are abundant, but increasingly expensive and soon out of date. Lecture-demonstrations on cases are always preferred, and if these are supplemented by advice as to reading, together with a copious supply of current textbooks which could be taken out from the library for limited periods, the need for systematic lectures would disappear. On the other hand, tutorial classes in which the student is asked questions are valuable and should be retained. The student should be able to ask questions in return. The cost of books is only one, though an important, item in the student's expenses. Indeed it seems that when about 45% of university students are in receipt of State grants it is only fair that students in medical schools should also share in these. In this way the path of able students from whatever class would be smoothed. If this involves raising the standard for entrance, so much the better.

Students are becoming more vocal in their criticisms, and this is not always welcomed by the teachers. Yet it is democratic, and reasonable representations should be received in a reasonable spirit. The good sense of the general body of students can then be trusted to see that the privilege is not abused. A student's journal recently abandoned dreary dissecting-room jokes for the nonce and published some useful impressions from its own members of the various courses of instruction. After all, the subject is of vital importance to them, and for that reason we have invited a contribution from Mr. Donald McDonald on the future of medical education from the student's point of view, which should be of interest to the teachers.

INFECTIOUS DISEASES IN WAR

War seems always to have been attended by an increase in the prevalence of disease. Spread of infection may be expected to occur when there is concentration and movement of large bodies of men from various parts of the world. Fatigue and hardship, malnutrition, famine, and exposure, lack of medical care, of sanitation, and of personal hygiene, all provide conditions that are ideal for the explosive outbreak of widespread epidemics. Refugees and captured—perhaps especially returned—prisoners are important instruments in the transmission of disease among troops and civilians alike. The factors governing the spread of infectious disease in war are, however, very complex: certain of them have recently been considered by Clara E. Councell,¹ with special reference to events in the present war and in that of 1914-18.

Apart altogether from wars some diseases are known to show a periodic prevalence. Thus it has been suggested that the spread of virulent small-pox throughout Europe after 1870 cannot be explained wholly by the events of the Franco-Prussian War. In the same way the prevalence of influenza in 1918-19, and of cerebro-spinal meningitis in the same years and again in 1939-40, may be interpreted as evidence of a wave in epidemicity that would have manifested itself in the absence of any contributory factors present in wartime. It is, however, obvious that usually mild diseases may flare up with unparalleled activity as the result of abnormal circumstances of living. In wartime, too, owing to the similarity in symptoms of certain infections there is often a tendency to confound two or more diseases. Thus in America in 1918 cases of typhoid were undoubtedly included among the hordes of sufferers from pandemic influenza. Such difficulties make it by no means easy to assess the extent to which wars are responsible for any particular infections. It can, however, be taken as certain that the character of the diseases associated with war has gradually changed. Thus typhus fever, after Frascatori's clear description, can be traced through a long succession of wars. During the Thirty Years' War (1618-48), in which most of Europe became involved, it accompanied the armies in the East; it was prevalent during the War of the Polish Succession (1733-5) and again in the Seven Years' War (1756-63), when Austria, France, Russia, and Sweden were aligned against Prussia and England. The Napoleonic Wars were followed by the most severe epidemic in the history of Europe, while in the Crimean War (1853-6) many thousands of Russians died of typhus. It again played havoc in the Russo-Turkish War of 1877-8. Thereafter typhus and war parted company till 1914-18, when the disease was rampant in Serbia, Poland, and Russia, though in both the German and Allied armies the incidence was negligible. So far in the present war only small outbreaks of typhus have been reported—in Poland, Mecklenburg, Albania, and Spain. Small-pox was a menace for the last time in the Franco-Prussian War of 1870, typhoid in the Russo-Japanese War of 1904. Bubonic plague has not played a major part among war pestilences since the Russo-Turkish War of 1827-9. Plague

¹ *F.A.M. Rev.*, Wash., 1941, 55, 547.

would seem to follow the trade routes rather than the army. Cholera also became negligible after the German-Austrian War of 1866, when about 100,000 persons died of the disease.

Dysentery and malaria, however, are two diseases which still occasion a considerable morbidity if not mortality among troops in wartime. Dysentery was especially prevalent in the Thirty Years' War and in the Crimean and Franco-Prussian campaigns. In the Sino-Japanese War of 1894 it was responsible for 38,000 deaths. There is no need to recall its frequency at the Dardanelles, while in the German Army on the Eastern Front it was one of the most important causes of illness, with more than 155,000 cases and a fatality rate of about 12%. Malaria was prevalent in East Africa, Palestine, Southern Italy, and Salonika during 1914-18, but its incidence was as nothing compared with the American Civil War, when over half the troops contracted the disease. In East Africa, however, among 50,000 men there were more than 72,000 admissions of malaria to hospital. Yellow fever has not played an important part in any major campaign, but it is well to remember that in Santo Domingo, the modern Haiti, it successively annihilated a British and a French army in 1794 and in 1801, leaving the immune negroes in possession of an independent republic.

During the war of 1914-18, when in both the Allied and the German armies more deaths were due to wounds than to disease, the influenza pandemic overshadowed all other infections, causing in the whole world some 21½ million deaths. In the British Army, apart from acute diseases of the respiratory system, tuberculosis either attributable to or aggravated by conditions of service was responsible for the invaliding of 35,000 men; and in the French Army, among 8,400,000 men mobilized, 110,000 were discharged with tuberculosis. There was a considerable increase of venereal diseases among all the armies. In the U.S. Army the largest number of primary admissions were due to influenza, venereal disease, mumps, and measles: the leading causes of death were influenza, tuberculosis, measles, and cerebrospinal meningitis. Measles, with 2,370 deaths, was especially prevalent in training camps. The aftermath of the war of 1914-18 showed its worst effects in Russia and Poland, when from 1919 to 1921 millions suffered from typhus, typhoid, dysentery, relapsing fever, and cholera, a condition of affairs which almost beggars description.

During the present world war there has as yet been little to record among the warring nations beyond mild influenza, German measles, and cerebrospinal meningitis, which was already showing an upward trend in 1937 and 1938. In England the shelters have so far not been responsible for any epidemic. In June and July, 1940, there was, however, a very distinct rise in the notification of typhoid fever. This rise was almost certainly due to paratyphoid, but it is only within recent weeks that at long last the weekly returns of the Registrar-General for England and Wales have recorded typhoid and paratyphoid separately. In the regular Army prophylaxis against small-pox, typhoid, and paratyphoid, and, except in the Home Guard, against tetanus, should control these diseases; and the new chemo-

therapy is expected to reduce the hazards of gonorrhoea, cerebrospinal meningitis, and pneumonia. In the general population diphtheria and T.A.B. immunizations are being popularized, but colds, influenza, pulmonary tuberculosis, and dysentery all present problems which must be carefully investigated.

ANAESTHESIA IN CHEST SURGERY

Anaesthesia in chest surgery is difficult, and those who have to undertake it will be grateful for Dr. Nosworthy's review of the subject and for his expert elucidation of many of its problems. There are two chief groups of cases in chest surgery: the civilian sick, who seldom need emergency operations, and war casualties. Although the condition of the former can to some extent be built up before operation, they include many cases of chronic toxæmia, sometimes even with amyloid disease. A non-toxic agent is therefore necessary, and of those which will produce satisfactory anaesthesia cyclopropane is the best. Operation on some war casualties can be deferred until anti-shock measures have proved effective, but there are others—in which, for example, the chest is full of blood-clot or there is an open pneumothorax—where operation should be undertaken without delay and while anti-shock treatment is being carried on. The anaesthetist's duty in every operation is to maintain efficient respiration. This is particularly difficult to accomplish in cases in which the pleura is open. During a thoracotomy a drip blood transfusion should be in progress to maintain circulatory efficiency.

Nosworthy deals at length with the problems of an open pneumothorax. There is collapse of the lung on the affected side with movement of the mediastinum to the other side, and some compression of the sound lung as a result. When the size of the opening in the chest is small respiration may not be greatly hindered, for there is partial expansion of the deflated lung. With a wide opening, however, on expansion of the thorax during inspiration, the lung on the affected side collapses still further, air being drawn from it into the sound lung, and sputum also if this is present. During expiration the sound lung discharges partly into the collapsed lung and partly into the trachea. This is known as "paradoxical respiration," as the lung on the affected side collapses further with inspiration and expands on expiration. Even the one sound lung does not work efficiently. This condition is made much worse by a sudden fit of coughing, with its accompanying dyspnoea, and coughing may be stimulated when there is disease of the lung with secretions which pass on to a sensitive area of mucous membrane. Dyspnoea increases the ill effects of paradoxical respiration, and Nosworthy suggests the phrase "vicious circle coughing" to describe this sequence of events, which may progress to death from asphyxia. For cases with open pneumothorax he recommends that inhalational anaesthesia should be used, that this should be deep enough to abolish the cough reflex, and that respiration should be "controlled"—that is, active respiratory movements should be abolished and the anaesthetist should thereafter continue oxygenation and anaesthesia by rhythmic squeezing of the bag of the anaesthetic apparatus. "Controlled respiration" may be achieved by depressing the respiratory centre by sedative drugs and anaesthetic agents until it fails to respond to normal concentrations of CO₂; or by reducing the alveolar CO₂ by over-ventilation in a closed circuit (CO₂-absorption) apparatus; or by a combination of these two methods. Nosworthy uses the second method. Cyclopropane with

controlled respiration as described abolishes the dangers of open pneumothorax, and is an agent from which, after anaesthesia, patients recover quickly and soon regain the cough reflex. In discussing spinal anaesthesia Nosworthy points out that as the cough reflex is not here abolished "vicious circle coughing" may be established. Other agents in regular use are discussed, and the cases in which local anaesthesia is satisfactory are mentioned. Nitrous oxide is not favoured because of the low oxygen percentage with which this form of anaesthesia is associated. The use of tracheo-bronchial suction for the removal of excessive sputum is discussed. Nosworthy's important paper ends with a valuable section on chest casualties in war.

MASS RADIOGRAPHY AND EARLY PULMONARY TUBERCULOSIS

The technique of making a photographic reproduction of the x-ray screen on a miniature film has now been so far perfected that mass radiography of the chest is a practical possibility. The films so obtained are sufficiently detailed to show even very small lesions. Sparks,¹ after viewing over a hundred miniature films and then comparing them with the full-sized radiographs, found that when a pathological lesion existed, its presence, if not its nature, was almost always recognized in the miniature film. Galbraith² has by this method examined over 100,000 recruits for the Australian Army; as a result 2.7% of these were suspected of having some abnormality and were referred for examination by a full-sized radiograph. It was found that one man in every 200 (0.56%) had active pulmonary tuberculosis. This figure compares closely with those of other workers. Dudley and Fitzpatrick³ reported that mass radiography of over 18,000 men of the Royal Navy showed a somewhat lower incidence (0.24%) of active tuberculous lesions, while Ellman⁴ found 0.83% of active lesions in 601 recruits. S. H. Graham and M. Davies⁵ found that of 1,869 recruits referred by medical boards in Wales, 112 (6%) had active tuberculosis: the lesion was pulmonary in 108 (5.7% of all those referred). Full-size radiographs were taken. The authors stress the value of miniature radiography and the importance of examining contacts. Heaf⁶ has pointed out that mass radiography should not be used merely as a means of determining the incidence of tuberculosis, but rather as an instrument for combating the spread of infection by revealing the hidden active cases among the apparently healthy population. This would necessitate the presentation of the method to the public as part of a general fitness campaign, unassociated with any stigma of tuberculosis, and also the provision of adequate relief for those found to be suffering from the disease and for their families. Heaf suggests that there should be facilities for the investigation of suspects without removing them from their work, and that a national rehabilitation board should be established to investigate and control the domiciliary conditions, training, and employment of the tuberculous. Some such scheme is essential before any progress can be made in eradicating the disease. That it is a practical proposition has been shown by Dublin,⁷ who described a similar scheme in operation among the employees of a large American insurance company. The present system of patching up the tuberculous subject and then allowing him to return to unsuitable work, so that he only breaks down again and infects his family and colleagues, is both inefficient and expensive.

It is a truism that the treatment of pulmonary tuberculosis would be simplified if the disease could be recognized in its early stages. This object is now to some extent being achieved, for modern radiological technique, applied to large groups of apparently healthy persons such as tuberculous contacts and recruits, is producing a steady stream of patients with very early lesions and often with no symptoms. As Graham and Davies make clear, the indications for reference of cases for diagnosis should be comprehensive. Kayne⁸ in a recent article shows that the very early lesion presents many problems which are by no means solved. His use of the term "bronchogenic" applied to the isolated pulmonary focus will not meet with universal approval, as the origin of such a lesion is still obscure and may well be haematogenous (Chien-Liang Hsu,⁹ Terplan¹⁰). The management of the patient with an early tuberculous lesion is also a vexed question; to advise bed rest and sanatorium treatment, with or without collapse therapy, is a counsel of perfection, because for economic reasons, coupled with his feeling of well-being, the patient will rarely agree to such a course; and in many instances it is unnecessary, as the lesion will heal spontaneously. On the other hand, Heaf rightly states that periodical medical and radiological examinations may not be successful in preventing a breakdown in health; only too often a relapse occurs in the interval, however short, between such examinations. Both Heaf and Kayne agree that these measures must be combined with a reorganization of the patient's environment, the removal of sources of infection, the proper control of leisure, and the provision of suitable employment. These factors can be regulated only by a sound programme of rehabilitation, and thus the solution of the problem of early tuberculosis brings us once again to the importance of planning such a programme in the control of this disease.

LYMPHOCYTIC CHORIOMENINGITIS AS AN "INFLUENZAL" SYNDROME

Since the virus of lymphocytic choriomeningitis was first described in America in 1934 by Armstrong and Lillie¹¹ its existence has been demonstrated in England (Findlay, Alcock, and Stern¹²), France (Lépine and Sautter¹³), and Japan (Kasakura *et al.*¹⁴); the disease may thus be regarded as world-wide in its distribution. As a rule the nervous symptoms are comparatively benign, but on occasion they may be severe and neurological sequelae may be present. Both in America and in England evidence has accumulated to show that infection in both animals and man may occur in the absence of all symptoms. In mice, Traub¹⁵ and more recently Haas¹⁶ have shown that inapparent infection may be passaged *in utero* from the mother to her young. In dogs infection is also symptomless, but the virus may apparently be harboured for considerable periods in the spleen (Daldorf,¹⁷ and Findlay *et al.*¹⁸). In man the disease may be characterized by mild influenzal symptoms. Thus of nearly 2,000 sera from persons living in various parts of the United States of America no less than 11% showed protective immune bodies against lymphocytic choriomeningitis virus, the majority of those with positive serology no history of any involvement of the central nervous system (Wooley, Armstrong, and Onstott¹⁹). This is in conformity with the results obtained by Lépine, Mollaret, and

Kreis²⁰ from the inoculation of human beings with emulsions of infected mouse brain. In about half the cases there was no meningeal involvement, fever and malaise of an influenzal type being the only symptoms. In one instance the influenzal picture was completed by slight bronchitis and cough with mucopurulent expectoration, probably due to changes in the lungs similar to those found in guinea-pigs inoculated with the lymphocytic choriomeningitis virus. Recently Armstrong and Hornibrook²¹ have succeeded in isolating the virus from a spontaneous case in which there were no nervous symptoms of any sort. The patient was a laboratory worker who developed fever, malaise, backache, and prostration, with a leucocyte count of 2,900 cells per c.mm., the differential count showing only 45.3% of polymorphonuclear leucocytes. From blood removed on the fifth day of illness the virus of lymphocytic choriomeningitis was recovered, and the patient subsequently developed immune bodies to it.

When in 1933 Wilson Smith, Andrewes, and Laidlaw²² isolated a virus from the nasal washings of patients with clinical influenza it was hoped that the problem of the aetiology of influenza had been finally solved. Further investigation, however, showed that from many outbreaks of clinical influenza no virus could be obtained, and it was therefore suggested that the virus obtained by Wilson Smith, Andrewes, and Laidlaw should be termed "influenza virus A," while any others isolated from influenzal cases should be designated by other letters of the alphabet. Francis²³ has more recently isolated another virus from "influenza" patients which is unrelated antigenically to influenza virus A and is termed "influenza virus B." Now, lymphocytic choriomeningitis may easily be mistaken for influenza, and the same confusion has been made with Rift Valley fever virus (Francis and Magill²⁴). Mild cases of yellow fever may also be, and in fact have been, mistaken for influenza. "Influenza," in fact, is merely a clinical syndrome which may be occasioned by an ever-increasing number of different viruses. There is an obvious moral to be drawn: if a new virus is isolated by someone who is primarily interested in influenza viruses the new arrival will probably be labelled as an influenza virus; if its discovery is due to someone who is not specially concerned with influenza the virus will be given an independent name. It may be said that there is nothing in a name, but, since we are all to some extent influenced by names, confused nomenclature is only too likely to lead to confused thinking.

INCREASE IN SALARIES OF NURSES

It was evident that with the increase in the salaries of members of the Civil Nursing Reserve (*Journal*, April 12, 1937) some comparable concerted action by voluntary hospitals would be necessary to improve the rates of pay of their nursing staffs. At the same time it was obvious that voluntary hospitals were not in a position to shoulder the increased burden which higher salaries for nurses would entail. Acting on this latter view the British Hospitals Association, in co-operation with King Edward's Hospital Fund for London and the Nuffield Trust, promptly took up the matter with the Minister of Health, with the highly satisfactory outcome that increased expenditure by voluntary hospitals on nurses' salaries will rank for grant. In an explanatory memorandum to all voluntary hospitals in England and Wales the British Hospitals Association states that its council at a recent meeting decided to advise hospitals to adopt the following minimum scale of salaries:

probationers, first year £30, second year £35, third year £40, fourth year (until State Registered) £50, fourth year (State Registered) £70; State Registered staff nurses £90 per annum. A hospital will be eligible for the grant if it either adopts this scale of salaries as from August 1, 1941, or has, since April 11, 1941, increased salaries in such a way as to make these minimum rates effective. The grant will be 50% of the expenditure incurred in bringing the salaries up to this scale or, where the new scales exceed these minimum rates, up to £95 for State Registered nurses and £40, £45, and £50 for probationers in their first, second, or third year. The medical profession will welcome this long overdue improvement in the meagre pay of nurses and will congratulate the British Hospitals Association on the success which has attended its efforts to safeguard the interests of voluntary hospitals in this matter. Two gratifying features of the negotiations are that for the first time some uniformity has been secured on the initiative of a body representing all voluntary hospitals, and that the Government has recognized the British Hospitals Association as that representative body and has entrusted it with the allocation of a substantial Exchequer grant. The B.H.A. points out, in the memorandum already referred to, that the scheme is provisional pending the findings of a national committee on nursing salaries which is to be appointed by the Minister. This committee will consist of two panels representing employers and employed, and the B.H.A. has accepted the Minister's invitation to be represented on the employers' panel in association with the King Edward's Hospital Fund and the Nuffield Trust.

MINISTRY OF HEALTH AND MINISTRY OF PENSIONS

Sir John H. Hebb, C.B., C.B.E., retired at the end of August from the posts of Director-General of the Emergency Medical Service of the Ministry of Health and of Director-General of Medical Services at the Ministry of Pensions. On retirement Sir John Hebb has agreed to make his services available to the Ministry of Pensions. He will be succeeded as Director-General of the Emergency Medical Service of the Ministry of Health by Prof. F. R. Fraser, who has for some time been acting in that capacity. Sir Wilson Jameson, Chief Medical Officer of the Ministry of Health, will continue to be responsible, on the medical side, for the co-ordination of the Emergency Medical and Hospital Services with the general medical and hospital services of the Ministry.

On page 351 will be found a notice relating to the publication of a Fourth Addendum to the *British Pharmacopoeia*, 1932. We are asked by the Pharmacopoeia Commission to draw special attention to the paragraph stating that no additional monograph or emendation of a monograph is official until the new Addendum has appeared.

We regret to announce the death at the age of 81 of Dr. Herbert R. Spencer, consulting obstetric physician to University College Hospital and emeritus professor of obstetric medicine, University College, London. He was an old and valued friend of this *Journal*. We hope to publish a memoir next week.

A liaison committee between the British Medical Association and the British Hospitals Association is shortly to be set up. This committee, which will meet as and when required to discuss matters of mutual interest, will consist of three representatives from each Association and their respective secretaries.

MEDICAL SCHOOLS IN RAIDED AREAS PROGRAMME FOR THE NEW SESSION

For the third year the winter session of the medical schools opens under war conditions. Two years ago in London, when it was believed that air bombardment was imminent and the hospital population, actual and potential, was largely evacuated, arrangements were made for the dispersal of the students in the sectors for at least a part of their medical training. Last year it was hoped to resume more normal working, but air attack suddenly started in earnest, and among the buildings which suffered conspicuously were the large teaching hospitals. It is common ground that the task of medical education must go forward whatever happens. Present conditions cause inconvenience to staffs and students, chiefly in the matters of travelling, billeting, and splitting up into small groups, and to deans and administrators there is the constant anxiety of ensuring adequate clinical instruction out of London.

Nevertheless the volume of teaching has not been lessened nor its standards lowered. Indeed, it is surprising to what slight extent the work, judged by examination results, has been affected by the distractions of war. Difficulty has been experienced here and there, but much less than had been expected. In some respects the new framework of teaching has proved advantageous, for it has given the student a more varied clinical experience, has acquainted him with expedients of a kind which he may have frequently to employ in practice, and has brought him, in the outlying hospitals, into closer co-operation with his teacher. One dean says that the students work harder, are more closely supervised, and are much more content. The new situation has useful elements which may well remain in the post-war pattern of medical education. Is it likely that London will see again its twelve large teaching hospitals with their total of 6,100 beds entirely concentrated between London Bridge and Hyde Park Corner, Paddington and Denmark Hill? Several of the hospitals have already built country annexes, and possibly at some time the annexe may become the main hospital for in-patients and the town building merely a clearing station and out-patient department, the students distributing themselves between the one and the other.

Pre-clinical Education

The pre-clinical students of the London schools have, as a rule, gone further afield; many of them are the guests of another university. The pre-clinical school of the London Hospital remains at Cambridge with its own pre-war staff for anatomy and physiology. The St. Bartholomew's school is also at Cambridge, the students residing at and being attached to Queens' College, where they have the use of common-rooms, dining hall, and athletic facilities. The pre-clinical students of the Middlesex have gone to the University of Leeds and the Leeds Medical School, and there, by the courtesy of the Vice-Chancellor, they continue to be taught by their own professors for the London degree in medicine and the examinations of the Conjoint Board. King's College Hospital students, with their teaching staff, have been evacuated to the University of Birmingham, and the students of Westminster Hospital and of St. George's take their pre-clinical subjects with King's wherever King's happens to be. The pre-clinical students of the London (Royal Free Hospital) School of Medicine for Women continue to work in the laboratories of the University College of the South-West at Exeter; a certain number of the students are living in college halls of residence, and others are in lodgings in the city.

St. Thomas's pre-clinical studies are carried out in temporary quarters at Godalming, where huts and converted buildings have been equipped with fittings from the medical school in London, including x-ray apparatus for the teaching of anatomy. The teaching staff and technicians have all been transferred to Godalming, and, by the kind co-operation of that old foundation, pre-medical subjects are taught in the new science wing of

Charterhouse School. Guy's pre-clinical students, both medical and dental, are at Tunbridge Wells, where senior members of the pre-clinical staff and about 170 students are housed in hostels.

The Clinical Years

Only Charing Cross Medical School has been completely evacuated, though the building in Chandos Place is still being used for administrative purposes. A large property has been purchased in Hertfordshire—Chaulden House, Boxmoor—for use as a residential school with sixty students. It is arranged with dormitories, common-rooms, and classrooms, a pathological laboratory has been built, and the textbook section of the old library and many specimens from the museum have been transferred. The principal centre of clinical instruction is Ashridge Hospital (1,200 beds); other hospitals in the sector are also used. The entry of students is limited to thirty each year, and each student is assured of a large number of cases under his personal supervision during his time as clerk or dresser.

At all the other London hospitals some, if not the bulk, of the teaching is carried out in London. The "London"—which was the first of the large hospitals to be severely damaged, receiving direct hits in one night almost a year ago, and others since, not to speak of incendiaries—still maintains its medical school in the old quarters, and the 300 beds in the hospital are the main teaching centre for "London" men. Three hospitals across the London border—the E.M.S. hospital at Goodmayes, Chase Farm Hospital, Enfield, and St. Andrew's, Billericay—are also used. All students go to one of these hospitals for their first six or nine months, where they have experience of the wards under the supervision of members of the honorary staff attached to the hospital in an E.M.S. capacity. They are then transferred to the Chase Farm Hospital, where a pre-war course in pathology is held twice a year. During this same period they go each week to a fever hospital and to a mental hospital for instruction in infectious diseases and in mental disorder. They are then posted to hospitals where the necessary facilities exist for the teaching of obstetrics and gynaecology, mostly at the London Hospital's new annexe at Brentwood, where there are 348 beds. A group of senior students are at certain outlying hospitals, such as the North Middlesex, which is a large county hospital at Edmonton with normally 1,300 beds; another group act as student house officers or E.M.S. dressers at sector hospitals; and the most senior return to live either at the London Hospital itself or else at one of six large hospitals in the vicinity, where they work in the morning and go on to the "London" for systematic instruction in the afternoon. The dean, Dr. Clark-Kennedy, says that the organization of the medical school is sufficiently elastic to be adaptable to any circumstances that may arise during the coming winter, and the students are all getting valuable and varied clinical experience.

No hospital suffered more grievous wounds than St. Thomas's, but here again it carries on busily with a limited number of beds and with out-patient departments working almost normally, and its clinical students in small batches are detailed to work there as well as in the country. They all pass through an excellent period of elementary teaching at Woking, then a period at Godalming. The new-linked St. Thomas's at Hydestile, Godalming, which was opened in April of this year, permits the students to work as in-patient clerks and dressers. Parties of students are also based for three-month periods at other hospitals where members of the honorary staff of St. Thomas's are working. The teaching of midwifery is done at a maternity hospital in Woking, and the final-year subjects, systematic lectures, and revision classes are centred at Guildford, where a large school has been leased, and where the medical school library will be established, as well as a residential hostel.

More Use of Sector Hospitals

The "New Westminster," completed just before the war, was hit, but the medical school, which has happily remained intact, serves for all lectures, demonstrations, tutorial classes, and laboratory work, while the students distribute themselves between the hospital, with what clinical material remains there, and the Staines Emergency Hospital (Middlesex County Council). Until last December the school carried on with practically pre-war arrangements, although the reduction of

honorary staff and available beds was a handicap; but after the hospital was hit a new departure had to be taken. The arrangement now is that six months' clinical appointments are taken at Staines, and the rest in London, where, although the material is scanty, it still allows sufficient scope for representative education. Midwifery is being taken at Ripley, Surrey, where expectant mothers of the Westminster district have been evacuated. The number of clinical students is at its maximum—namely, 120.

St. Bartholomew's clinical students are housed in three places. The first-year batch are at Hill End, Hertfordshire, where they carry out their pre-medical courses, serve as dressers and clerks, and do their pathological work. Improvements have been made in the pathological laboratories there, and the museum has been transferred to that institution. Second-year students go back to Bart's, where they do the whole of their out-patient work (the out-patient departments are in practically full swing), and during the same period their midwifery, facilities for which have been much improved. Final-year students go to Friern Hospital, New Southgate, where they do their second period as clerks and dressers, and also gynaecology. Here better facilities for lectures have been provided and common-rooms installed.

The majority of the Middlesex students are still at the Middlesex Hospital; others are attached to Tindal House Emergency Hospital, Aylesbury, Mount Vernon Hospital, Northwood, and the Central Middlesex Hospital, Acton Lane, for clinical instruction, and the students are moved between these and the Middlesex according to the stage reached in their studies. Some are receiving instruction at the Royal Hospital, Wolverhampton (292 beds).

At Guy's the working conditions are much the same as they were a year ago. Teaching facilities have not suffered through the bombings which Guy's has taken. The first six months of the clinical period are spent in the pleasant neighbourhood of Pembury Hospital, Kent, and later years at Pembury, Farnborough, and Guy's itself, according to the special facilities offered at each centre. The dental students spend their last two years at Guy's.

Innovations which will Remain

St. Mary's is fortunate in that hospital and school have not so far been affected by the war. St. Mary's students are taught at their own hospital and at three large L.C.C. hospitals—two of them in the immediate neighbourhood—also at Harefield, a Middlesex county hospital with 1,000 beds, which represents for practical purposes a second St. Mary's in the country. The students live at all these five hospitals and work at St. Mary's at certain periods of their training. Here again the dean (Sir Charles Wilson) states that contact between students and members of honorary staff is much more intimate than in peacetime. Five of the honorary staff live at St. Mary's and a number reside quite close to Harefield, so that the students see more of their teachers than formerly. Moreover, the smaller number of students at each hospital enables them to extract the fullest possibilities from the new arrangement. This is the only innovation of moment in medical education during the war years, and in Sir Charles Wilson's opinion it has come to stay. The number of resident appointments available annually at St. Mary's before the war was thirty-one; now there are 101 resident appointments made annually at the various large hospitals in the sector. These are made by St. Mary's, and the holders work under members of the honorary staff; every man who wishes to have a resident appointment can get one. St. Mary's has for some years had a restricted entry in order to preserve the ratio between beds available and number of students; the entry in the academic year 1940-1 was sixty-eight, and the number working was approximately 430.

The St. George's students in their first year have been taught at an emergency hospital and at King Edward VII Hospital, Windsor; in their second year at the West Middlesex County Hospital, Isleworth (where there are excellent facilities for obstetrics and gynaecology), and in their final year at Hyde Park Corner. Recently, however, the tendency has been to allow the first-year men to work in the wards at St. George's, and unless there is much more severe bombing than has been lately experienced, it seems probable that most of the first-year and final-year men will do the greater part of their work there. The students of the London (Royal Free Hospital) School of Medicine for Women carry on mainly at the hospital itself and at the Three

Counties E.M.S. Hospital at Arlesey, Bedfordshire. A small number are working at other hospitals in and near London, and a few at the Royal Devon and Exeter Hospital.

Town and Country Experience

University College Hospital Medical School, which is for clinical studies only, has taken over Stanboroughs Hydro Annexe, near Watford, where it has established bacteriological laboratories, lecture room, library, and museum. Accommodation is available in the building for sixty resident students. They carry on their clinical work at Leavesden E.M.S. Hospital, close to the school, and Stanboroughs Hydro itself has been taken over as a hospital of seventy-five beds under the charge of Sir Thomas Lewis. While carrying out their medical and other appointments the students return to Gower Street for periods of three weeks, during which time they form part of the E.M.S. scheme and assist in the treatment of any air-raided casualties. Arrangements have also been made for them to attend consultative out-patient clinics held by members of the University College staff at Watford Peace Memorial Hospital.

Since last September King's College clinical men have begun their work at one of the sector hospitals, with the usual pathology course and elementary medicine and surgery classes, lasting for about three months. They are then moved for ward work to another of the sector hospitals, where they have spent the next six or nine months, returning to the first hospital to serve as dressers and clerks for their second year. The third year is spent at King's College Hospital itself, where attendance is made in the out-patient department and at the senior tutorial classes in preparation for the final examination. Midwifery cases are attended by students at three hospitals in the sector, including the one at Denmark Hill.

West London Hospital Medical School reports very little disorganization beyond diminution in teaching staff owing to members joining the Services. Teaching is continued in all departments. Entries have been smaller, but this is no disadvantage owing to the necessary curtailment of beds available. The actual turnover of patients, however, is not much less than in peacetime, as the average stay is reduced by evacuation to other hospitals. So far it has not been necessary to make use of the sector hospitals for teaching, and the entire work of the school, where forty students, the majority of them women, are taking the clinical course, goes on at Hammersmith.

The British Postgraduate Medical School, although here again the number of beds is reduced and the full-time staff to some extent depleted, is continuing its teaching on pre-war lines, with bedside tuition and lectures rather than specific courses. The teaching is of a high standard, suitable both for those who wish to refresh their knowledge and for candidates for higher examinations. Special courses on war medicine and surgery and other subjects have been held in alternate weeks. These intensive courses, lasting a week and suitable for officers in the Services, are advertised in advance in the medical journals. It is proposed, if circumstances permit, to start the special course for the London University diploma in clinical pathology in October.

Provincial and Scottish Schools

Provincial medical schools in areas which have suffered from air raids have been much less disturbed. At Bristol, for example, there is no change in the general arrangements, and adequate provision is made for both clinical and pre-clinical students. At Birmingham the school is full to capacity, and many applications are having to be refused; this is probably due to the difficulties of some of the medical schools in London in taking their normal numbers. The University of Durham is carrying out its clinical studies at hospitals in Newcastle-upon-Tyne, and in the medical school there the pre-clinical students are being taught as usual. All the students remain at hospitals in the city. Even the maternity hospital, where obstetrics is taught, although it has been transferred to temporary premises, is still within the city boundary. The same is true of the Scottish schools. Glasgow has been raided, but there have been no changes in the disposition of the students or arrangements of courses, and the routine of the medical faculty has not been interrupted.

At Liverpool the arrangements are almost normal, apart from minor adjustments of the time-table and the transfer of clinical

clerks and dressers from hospitals which have been seriously damaged to those which have not. Classes for both pre-clinical and clinical students continue to be held at the university and its teaching hospitals. At Manchester the usual curriculum is being followed; fees, scholarships, and resident appointments are the same. Owing to the depleted wards in the Royal Infirmary arrangements have been made for teaching to be given at the E.M.S. Hospital at Baguley, a short distance from Manchester, and teaching is also being given at other voluntary and E.M.S. hospitals.

The medical course at Leeds has not so far been affected by enemy action. Here, as at other schools, several members of the staff are absent on war service, but their loss has been largely offset by the valuable help received from the emeriti. The number of students has not greatly fallen; women students now form one-quarter of the total. The past session saw the introduction of a revised curriculum, which allows students who have gained the Higher School Certificate in chemistry and either physics or botany to omit the pre-registration course in those subjects and begin at once the medical course proper, which has been extended by three months to five years and nine months.

Sheffield, in spite of heavy air raids at one period, has experienced remarkably little interference with the normal routine of the medical school. The university suffered minor damage, which was soon repaired and did not interrupt teaching. Clinical work continues at all the teaching hospitals, although the number of in-patients has been reduced. For about a month after the heavy air raids out-patient material was scanty, but the situation gradually improved. The number of in-patients is now from about one-half to three-quarters the peacetime level, but Sheffield has always prided itself on the provision of the maximum number of beds per student, and claims still to be in advance of most other schools in this respect. Maternity cases have been removed from the centre of the city, but there is ample living accommodation for students near hospitals where this work is done.

In Cardiff the arrangements for the clinical school of the Welsh National School of Medicine have had to be somewhat altered because of raid damage to the Royal Infirmary. The infirmary now takes 150 in-patients as compared with its normal 400; other patients are received at the Whitchurch Emergency Hospital four miles away, and here are the beds of the medical and of the surgical units, for which good pathological and radiological services are arranged. A number of other beds are provided at the convalescent home of the infirmary, also four miles out. Thus the normal bed service is practically continued, and school time-tables have been altered to meet the new distribution. The school has a full complement of students (about 350). Out-patient work is done in the morning at the infirmary, and the new Pathology Institute in the infirmary grounds is partly completed and available for use for pathology teaching.

With the reservation of medical students from military service it became a particular obligation upon those responsible to see that medical education was maintained at the highest possible level. How well they have risen to the occasion, even in areas where difficulties were extreme, is evident from the foregoing account.

Special vocational training courses are shortly to be available for all disabled persons whatever the cause of their disability, although for the present they will be confined to those who appear likely, when trained, to obtain and keep employment under ordinary industrial conditions. The courses and the centres where they will be given are being arranged by the Ministry of Labour, but the Ministry of Health in a circular (No. 2449) asks hospitals in the Emergency Hospital Service to notify the nearest Employment Exchange of any patient suffering from some disability which will prevent him from following his original employment. In the case of a hospital which is an Orthopaedic Centre or Fracture Department a special form (W.D.1) should be completed and sent to the Employment Exchange which has been scheduled to serve that hospital (a list is attached to the circular); the Employment Exchange will then arrange for one of its officers to interview the patient. Form W.D.1 is in two parts: the first to be completed by the hospital and the second, a confidential document, by the medical officer.

TESTING NIGHT VISION

BY

N. BISHOP HARMAN, M.B., F.R.C.S.

In the *Journal* of April 26, 1941 (p. 636), I gave an account of a method of testing night vision, and of its assessment by definite measurement, that might be of value in judging the night vision of individuals generally. This summer the black-out has not troubled many of us. Soon we shall all once more be affected by it, so that any means of measuring the safety of individuals in such feeble light as there will be out of doors at night is worth considering.

During the summer months I have been able to test large numbers of normal healthy folk, from childhood to the seventies, with the Disk-spotting Night-vision Test (made by Theodore Hamblin, Ltd., 15, Wigmore Street, London, W.1). A total of 700 subjects have been examined and their reactions recorded.

The Disk-spotting Test

The nature of the test is easy to understand. It is a simple imitation of what we see when we look into the sky on a clear starlight night. Sir James Jeans, in an address given in March, 1941, said that the light we see from all the stars, just as with the moon, is a reflection from the sun. "The old idea of Jupiter being a boiling mass has been destroyed, for it has been established that the total radiation of the planets was always equal to the radiation received from the sun." In the disk-spotting test the "sun" is a standard candle burning 120 grains in an hour: this is shielded in a box arranged so that a beam of light radiates in one direction only. The "stars" of the test are white disks mounted on black velvet. Each disk measures half an inch in diameter, and is separated from other disks by an eighth of an inch. The disks are grouped in similar patterns, but the number in each group varies. That these groups of white disks look somewhat like stars was evident when a small boy came into a room where a number of them were hanging on a screen and asked: "What are those stars for?" The distinction of these disks in good daylight is notable. Normal-sighted subjects can count them at 25 metres and more. One young man counted them at 50 metres. There are four groups of disks numbering from four to seven, and since the baseboard can be hung from any corner there are sixteen possible variations. In the night-vision test the disks are hung at a distance of 5 metres from the candle-box. Both are on the same level. The room in which these tests are carried out is totally dark, except for the candle beam and the reflected light from the disks. The subject is required to count the number of disks in the group shown in the candle rays. He begins at a distance of 5 metres from the test and moves either backwards or forwards according to his reaction.

The Illumination.—The reflected light that reaches the eyes in this test is very small; at 3 m. it measures $1/688$ foot-candle; at 4 m. = $1/871$; 5 m. = $1/1075$; 6 m. = $1/1302$; 7 m. = $1/1550$; 8 m. = $1/1816$. Since reflection from a white surface is 84% of the incident light, the glow of the disks at 8 m. is less than $1/2,000$ f.c. Moonlight is $1/50$ f.c. When one comes out of the daylight into the darkened room the candle beam and the lighted white disks are quite invisible. In making the tests on military drivers the contrast between indoors and outdoors was most striking. These tests were made in a Nissen hut some 10 metres long, in a coppice of thin brushwood. Stepping from the brilliant sunshine out of doors into the darkness of the hut was an almost painful experience. One was quite blind. But more disturbing was the whitish glare that filled the central part of one's field of vision. Slowly this glare faded, and then one could see the candle beam. Fifteen minutes was ample time for this recovery. Every subject had fifteen minutes in the dark before being submitted to the test.

Routine in Making the Test.—The subjects were brought into the dark room in groups of a score. The test was explained to them. They were told that the white blobs they would see in the candle glow were made up of sixpences which they were to count.

For testing large numbers there are certain conveniences: (1) a double room—one for collecting subjects, the other for the test; (2) two capable helpers—one, in black clothes and black gloves, to alter the position and number of the disks constantly, and one to register the results on the prepared charts. Each subject was allowed six trials. Since they saw, or heard, each other's test there was keen interest in the results. Some schoolboys who did poorly asked for a second trial. They were given this, but their reactions did not vary.

A colleague put this question to me: Would it be possible to judge the number of disks in a group by estimating the size or area of the white patch? The answer is, Yes and no. To a new subject there is no knowledge of the difference of size in the groups from four to seven. But to one who has been watching hundreds of reactions, as I have, it is possible to judge the numbers when the difference is considerable—e.g., I can distinguish four and seven beyond my proper distance, but six and seven I cannot separate by size. Counting is necessary for a correct reaction.

Age Groups of Subjects Examined

The subjects were divided into three age groups: Group I from 10 to 18; Group II from 19 to 40; and Group III 41 and over.

Group I.—By the courtesy of Dr. J. Ferguson, medical officer of health for Surrey, I was allowed to examine all the children in a first-class country secondary school. The children were well bred and well kept, and they were expected to give a standard reaction to the test for night vision. They numbered 210.

Group II.—By favour of Colonel E. A. McCusker, M.C., R.C.A.M.C., A.D.M.S. of a Canadian Division, I was permitted to examine large numbers of troops. In civil life Colonel McCusker was an ophthalmic surgeon at Regina, Canada, so his help in arranging for this test was of particular value. These men were a fine class for the test. Their ages ranged from 19 to a little over 40. They were all of first-class physique, and with their full Army rations and outdoor life they were expected to give an excellent night-vision reaction: 427 of these men were examined, 177 of them being drivers of tanks, trucks, and lorries. This group was subdivided into those aged from 19 to 30 (Group IIa) and those from 31 to 40 (Group IIb), the men over 40 being included in Group III.

Group III.—Dr. J. R. Bentley, medical officer of health for Godstone Rural District Council, kindly gathered a number of residents for testing. These and the "over forties" of the Canadian troops numbered 51.

Selecting the Subjects

To get something like standard returns of night vision a standard daylight vision is needed; therefore all subjects had their day vision tested. The day test was made by the use of a modification of my rotary E test. On a two-inch card a letter E (of the size that should be seen at 5 metres) is set on each of the four sides with the "fingers" of the E pointing up, down, right, or left. The card is pivoted on a baseboard, so that it can be rotated freely. It is shifted for each subject. The subject toed the line at 5 metres, with both eyes open. If he gave the correct position of the letters he went on to the black-out room. The test is speedy. Children and soldiers stood in groups awaiting their turn; they saw what they had to do, but no one could learn the order of the letters. It is of interest to note that of the 427 Canadians all passed the test except one N.C.O. aged 43 who was engaged in office work.

Night-vision Reactions

Group I, aged 10 to 18.—The curve of the children's reactions (Fig. 1) is the best of the lot. No less than 48.5% did the test at from 5 to 6 metres. The rise of the curve to these reactions is sharp and distinctive: 29.5% had poorer reactions, but the number of bad ones was small. The reactions were recorded separately both for age and for sex: there was no material distinction for either, except that the very high reactions, at 7.5 and 8 metres, were made only by boys—four each. Six girls did the test at 6.5 metres and four at 7 metres, but none got beyond that. These high results were checked several times.

Group IIa, aged 19 to 30.—In this most important group there were 301 subjects. Their curve (Fig. 2) shows a sharp peak at

5 metres. This peak is slightly lower than that of Group I. The main mass (66%) ranged from 4 to 6 metres, and 22% had poorer reactions. The high reactions, from 6.5 to 8 metres, totalled 12.6%. The actual numbers of these high reactions are more distinctive: twenty-three reached to 6.5 metres; thirteen to 7 metres; four to 7.5 metres, and one to 8 metres. These high reactions were not quite so numerous as in Group I.

Fig. 1.—Group I.

Fig. 2.—Group IIa.

Group IIb, aged 31 to 40.—The curve of this group (Fig. 3) also has its peak at 5 metres, but the mass are more inclined to the lower reactions. No less than 36% reached only 3 to 4 metres. On the high-reaction side the numbers are smaller. Reactions at 6.5 to 7 metres totalled only 4%; and no one reached the highest reaction of 8 metres.

Group III, aged 41 and over.—Of these, 70% were in the forties, but despite their nearness in age to the vigorous adolescents their returns show a distinctly poorer reaction (Fig. 4). An even

space on the chart had to be made for reactions under 2 metres. The peak in this group is at 4 and 4.5 metres. Their loss of night vision is most distinctly shown when the figures of better reactions than the average of 5 metres are compared. In Group I no less than 47% did better than 5 metres, whereas in Group III only 18% did better than 5 metres. The decline in night vision with age is the natural effect of the increasing density of the crystalline lenses and the contraction of the pupils. Something

Fig. 3.—Group IIB.

Fig. 4.—Group III.

of the same effect is shown by those of all ages who wear distance spectacles; glass cuts off some light. There were two good cases in this group: a local man who reached 7 metres and a Canadian soldier 7.5 metres. The latter was aged 43 and had exceptionally keen sight.

General Reactions

Certain general reactions were noted in the responses to the test. Those who had a poor reaction showed every sign of trying

hard to see. They craned their heads, bent forwards, moved slightly from side to side, and were only too willing to step closer to the test; whereas those with high reactions—6 metres and more—stood upright and gave their answers quickly and smartly, as though the test was quite easy. Of the soldiers the 14 with the highest reactions were re-examined a week after their first test. A few did slightly better on the second test and some slightly worse. It was found that the latter had just come off night duty; so fatigue accounted for their slight decline. Of these 14 half had blue or grey eyes and half brown; one was colour-blind.

Brewer's *Dictionary of Phrase and Fable* records the term: "Cat-eyed—able to see in the dark." This may well describe those who, in the night-vision test, could see at from 6.5 to 7.5 metres and certainly the few who could see at 8 metres. The Canadian N.C.O. who entered up the records sat outside in the light. He said he noticed that the men with the highest figures seemed most blinded by the light when they came out of the dark-room, while those with low figures did not appear to be bothered. This is a confirmation of the keen sense of light in those with a high reaction. The most astonishing finding in these reactions is the wide variations in the ability of normal-eyed healthy persons of all ages to see in the dark: from 1.5 m. to 8 m.

In my earlier paper I wrote: "I find a fair average for normal-sighted persons is 5 metres. Those with 4-metres range should be safe at night. Those with 3-metres range or less had better stay indoors." These later returns confirm that opinion. I added: "Night-flying men should have a range of at least 6 metres." The later test shows that a much higher range may be attained by many young men, so that the standard for night flyers may be 7 metres or more.

Summary

A large number of normal-eyed subjects of all ages have been given a severe night-vision test which requires ability to count small white disks in a minimum candle-light at a maximum distance. The results show that the average person can count these small disks in light of only 1/1075 candle-power at a distance of 5 metres. They also show that there are some folk with exceptionally keen night vision: some young persons can pass the test even up to 8 metres distance in a light of only 1/1816 candle-power. Safety in the dark demands a fair reaction to this test and ability to see the disks at not less than 4 metres. The extended trial of the disk-spotting test shows that it can be of use in testing large numbers of people with comparative ease and with exactness.

Nova et Vetera

NAPOLEON'S DERMATOSIS

Did Napoleon suffer from scabies? This question has been debated by Napoleonic students at great length but has never been satisfactorily settled. Perhaps the chief reason for the persistence of uncertainty about this interesting point in the great man's medical history is the fact that it was not until several years after his death that, owing to the efforts of Renucci, the parasitic nature of scabies was finally accepted and the itch mite, or the *Acarus scabiei*, was recognized as the one cause of the disease. Two undoubted facts stand out in regard to the skin disease from which Napoleon certainly suffered during his third and fourth decades: one that it was an eruption attended with severe attacks of pruritus, and the other that scabies was rife in the armies of revolutionary France. The legend is that during a critical action at the siege of Toulon Napoleon seized a ramrod from the hand of a dead gunner, used it himself, and from it contracted scabies, which afflicted him for many years until finally cured by the celebrated Corvisart. Among the countless memoirs and biographies of Napoleon there are numerous references to his skin complaint, and it is suggested that his favourite pose with

one hand inside his waistcoat is due to his delight in putting it there to scratch! Dr. R. Friedman, who has contributed much to the history of scabies, has written a most interesting brochure on Napoleon's dermatosis¹ in which he sums up critically the evidence of contemporary writers (no light task!), and comes to the conclusion that the correct diagnosis should really have been dermatitis herpetiformis, a disease first described by the American dermatologist Duhring in 1885.

Dr. Friedman's thesis naturally falls into two parts: (a) the argument that Napoleon did not suffer from scabies; (b) his suggestion of the alternative diagnosis here given. Perhaps the strongest reason for supposing that Napoleon did not have scabies is the absence of any suggestion that Josephine ever caught it from him. But the siege of Toulon took place in 1793, while his intimacy with Josephine (which preceded his marriage with her by a few months) did not begin till 1796. During three years there was ample time for scabies to be cured, and it is known that Napoleon took sulphur-baths for his complaint. There is no need to dispute the fact that he certainly suffered from some skin eruption of an irritating nature for a long time afterwards; this may have been an eczematous dermatitis set up by the sulphur treatment, or possibly dermatitis herpetiformis as suggested by Dr. Friedman. We shall never know now. Corvisart was called in to treat Napoleon not before 1800, perhaps as late as 1803. Josephine summoned him, primarily on account of cough and pain in the right side (which he was lucky enough to cure with the application of two vesicants); for the skin eruption he prescribed a lotion containing *sabadilla* powder—derived from the seeds of *Schoenocaulon officinale*—which contains certain alkaloids but is devoid of anti-parasitic properties. It could not have cured scabies, and, moreover, it seems that the so-called cure could not have been permanent, for there are many allusions to Napoleon's habit of scratching himself long afterwards. Antommarchi describes his pruritic crises at St. Helena and refers to the scars which were left on his skin. These scars are certainly a point in favour of the diagnosis of dermatitis herpetiformis.

Dr. Friedman has written a fascinating little book which will amuse and interest all students of medical history.

ANCIENT BURIAL RITES AND MODERN CURRENCY

At a meeting of the Manchester Medical Society Prof. F. WOOD JONES, F.R.S., gave an address entitled "Mana and Money."

He described the finding of red patterns on the uppermost bones in predynastic Egyptian burials due to haematite used to impregnate textiles, the similar use of red ochre in Australia in native burials, and of the vegetable bright red dye from *Morinda citrifolia* employed in Honolulu. This widespread custom of associating redness with funerary observance dates back into the palaeolithic period, and the "Red Lady of Paviland" is one of the best-known British examples.

Red Pigments, Cowries, Gold

Throughout the world the importance of red in burials was almost universal, and is seen to-day among the remnants of humanity still living in a palaeolithic stage of culture. If mineral or vegetable dyes were not available, then red coral or other substances were employed. Associated with the use of red pigments in predynastic Nubian burials other apparently irrelevant objects were found. Thus, cowrie shells or imitations made from hard black porphyry were present, and can also be found in graves in other parts of the world, often hundreds of miles from the tropical seas where the cowrie shells are found. These cowries are considered as necessary adjuncts in the preparation of the corpse for burial. In lands far from

the sea imitation cowries may be made of clay, stone, ivory, shell, or wood, and painted, glazed, or gilded. Some may be fashioned from gold. Gold in small pieces, lumps, or articles, fashioned by the craftsman has always been buried with the dead the world over when obtainable.

Prof. Wood Jones said that the reason for placing in the grave with the body (a) something red, (b) a cowrie, and (c) gold is to be found in an understanding of the symbolism embraced in sympathetic magic. Red, which is a rare colour in nature, symbolizes fire (the source of heat) and the redness of the life blood; it is also associated with the setting sun (and the rising sun as it is reborn in the morning). Thus redness was the earliest rebirth symbol. The cowrie, resembling the female pudenda, is likewise a charm to ensure rebirth. Gold is incorruptible, does not tarnish, cannot be made by man, and a lump of native gold in the hand has a remarkable quality of feeling almost alive. Gold is the symbol of life and rebirth owing to its redness; it has always been the symbol of the sun and of life.

The Quality of Mana

These three things—redness, cowries, gold—have strong *mana* (or *kunta* in Australia) with the dead. The quality of *mana* or *kunta* implies "potency" or "value" (as distinct from the degraded meaning of price); thus red things, cowries, and gold are valuable (strong *mana*) to primitive people because they are potent symbols of life and its renewal after death. Objects possessing *mana* have also become good luck symbols. Thus red is lucky for the bride and red garments the luck symbol of honoured old age. The cowrie as a good luck symbol is very widespread and worn by peoples in many lands, on breast-plate ornaments of horses in Europe, on idols in New Guinea. The good luck symbolism of gold is universal (e.g., the golden wedding ring). Further, these *mana* objects by extension have become symbols of royalty (royal purple, red carpets, etc.), white cowries are worn only by chiefs (as in the Friendly Islands, etc.), while gold is everywhere associated with it (golden crowns, thrones, sceptres, etc.).

Gold as Money

Finally, there is the debasement of all objects invested by *mana* as vehicles of currency. This follows their perpetual removal from circulation by burial with the body, thus maintaining a standard of rarity, which leads to their becoming the media of exchange and ultimately the currency of primitive commerce. Thus three phases of definite currency standards have existed—(1) redness (e.g., the barter value of red ochre among Australian natives), (2) cowries (e.g., in New Guinea) or shell (Pacific Islands), and (3) gold. Probably alluvial gold was used first as a standard of currency, but the first attempt to standardize it was the official stamping of lumps of gold by the Kings of Lydia (700-545 B.C.) conducted at Sardis in Smyrna, which was at the end of the great caravan route from the Far Orient. From this gold gradually derived its name of money, and ultimately only the Aztecs and the Chinese preserved their aesthetic appreciation of gold and escaped the snare of degrading its value to that of a medium of currency.

Thus (said Prof. Wood Jones) the story of *mana* and money is curious: the hoarding of red ochre by the Australian native, of red feathers or of cowries or *Tridacna* money by the Pacific Islander, gives rank and privileges to individuals and to classes in various parts of the world. Will future generations look back on us likewise as deluded savages, immobilizing our one god, gold, and prepared to sacrifice thousands of lives for its possession? Is the preservation of privilege by the possession of gold in any way more worthy than the preservation of privilege derived from the possession of cowrie shells or red ochre?

The *Journal of the American Medical Association* records that books on medicine published in 1939 amounted to 1,868,592 volumes, according to the biennial census of manufactures conducted by the United States Bureau of the Census. The biggest year was 1937, when 3,923,532 volumes were published. The total number of all books published in 1939 was 180,142,492.

BRITISH PHARMACOPOEIA, 1932 PUBLICATION OF A FOURTH ADDENDUM

The General Medical Council will publish shortly a Fourth Addendum to the *British Pharmacopoeia*, 1932, in which certain new monographs and certain modifications of existing monographs will be included. Under normal conditions, when a new *Pharmacopoeia* or an Addendum to a *Pharmacopoeia* has been ready for publication it has been customary to give facilities for advance copies to be inspected, during the three months immediately preceding publication, by medical practitioners, pharmacists, analysts, manufacturers, and others who may be interested. The Fourth Addendum to the *British Pharmacopoeia*, 1932, like the Second and Third Addenda, has been prepared to deal with conditions arising from the present emergency, and it is expedient that it should be published, and thus made official, without delay. It is not possible, therefore, to provide for the preliminary inspection of the completed Addendum, but arrangements have been made for a limited number of advance proofs to be available for supply, on application, to manufacturers of the preparations described therein.

New and Amended Monographs

The following new monographs will be included:

Acidum Mandelicum	Morphinae Sulphas
Acidum Nicotinicum	Pamaquum
Benzyls Benzoas	Paraffinum Liquidum Leve
Bismuthi Subgallas	Phenylhydrargyri Nitrates
Digoxinum	Proflavinae Sulphas
Ephedrina	Sodii Metabisulphus
Injectio Calcii Gluconatis	Sodii Morrhuas
Injectio Nikethamidi	Sodii Sulphas Exsiccatus
Injectio Procainae et Adrenalinæ	Sulphanilamidum
Injectio Quininae et Urethani	Suraminum
Injectio Sodii Morrhuas	Unguentum Hamamelidis
Liquor Sodii Hydroxidi	Unguentum Hydrargyri Dilutum
Magnesium Trisilicas	Urethanum

The Addendum will contain, in addition, certain monographs, or amendments to monographs of the *British Pharmacopoeia*, 1932, which became official by virtue of notices in the London, Edinburgh, Belfast, and Dublin *Gazettes* of February 28, 1941.

Sodii Lactas	Oxymel Scillae
Urginea	Scilla
Valeriana Indica	Tinctura Scillae
Acetum Scillae	Tinctura Valerianae Ammoniatæ
Cataplasma Kaolini	Valeriana
Mepacrinae Hydrochloridum	

and emendations to the following monographs, which will become official on the date of publication of the Fourth Addendum:

Aquæ Aromaticæ	Injectio Bismuthi Oxylchloridi
Aqua Anethi Concentrata	Injectio Bismuthi Salicylatis
Aqua Camphoræ	Injectio Ferri
Aqua Chloroformi	Injectio Hydrargyri
Aqua Cinnamomi Concentrata	Injectio Hydrargyri Subchloridi
Aqua Menthae Piperitæ Concentrata	Injectio Mersalyl
Elixir Cascaræ Sagradae	Liquor Sodae Chlorinatae
Ephedrinae Hydrochloridum	Chirurgicæ
Glycerinum Acidi Tannici	Liquor Sodii Chloridi Physiologicus
Glycerinum Aluminis	Mel Boracis
Infusum Aurantii Recens	Menthol
Infusum Buchu Recens	Mistura Magnesium Hydroxidi
Infusum Calumbæ Recens	Mistura Sennæ Composita
Infusum Caryophylli Recens	Oleum Hippoglossi
Infusum Digitalis Recens	Syrupus Pruni Serotinae
Infusum Gentianæ Compositum Recens	Tinctura Cardamomi Composita
Infusum Quassia Recens	Tinctura Ipecacuanhæ
Infusum Senegae Recens	Tinctura Rhei Composita
Infusum Sennæ Recens	Unguentum Acidi Tannici
Injectio Bismuthi	Unguentum Hydrargyri

Revised Appendices relevant to the monographs named above will be included.

It must be understood that no additional monograph or emendation of a monograph is official until the Fourth Addendum has been published.

Manufacturers interested in the production of the articles named above are invited to apply to the Secretary, British Pharmacopoeia Commission, University College Hospital Medical School, University Street, London, W.C.1, for advance copies of the monographs.

Reports of Societies

ORTHOPAEDIC MISCELLANY

The summer meeting of the British Orthopaedic Association, under the presidency of Prof. T. P. McMurray, was held at the Robert Jones and Agnes Hunt Orthopaedic Hospital, Oswestry, on August 9. A large number of members attended, and among the guests were representatives of the American Hospital in Britain. The scientific programme consisted of a clinical demonstration and the presentation of several short papers, of which the following is a summary:

Slipped Upper Femoral Epiphysis.—Mr. N. W. NISBET (Oswestry) reported that in a twelve-year period at the Robert Jones and Agnes Hunt Hospital twenty-six patients suffering from epiphysiolysis had been treated by traction. There had been a long period of symptoms of a fleeting nature before medical advice was sought, and radiographs in two planes always revealed a greater or lesser amount of displacement. He found that traction did not change the position in those cases with mild displacement, but sometimes produced considerable, although not complete, correction in those in which displacement was severe. Prolonged heavy traction appeared to have an adverse effect on the hip- and knee-joints, and in this series seemed to have some responsibility for the development of arthritis in the hip-joint. Mr. Nisbet concluded that: (1) When displacement was slight no effort should be made to correct it; the hip should be protected and weight-bearing avoided until the epiphysis had fused. In this way normal function could be achieved. Perhaps the insertion of a Smith-Petersen nail would hasten recovery, provided it did not damage the blood supply of the capital epiphysis. (2) When displacement was pronounced and not of long duration sufficient correction might be achieved by cautiously applied traction to ensure a very satisfactory, although not perfect, result. (3) If severe displacement could not be corrected by traction or was of long duration the best results followed a subtrochanteric osteotomy to correct deformity, and this treatment was much to be preferred to persistent and vigorous traction.

Pseudo-fracture of the Tibia.—Mr. N. L. CAPENER (Exeter) described the case of a child aged 7 who had complained for a month or so of discomfort about the ankle. Radiographs at that time were negative. Three weeks later a further x-ray examination showed a crack in the lower diaphysis of the tibia with subperiosteal new bone formation, appearances strongly suggestive of a "fatigue" fracture. Recovery was uneventful.

Operative Treatment of Intra-articular Fracture of Upper End of Tibia.—Discussing this subject, Mr. CAPENER maintained that because of the soft texture of the cancellous bone in this region bone pegs and screws were mechanically inefficient. He showed radiographs of three patients treated by wire applied circumferentially around the upper end of the tibia through two incisions, while longitudinal skeletal traction was applied. Early active movements were initiated and the functional and anatomical results were most gratifying.

Arthrography in Congenital Dislocation of the Hip.—Mr. RONALD FURLONG (London) showed radiographs of a series of congenitally dislocated hips in which a contrast medium (perabrodil in pure solution) had been injected within the capsule before and after reduction of the dislocation. Among many stimulating observations Mr. Furlong indicated what valuable information could be gained about the possibilities of a successful manipulative reduction, the accuracy of reduction, and the development of an adequate acetabular roof.

Treatment of Fractures of Olecranon by Excision of Detached Fragment.—Mr. D. WADSWORTH (Stoke) presented a careful analysis (illustrated by radiographs and a cinematograph) of forty patients treated for fracture of the olecranon. Twenty patients treated by excision of the detached fragment and efficient repair of the extensor apparatus were compared with twenty treated by other methods (chiefly by suture). Excision resulted in a powerful, fully mobile, and stable elbow capable of withstanding the heaviest strain in a shorter time than could

be achieved by other methods. Mr. Wainwright considered excision to be the treatment of choice in all patients approaching middle age, whatever the size of the proximal fragment, provided the coronoid process and the head of the radius were intact.

ENGLAND AND WALES

A Scheme of Training for Nurses

The Manchester Public Health Department has issued a memorandum of proposals for a State scheme of training for nurses, which has been prepared by Miss J. M. Calder, secretary to the local emergency committee for the nursing profession, at the request of Dr. Veitch Clark, medical officer of health for Manchester. Briefly the memorandum, which is very detailed and is intended to form a basis for discussion, proposes a four-years training course, the first part or basic course covering three years, and the second part or specialized course lasting one year, full registration being granted only to those candidates who complete both parts successfully. The scheme is built up on a regional plan of Central Schools of Nursing established in co-operation with the local hospitals and public health services. Each school of nursing would be part of a "Faculty of Nursing" in the University, and this faculty would arrange, with the approval of a "fully representative" General Nursing Council, the curricula for the courses, and would be the examining body. A very full syllabus for all four years is given, beginning with six months in the preliminary training school and ending with eight months' specialization in one of the following: clinical nursing, midwifery, domiciliary nursing, health visiting (including tuberculosis and school nursing), and industrial nursing. The transfer from classroom to the wards, the memorandum states, should be gradual, beginning with two hours daily in the first week, increasing to an eight-hour day inclusive of lectures and study. The memorandum concludes by stating that, on the basis of a recommendation in the interim report of the Interdepartmental Committee on Nursing, "it may be presumed that the recognition of nursing as an essential national service will secure an allocation of State funds for schools of nursing approved as training institutions for student nurses."

The *Nursing Mirror* of August 23 publishes a fully worked out scheme for the reconstruction of the nursing profession, and a reprint in the form of a folder leaflet has been received from the office, Dorset House, Stamford Street, London, S.E.1. The scheme deals in detail with methods of attracting recruits, and with the training of candidates on a regional basis in order to produce two grades of nurse; and there is a section on organization and control, with a view to the ultimate setting up of two registers, one for each of the two types of nurses. The scheme was drawn up by Miss Evelyn C. Pearce, Mrs. B. A. Bennett, Miss L. Snowden, and Miss G. B. Carter.

Central Shelter Sick Bay for City of London

A central shelter sick bay was opened by the Lord Mayor of London (Sir George Wilkinson) on August 27 at 66, Cheapside. In all the principal shelters of the City there are sick bays, but it was felt by the corporation that there should be a larger central clearing bay to which cases of illness occurring in the shelters could be brought for observation and later on removed to hospital if necessary, or sent home, supposing the patient to have a home, which is not always the case with these shelterers. Provision of this kind was at first arranged in Leadenhall Street, but the premises were required for another purpose connected with A.R.P., and eventually the Cheapside basement was acquired and adapted. It is actually a basement below a basement, and is regarded as one of the safest places in the City. It has been partitioned off into two wards, painted white, one for men and the other for women, with six beds in each, though the number of beds could be doubled if need arose. There is also a nurse's duty room with a doctor's table, and a well-equipped kitchen. The place is well lighted—each bed has its individual head-lamp; there is a carpet by each bed, and the

patchwork quilts and other pleasant features give a private-nursing-home touch to this subterranean refuge. There is also a small sterilizer, an electric cooker, a sink with warm water laid on, and a central heating installation. At this level there are chemical closets for use if necessary, but water closets are installed on the floor above. The Lord Mayor stated that the Ministry of Health had supplied the beds, the W.V.S. the bed drapery and clothing, and Messrs. Evans Sons Lescher and Webb the drugs and dressings, surgical instruments, trolleys and trays, cupboards and lockers, and the kitchen equipment. Alderman Key, commissioner for shelter for the London Region, speaking appreciatively of the corporation's action, said that having visited the areas of all the ninety-five local authorities in the London area it was no mere formality to say that some of the best shelters were in the City.

Middlesex Hospital Standing Up

Annual reports of hospitals, which used to be dull reading, are now often pages of adventure. Thus the report of the Middlesex Hospital describes two occasions on which the hospital was damaged in air bombardment: the first when two upper floors of the central block of the out-patient department were rendered unsafe for use, and the second, early this year, when there was a direct hit on part of the cancer wing. The report pays tribute to the magnificent work of the hospital staff, medical and lay, in these emergencies. To exemplify them it refers to certain members of the medical staff. Dr. H. E. A. Boldero, Dean of the School, adapted the work of the hospital to wartime conditions before taking over the duties of a group officer in the sector which is based on the Middlesex. Dr. H. L. Marriott further developed the wartime organization until his special work on blood transfusion took him into the R.A.M.C. Dr. Alan Moncrieff made the final preparations for the great test of air bombardment. "He [Dr. Moncrieff] stands for all sides of our work—tireless, firm, patient, and good-humoured in all circumstances." At the end of last year he left the hospital on transfer to Aylesbury, where the Middlesex staffs two hospitals, wholly in the one case, almost wholly in the other, with a total of some 1,500 beds. An annexe of 200 beds, capable of immediate expansion to 400 in the event of the hospital being put out of action, has been opened at Mount Vernon. The number of medical casualties attending the out-patient department during 1940 was 7,558, and the number of surgical casualties 11,013. In brief references to research the report states that investigations on the new chemotherapeutic drugs, particularly their effect upon war wounds, have been proceeding at the Bland Sutton Institute. In the Barnato Joel Laboratories problems of dosage in radiology have been studied, while in the Courtauld Institute of Biochemistry a number of studies have been made, including an investigation into the profound chemical disturbances of the body found in air-raid casualties. The preclinical students of the School are at the University of Leeds; the clinical students are posted at the Middlesex and at three sector hospitals, to each of which members of the honorary staff are attached and are continuing their regular courses of instruction.

Coroners' Inquests in London

The number of deaths reported to London coroners in 1940 was 10,129, being almost 1,000 more than in the previous year. Of these deaths, 3,747 occurred in hospitals and other institutions, including mental hospitals. Inquests were held in 2,979 cases. There was a small decrease in the number of suicides, and nearly one-third of the total of 538 were of persons over 60 years of age. Post-mortem examinations were made in 2,650, or 88.9%, of the inquest cases, and in 5,514, or 77.1%, of the cases in which it was decided that no public inquiry was necessary. In three cases a verdict of murder was returned, and seven inquests were held in connexion with executions. The number of people who met their deaths by accident was 1,695, being fifty-five fewer than in 1939. Only sixty-eight of the deaths were from drowning; fifty-eight were due to excessive drinking.

Dr. J. C. Drummond, professor of biochemistry in the University of London and scientific adviser to the Ministry of Food, has been elected Fullerian professor of physiology in the Royal Institution in succession to Sir Frederick Keeble.

Correspondence

Voluntary Hospitals

SIR,—I had a letter a few days ago from a friend who is greatly interested in our voluntary hospitals. In this letter he said, "I want to preserve the best features of our voluntary hospitals." I have heard and read the same words over and over again. Like many other phrases, such as "the freedom of the Press," "the public school spirit," etc., etc., there is a real danger of such phrases becoming mere parrot-like cries to be repeated *ad nauseam* in wartime, or with regard to important questions which are under consideration in connexion with post-war national policy.

Whenever I ask my voluntary hospital friends, lay and medical, what they mean "by the best features of the voluntary hospital system," I am either stared at with an expression of withering contempt, presumably for my complete ignorance, or I am overwhelmed with a Niagara-like cataract of words which are entirely meaningless, and I find it best to retire from the unequal contest. What I really want to find out, of course, is this: We have two parallel hospital systems in this country—the municipal and the voluntary. What are the particular virtues of the voluntary hospital system which are conspicuous by their absence in the municipal hospital system?

I wonder, Mr. Editor, whether one or more of your readers can supply the answer to this very important question?—I am, etc.,

Criccieth, Aug. 23.

FREDERICK MENZIES.

The Mental Defective in the Army

SIR,—In his paper on the mental defective in the Army (August 9, p. 187) Dr. F. J. S. Esher refers to three low-grade mental defectives who had been accepted for the Army by the National Service Recruiting Board. He found the mental age of these men to be 5½ years, 6 years, and 4½ years respectively. It would be interesting to know how the education authority dealt with them when at school. In my opinion, if the section of the Education Act relating to mentally defective children had been properly administered, they would have been notified to the mental deficiency authority. If this had been done, they would have been exempted from military service. While acting as No. 1 of a medical board, I was surprised when two of my former patients presented themselves for examination, for they had been under my care for years in the institution for mental defectives, but had been liberated since my retirement. Of course they were promptly placed in Grade IV. From these and other cases it is clear that there is some flaw in the present method of registration.

Dr. Esher discusses at some length the evidence that mental defectives are a hindrance to a modern Army, and commenting on his three cases says: "It would not have been difficult to discern that these men would never make soldiers if those responsible for their acceptance had been aware that mental deficiency was a definite hindrance to military efficiency." I have met several medical men who feel that this paragraph hardly does justice to the ordinary intelligence of members of the medical profession.

However, having established his first point, he proceeds to his second, which he describes as a discussion on easy and quick methods of detecting mental defectives. After thirty years' experience in examining all persons suspected of mental defect in a population of 250,000, I have come to the conclusion that there is no quick and easy method of detecting mental defectives; that in examining these suspects time and patience are essential and all hurry must be avoided; that while graduated tests are most helpful as contributory evidence too much reliance must not be placed on them—they may lead to erroneous conclusions—and that the claims for their mathematical accuracy cannot be sustained. I was therefore keen to read about this new discovery for detecting mental defectives by quick and easy methods. But, alas! from the development of the argument it is clear that *suspicion* and not the *detection* of mental deficiency was intended. Put quite simply, Dr. Esher's "aid in spotting the defective" is to inquire from the man how he got on at school and at work. This method is certainly quick and easy, but it

has the grave objection that the examiner has no means of verifying the truth of the replies given, unless, in the case of work, he write to the employer, whose response is uncertain and not necessarily unprejudiced.

To prevent the examiner being misled, Dr. Esher takes some pains to elucidate the vagaries of educational nomenclature, but I am not sure that this does not add to the confusion. For example, he tells us that in some schools the children in the "A stream" are the clever ones, while in other schools they are both clever and dull. He does not tell of the many other pitfalls for the uninitiated. One might think that since the elementary schools are divided into junior, intermediate, and senior, the children in the intermediate division would be intermediate in age or ability; but no, they are the academic cream and look upon the seniors as duds. Again, some authorities have classifications which are peculiar to themselves. In one city there is a large experimental school which is intended for children with behaviour problems. Another important special school, which Dr. Esher does not mention, is the industrial school—now called the Approved School—which title may be very misleading. I once said to a boy who was to go to one of these schools: "You have been in trouble a good many times for thieving; how were you punished the first time that you were in the hands of the police?" "Oh," said he, "they don't punish you up there; they put you on what they call 'approbation,' and now I am going to the Approved School."

With regard to work histories, it is obvious that among the unemployed many mental defectives will be found, and if other conditions as a cause of unemployment are excluded it is clearly due to mental deficiency; but to investigate "other conditions" would take a considerable time. With regard to unremunerative work, statements about income are proverbially unreliable, and no deductions can be drawn from these without verification.

With regard to types of occupation, all will agree that men engaged in the occupations mentioned in the paper are often mentally defective. Dr. Esher is certainly right in saying that holding one of these jobs does not in itself constitute a pointer to mental deficiency, but I would go further and say that many of these persons are thus occupied from choice, disliking any form of discipline or regular work; they like to be out of doors, free from restraint—nomads, who live by their wits. The gipsy cannot tell you how much money he earns, but in my experience is nearly always quick-witted, with a ready answer.

While it is quite true that data relating to school and work histories are useful as complementary evidence in suspecting mental deficiency, the basis of such suspicion should be obtained by direct observation of the person's general behaviour under examination and during conversation. The way in which he has filled up the questionnaire and signs his name in the examiner's presence is some indication. Without paying any regard to so-called stigmata of degeneracy, much may be read in the man's face. Is he slow to comprehend and respond? When asked to imitate the actions of the examiner, does he do so correctly? Is he slow and deliberate in speech and action? Instead of asking how he did at school, give him a passage to read and subsequently ask him to tell you what it is about. Terman's "lost ball in a round field" problem is a good one for testing comprehension, foresight, and judgment, and does not take long to apply.

It is well for the examiner to remember that while a person who is innately dull will make a poor soldier, it is also true that the highly educated man often appears stupid in simple matters. Excessive concentration, if it fits for analytical study, may unfit for the world and the Army.—I am, etc.,

Desford, Aug. 15.

ALLAN WARNER.

SIR,—We have read with interest Dr. F. J. S. Esher's article on the mental defective in the Army (August 9, p. 187), and also your editorial comment on this problem. We should like to subscribe our experience on this topic in the Lancashire area. Initially our attention was directed to this question in the early months of the war by the Mental Welfare Association for the area, who were astonished to find that many cases similar in type to those described by Dr. Esher had been passed as physically fit into the armed Forces. The Welfare Association communicated with the Ministry of Labour and National Service for the North-West, emphasizing the problem which such cases would create under military conditions. In the score of cases which were submitted it was noticeable that the patient's conduct and characteristics

had frequently obtruded themselves, and their records therefore were not only informative but clearly established how undesirable it was to recruit such individuals into the armed Forces. It is also noteworthy that in many instances the parents or relatives had approached the Mental Welfare Association to obtain discharge, fearing that the men's propensities would endanger the lives of their comrades—one, for example, told his mother that he was like James Cagney, the film star, when he sat behind his machine-gun, and she lived in terror lest he should mischievously press the trigger. One irate father exclaimed that it was cruel to take a boy away from home who had never previously been out of the family custody and, as we knew, had never learned to feed himself properly. These cases had been conscripted before the outbreak of war, and in many instances the parents admitted that the history of mental defect had been obscured from the medical board, as they had thought the six months under military discipline would greatly benefit the mental condition. After all, medical men can only make a minute examination when their attention is directed to some abnormality of history, and, when it is remembered that the majority of adult low-grade feeble-minded persons can maintain a fairly intelligent conversation, it seems unfair to hold the boards responsible. Such cases, with an average mental age of 6 years, should not be admitted to the Army; as Dr. Esher observes, this war is one of machinery, and in one or two instances such individuals were apt to get under the wheels and be killed.

Anxious to follow the fortunes of other mental defectives, we asked the various committees and workers interested in their social welfare to draw our attention to known cases of mental deficiency which had been passed as medically fit into the armed Forces. Just under 200 cases were collected. We were rather surprised to learn that many had enlisted prior to the outbreak of war, and according to the reports given to the visitors the majority had been retained in their units without their disability having been noticed or questioned. Their mental ages ascertained by school medical officers or ourselves averaged about 9 years. All had carefully concealed from the medical boards their unfortunate history at school or elsewhere. We sympathize with them. The rather indefinite label of mental defect attached to facilitate their educational disabilities or to aid a boy through adolescence because of wretched home conditions is not only a stigma but a handicap. These recruits from personal knowledge were well integrated and good natured, and those who had institutional records were known to work like galley slaves. Admittedly in our series there was a proportion of military misfits, but it was manifest from their histories that they were conspicuous on account of their abnormal mentation or inherent temperamental disabilities or, more particularly, their low-grade mentality. If they had been properly investigated these military rejects, amounting to 8%, would never have been admitted to the armed Forces.

In the ordinary community it has been ascertained that 8 in every 1,000 are mentally defective, but in practice 2 or 3 are notified. This would account for roughly 25% who would be able to give a history of mental defect, so that it is our opinion that it is not a satisfactory method of detection. The remainder attend ordinary day-schools until the age of 14 years, when they are allowed to leave from Standard VI as normal children. We are taught that our mental ages do not increase much after school age, and what we acquire is worldly sophistication—foresight, judgment, wisdom, prudence, and especially ethical considerations—and when one compares the subnormal population under restraint with the actual total it is clear that 97% transform themselves from backward scholars to successful adult citizens as and when they reach maturity. For example, many successful dockers are stated to have mental ages of 8 years, and the average mental ages of many races is about the same, but we would not cast the slur of mental defect upon them. Professor Cyril Burt in his *Subnormal Mind* (p. 89) states: "With adults the mental age can be taken as it stands for diagnostic purposes. Roughly speaking, a mental age of 8 years marks the borderline for the feeble-minded." Investigations have shown that three-quarters of the community have mental ratios between 30 and 110.

From all these evidences we are therefore of the opinion that the base-line suggested by Dr. Esher is far too high, ignores the cross-section of normal youths with low mental ages doing well under Service conditions, and would include a large proportion

of responsible citizens in the poorer quarters, and many now classified as dull would have to be labelled "mental defective." However, the position has to be faced that the 0.5% who slip through the medical boards form a formidable number of mental problems when the armed Forces reach into several millions. Our experience prompts us to make the following suggestion for weeding them out or grading them into their proper military niche. Reading tests, thanks to our psychologists, are thoroughly standardized; and the ability to read is a very complex mental process. If this test can be successfully passed by a candidate a diagnosis of mental defect can be almost excluded. If a base-line of 8 years is adopted a rough estimate of military fitness can be established. Having established a *prima facie* case of mental subnormality, the medical board could readily complete and interpret six further tests. For example, the ability to repeat six digits indicates roughly a mental age of 8 years, the ability to repeat seven digits a mental age of 11 years. The "cube imitation test" has been our main test; it is quickly applied, covers a wide range of mental ages, and its execution is most instructive. Our objection to group testing is that the whole process of studying mental suitability to military purposes is an individual one, and that many successful candidates would be excluded by their use and many unsuitable included.

We would stress that, where there is a wide variation in the ascertained mental ages—innate, reading, arithmetic, and on performance scales—the mental disability is such as to render the individual unfit for military service, and if he is put in the Army deterioration quickly ensues. In other words, the tests should result uniformly—if they do not, more than examination of intelligence is required. If tests such as Dr. Esher seems to advocate were adopted we feel that the British Army might soon be restricted to commissioned and non-commissioned ranks.—We are, etc.,

DAVID RUSSELL.

Manchester, Aug. 28.

Air-raid Noises in Psychotherapy

SIR,—Dr. J. C. Mackwood concludes his letter on air-raid noises in psychotherapy (August 23, p. 279) with the words, "It would be a catastrophe if we regressed to an orientation to neurosis that prevailed during the last war." I wonder why. I was in charge of the 350-bedded Seale Hayne Military Hospital for war neuroses during the last two years of the war of 1914-18, and I am sure that all who saw the working of the hospital will agree with me that the results obtained by my ten medical colleagues were extremely good. From what I have heard from several senior medical officers who have had extensive experience in both wars, the modern methods of treatment, however useful they may occasionally be in peacetime civilian practice, are much less successful than the treatment commonly used both in France and at home during the latter part of the last war. The very simple rapid methods of explanation, persuasion, and re-education were almost uniformly successful in the treatment of hysteria, so that it was rare for a patient to show hysterical symptoms for more than twenty-four hours after admission, and recurrences were extremely rare. The simple forms of psychotherapy so well described by the late Dr. T. A. Ross gave excellent results in the anxiety neuroses. From the end of 1917 we very rarely used such accessory methods of treatment as hypnosis, gross suggestion by faradism, etc. We found that simple persuasion was enough to induce our patients to take sufficient food, so that we should never have employed such undesirable methods as insulin poisoning, had insulin been then available—a treatment seriously advocated by two writers from an E.M.S. neurological unit in the *Lancet* of August 23.

Dr. Mackwood states that "the use of any method to produce further abreaction is not, as was held during the last war, merely to 'de-tension' by an escape of psychic pressure." Who believed in this (to me) quite meaningless jargon during the last war I cannot imagine.—I am, etc.,

Oxford, Aug. 24.

ARTHUR HURST.

SIR,—Dr. Frederick Dillon (August 16, p. 243) makes a fanciful flight to Mount Olympus. This parergastic excursion cannot be undertaken so light-heartedly by many in times such as these. The method of treatment described by Majors McLaughlin and Millar appears to be a serious contribution to wartime

psychotherapy; it may deserve criticism, but certainly not derision. Clearly, the intention of the authors is to use every possible method to conserve our available man-power—I am, etc.,

London, W.1, Aug. 18.

J. H. MELLOTT.

Flat-foot in the Army

SIR.—In two recent articles on flat-foot in recruits medical officers in charge of training regiments have reported attempts to improve the efficiency of substandard men (Captain R. T. Burkitt, June 28, p. 267; and Captain S. B. Sachs and Lieut. L. Gibson, July 26, p. 137). It is to be regretted that in neither instance do they appear to have planned their investigations in the light of current knowledge of the mechanism of the foot.

The men who formed the material of their researches were not sufficiently analysed in regard to postural disturbances. We are not told in how many subjects there were "squinting" knees, nor to what extent the feet were "pronated." Such data are indispensable if we are to assess the value of treatment. It is only by a preliminary study of the material under investigation that we can determine which flat-feet require treatment, and what should provide a rational basis for treatment.

It is well known that the longitudinal arch of the foot varies in height as an inborn or hereditary feature. There are racial differences: it is flatter in negroes than in Europeans. There are individual differences among the British, just as there are individual variations in the width of the foot or length of the heel. No disability occurs, and no treatment is required.

To be distinguished from a low arch of this kind is the flattened arch of the so-called "pronated" foot, in which the tibia, along with the talus (astragalus), is rotated inwards with reference to the foot. The connexion of this rotation with foot postures is dependent on the form of the joints between the talus and calcaneum (os calcis) and the obliquity of the axis of movement between the bones. The back of the heel becomes tilted inwards, as may be recognized on external examination; and, as a secondary effect, the fore part of the foot becomes *inverted* and abducted on the back part.

The fundamental character of the distinction between the naturally low arch and the pronated foot had already attained the textbook stage in Fick's work on the joints in 1911. Numerous references are to be found in more recent literature—for example, Morton, D. J., *J. Bone Jt. Surg.*, 1924, 6, 385; and Steindler in his monograph on *Locomotion in Man* (1935). Wiles (*Lancet*, April, 1937, p. 916) pointed out the association of a pronated foot with postural disturbances of the pelvis and lumbar spine.

One would have liked to have further information from the authors on various points to which they make reference. How often was "the high-arched foot beginning to give way" a foot with the pronated posture, and what were the degrees of pronation? What was the torsional form of the tibia in the subjects examined? What were the talo-calcaneal postures in those men who had "a marked degree of flat-foot" but had no complaints?

What we do know of the pronated foot entitles us to doubt whether a direct raising of the arch by pressure strikes at the root of the trouble, and whether the fault in a pronated foot is attacked by providing a pad that tends to "massage the arch of the foot" (Captain Sachs and Lieut. Gibson). Nor are satisfactory results to be expected from "deviation of the body weight to the outer edge of the foot."

It must be emphasized that disturbances of posture at the talo-calcaneal joint require attention to the orientation of the knee. A method of making a direct attack on the inversion and abduction of the fore part of the foot has been indicated in the exercise "(f) High Sitting or Sitting," p. 32 of the War Office publication *Physical and Recreational Training*, 1941.—I am, etc.,

St. Thomas's Hospital Medical School,
Godalming, Aug. 21.

ARTHUR B. APPLETON.

Burns from Penetrating Bomb Fragments

SIR.—I was very interested in Surgeon Commander Stabler's comments on my article of July 26 in your *Journal* (p. 119), and I think it more than likely that his explanation of burn necrosis of part of the colon may well have been correct. I must admit that this had not occurred to me. I agree with him also on the question of free drainage of the injured colon: this is generally regarded nowadays almost as a surgical axiom.

The comments on my treatment of the wound, however, I find to be severe and, as I think, unsound. The pack (which he harshly calls the surgeon's foreign body) which I inserted into the wound served three good purposes. (1) It arrested by simple pressure the many small venous haemorrhages which were taking place in the depths of the wound. (2) By being impregnated with sulphamilamide it probably had some minor antiseptic value. (3) It served to provide a track to the surface along which any infection which may have been introduced at the time of the injury might reach the surface rather than give rise to a deeply placed abscess. All these functions might be said to have been fulfilled by the fourth or fifth day, when such a pack is usually removed.

Lastly, I still think that the man was very lucky in that the perforated colon did not give rise to a spreading peritonitis, and had I realized at the time that the colon was injured or burnt I should still have opened the peritoneum and exteriorized the injured bowel.—I am, etc.,

London, W.1, Aug. 20

GEOFFREY E. PARKER.

Hypertonic Sodium Sulphate for Wounds

SIR.—Following on Dr. J. C. Lyth's references (July 26, p. 138) to his article on the application of hypertonic sodium sulphate to wounds (July 13, 1940, p. 53) I venture to offer my small experience to show the efficacy of this treatment in a variety of cases. In septic fingers, even with a pin-point puncture, relief is felt in the limb immediately on applying the soaked dressing. Dressings, moreover, may be left *in situ* for longer intervals than is usual with hot fomentations, provided evaporation of the sodium sulphate solution is prevented. In the case of varicose ulceration the ulcer heals and the indurated tissues surrounding it become supple. In hyperaemic conditions with no skin abrasions—as in sprains of the joints—there is relief of tension in the tissues: would this be due to action on the lymph fluid through an excessive secretion by the sweat glands in response to the application? And, lastly, in a variety of insect bites relief is immediate, and prolonged application reduces the swelling. Would it not be advantageous at the very least to make a wider use of so simple and effective a substance?—I am, etc.,

Burnham-on-Sea, Aug. 25.

T. PIRES.

Lectures on First Aid

SIR.—I offer the following comments on Mr. H. M. Stratford's remarks on the subject of first-aid lectures (August 23, p. 284).

If he is still an advocate of the use of the long Liston, may I call his attention to a paragraph in a recent work on fractures, which sums up the trend of modern thought: "In the Crimean War the mortality of gunshot fracture of the femur was 96%. In the early days of the great war it was 80%, but this was ultimately reduced to 20%, largely due to the introduction of the Thomas splint to the front line. The use of this splint on the battlefield itself accounted for an almost unbelievable improvement in the physical condition of men brought to the casualty clearing stations."

Such a statement may equally apply to first aid in A.R.P. and road accidents: in the latter many of us have had convincing proof. Why, then, is the use of this splint not more consistently taught by all first-aid lecturers? If thoroughly instructed, a first-aid party should be able to apply this splint, *in the dark*, in five minutes. Every house or row of houses should have at least one Thomas, and a T exhibited in the same way as stirrup pumps are advertised. There are many forms of folding Thomas already invented, but if price is the all-important factor 5s. is an absurd amount to be paying for the rigid type, which could easily be produced for half this price unpadding. This splint should be readily available, and is useless stored away in depots and posts. It is high time we got away from the bow-and-arrow days and profited by modern experience.

As to the tourniquet, this can be made by anyone, with automatic hold-fast, for about 6d., but here again thorough instruction should first be given in the use of a firm pad and bandage. The danger of the tourniquet cannot be overstressed, since it is such an obvious way out of a nasty mess. It must be the last resort and not the first. It is quite unreasonable to expect a

first aider who has never had any experience of bloodshed not to be somewhat panic-stricken when the real moment of action arrives. The only hope of efficiency is to give him or her the opportunity of attending, for at least one whole day, the casualty department of a reasonably large hospital. The method of sending large numbers on a personally conducted tour of an out-patient department is quite useless and merely hampers the work of the hospital.

Fractures of the upper arm can be efficiently controlled by pads and a broad bandage round the body, together with a collar and cuff for the arm; by a properly adjusted sling for the forearm. All fractures of the leg above the ankle are controlled and relieved by the Thomas. Padding and suitably applied bandages are sufficient for the ankle. If all the so-called long Listons (for many have not even got holes for an extension band) were collected to replace some of the iron palings and the latter made up into Thomas splints, many lives might be saved and much suffering averted. I am assuming that the instructor is not one of those who have never seen a Thomas in use outside a surgical ward.

It is unfortunate that there is not any small clip for the control of torn vessels at present available. A small soft metal seal attached to a coloured tape, which could be clamped on quickly and left in the wound, might be the means of saving many lives; artery forceps are expensive luxuries to throw away and are not too easy to obtain in large numbers. Innovations are, however, not much in favour unless there is a large contract for someone to handle!—I am, etc.,

Uley, Gloucestershire, Aug. 27.

J. G. FAYRER HOSKEN,
Major, R.A.M.C. (T.F.) (ret.).

Cardiac Arrest during Anaesthesia

SIR.—It is with the greatest reluctance that I comment upon Mr. Hamilton Bailey's article (July '19, p. 84) and subsequent letter (August 16, p. 243), and I hope that he will not think that I am criticizing him personally, as obviously he was not responsible for this disastrous series of tragedies.

No one will disagree with the excellent technique recommended for the treatment of cardiac arrest, which is, indeed, very similar to that given in modern books on anaesthesia. The omission to point out the importance of the right auricle as the site of cardiac puncture has already been commented upon. Two suggestions are made, however, which are so erroneous that I do not think they should pass unchallenged.

The first is the incidence of primary cardiac failure under general anaesthesia. Many full-time anaesthetists have passed the whole of their professional careers without seeing such a disaster. Others have had from one to four of such incidents. I personally have had two cases under general anaesthesia (one of which recovered completely after cardiac massage), and have seen one under a combination of rectal basal narcosis and local, and one under a pure local analgesia. As the average anaesthetist gives at least 60,000 administrations during his life, it seems unlikely that with reasonable skill the incidence of primary cardiac failure under general anaesthesia exceeds 1 in 20,000. Mr. Hamilton Bailey states that he has performed cardiac massage forty times in twenty years. Assuming that he has craged 1,000 operations per year, the suggestion is that primary cardiac failure has occurred about once in 500 cases, an incidence 40 times as high as the estimated average.

In his subsequent letter Mr. Hamilton Bailey states that *pure* chloroform has not been used, thus implying that chloroform diluted with ether and other drugs is less likely to cause cardiac arrest. This is an error which is unfortunately widespread and has been the cause of many avoidable fatalities.—I am, etc.,

St. Albans, Herts, Aug. 20.

C. LANGTON HEWER.

SIR.—Mr. Hamilton Bailey's reply (August 16, p. 243) that *pure* chloroform (the italics are mine) was not used on his cases evades the point of my letter, and suggests that he holds an old-fashioned and fallacious belief in the greater safety of chloroform mixtures. In fact, chloroform is liable to cause sudden unexpected cardiac arrest whether it is given alone or in combination with any other anaesthetic. It is for this reason that English teaching hospitals have discouraged its use for so many years. A similar tragedy is virtually unknown under ether anaesthesia.

I repeat that Mr. Hamilton Bailey's host of catastrophes could only result from grossly incompetent anaesthetists or, and far more probably, from the widespread use of chloroform.—I am, etc.,

Manchester, Aug. 21.

H. J. BRENNAN.

Chloroform - Ether Sequence

SIR.—I was interested in the letter by Dr. L. S. Woolf (August 23, p. 282). I am one of the nearly extinct species—namely, a rag-and-bottle anaesthetist. After forty years' experience I still prefer the chloroform and ether sequence, and my cases run well into five figures without any accidents (touch wood). I quite agree with Dr. Woolf in his remark, "Why do away with open ether?" The great objection to ether is its unpleasant smell, but apart from this it is very safe, and, personally, I have found in the open method no inconvenience from its use by causing bronchial troubles afterwards. Because of its smell I always induce with chloroform.

Chloroform is safe if you give 100% attention to your patient and none to a machine. My patients find it quite a pleasant induction, and I have used it for every kind of operation—from small ones in my surgery and children at a dentist to removal of the tongue and empyema of lung and even for diabetics. My patients have very little vomiting, and the method is not extravagant in ether if the right quantity of gauze on the mask is strictly adhered to; I use three folds of three-ply gauze.

My main tips are: (1) Give confidence to patients, especially children, by a friendly chat during induction. (2) Watch the breathing carefully. (3) Don't touch the patient's face with mask till unconscious. (4) Give atropine in elderly or bronchial subjects. (5) Never use a chloroform-ether mixture.

I am not in any way writing against the use of other methods, and realize their value in other hands, but I do maintain that my simple method compares very favourably with the more mechanical methods. My deaths are nil, and patients and surgeons seem satisfied. I might add that I have had experience in the use of various types of machines, although I do not pretend to be an anaesthetic specialist.—I am, etc.,

Dorking, Surrey, Aug. 26.

A. H. FARDON.

Treatment of Impetigo Contagiosa

SIR.—In the treatment of impetigo I am interested to see at last in the article by Dr. Carslaw and Mr. Swenarton (August 16, p. 225) a reference to the use of an aniline dye. For years now I have used a 20% solution of gentian violet, as recommended to me by Dr. Heimburger in China at the Shantung University Medical School. I presume it is in common use in the U.S.A. I have found it valuable in any staphylococcal infection. Remove the scabs and paint on the dye, which will dry up the serous discharge. Then simple ung. zinci usually suffices to complete a cure. Impetigo, so commonly associated with pediculosis capitis, is only curable after dealing with the nits in the hair by kerosene.—I am, etc.,

Liverpool, Aug. 20.

FRED R. CRADDOCK, M.B.

SIR.—Much controversy seems to have arisen recently about the treatment of impetigo contagiosa. In a recent letter published in the *Journal* Lieut. E. Snell (August 2, p. 178) suggests that failure of improvement with routine treatment is due to reinfection from the "dirty, greasy, high-collared neck of the tunic." I would like to point out that, as the name implies, impetigo contagiosa is a contagious streptococcal skin infection, and that good results are only obtained in the sick bay or a camp reception station and if all precautions for isolation are taken. The patient's clothes and bedding should be treated by steam to check possibility of spread and reinfection.

Recently I have used Squibb's quinolor ointment daily with the scabs cleaned with a concentrated solution of sodium bicarbonate before application of ointment. The results have been very satisfactory and the patient is usually discharged cured after a week.—I am, etc.,

M. H. L. DESMARAIS,
Capt. R.A.M.C.

Aug. 8.

Antiseptic Snuffs

SIR.—I was interested to read the paper by Drs. Delafield and Straker (August 16, p. 221).

Thirty years ago I experimented with a number of formulae, when the choice of suitable drugs was more limited than it is to-day. No attempt was made to verify their efficiency bacteriologically, but in actual practice I found that the most efficient were the most objectionable to use because iodoform was the chief ingredient. There was a time when every hospital reeked of iodoform, and for some reason or other the public used to associate the smell with syphilis, which was an added objection. Yet many patients who had derived benefit from "iodoform snuff" continued to use it in spite of its abominable smell. With regard to colds, my experience was that in many cases they were rapidly aborted and, apparently in some, prevented.

The following are some of the formulae I used: (1) CHI., 1 part; acid. boric., 20 parts. (2) CHI., 1 part; bismuth. subnit., 20 parts. (3) CHI., 1 part; bismuth. subgall., 20 parts. (4) CHI., 1 part; bismuth. salicyl., 1 part. Their rapidity of action appeared to be increased if used about an hour after irrigating the nose with one pint of normal saline.

All the formulae appeared to be equally effective, which was attributed to the iodoform, so No. 1 was commonly employed for the sake of economy. I eventually abandoned its use because most patients objected to the abominable smell.

It would be interesting to learn the effect of iodoform on the pneumococcus *in vivo*.—I am, etc.,

Brookwood, Surrey, Aug. 16.

H. M. STANLEY TURNER.

Somatic Taeniasis and Cysticercosis Epilepsy

SIR.—To the six records noted by Dr. Cecil W. Ewing and to his own case (August 23, p. 263) can be added two others recorded in the *British Medical Journal*.^{1 2} The diagnosis in my case was made because I happened to remember a paragraph in Choyce,³ which mentions "a case of this kind under the care of Rose Bradford, the patient, a soldier aged 30, was admitted to hospital on account of epileptic attacks. Multiple small tumours, one of which was excised and proved to be a cysticercus, were present in the subcutaneous tissues of . . ." I wrote to my patient about one year after his illness, and to my surprise he replied that he was well and working.—I am, etc.,

Harrogate, Aug. 23.

T. VIBERT PEARCE.

Emetine in Liver Abscess

SIR.—There are one or two points to which I would like to refer in the very interesting article on the surgical complications of amoebic dysentery (August 23, p. 261).

Mr. H. W. S. Wright states that paracentesis is necessary in the diagnosis and treatment of liver abscess. I suggest that after full physical examination with x rays to help, such a proceeding is quite unnecessary where the abscess grows upwards, and even less so when it tends downwards. Another point is that these abscesses are often multiple, and who, having found the first and nearest abscess, would go on searching for others? Yet under emetine the whole condition clears up. Mr. Wright emphasizes that the amoebic abscess is a cold abscess and should be treated as such. Does Mr. Wright recommend repeated aspirations in a psoas abscess or only when there is a risk of rupture or of damage to adjacent structures?

For many years I have urged moderation in the use of emetine, and I gave emetine in liver abscess cases: 1 grain for three consecutive days, missed four days, emetine 1 grain for two days, missed five days, emetine 1 grain for two days or one day, according to progress, missed five or six days, and then wound up the course with 1 grain on one day in each of two weeks. This method produced very satisfactory results, whereas after the heavy doses suggested by Mr. Wright and generally recommended I have had to deal with patients suffering from overdosage with this very wonderful drug. I regard emetine as the nearest approach to a miracle-worker that I have come across, but the resistance of the individual, which has grown and multiplied

during the slow growth of the abscess, is of very great importance and should be taken into account. The case which made me realize that there was such a factor was that of a patient who had been expectorating liver abscess pus for two months, and whose expectoration stopped four hours after giving emetine 1 grain. Finally I would add that my last case of liver abscess was successfully treated as an out-patient on the lines I have given above.—I am, etc.,

Southwater, Sussex, Aug. 23.

V. S. HODSON.

Diagnosis of Yellow Fever

SIR.—In his letter in your issue of August 16 (p. 247) Dr. G. E. H. Le Fanu has done well to draw attention to the old but very important problem of the diagnosis of yellow fever. A medical practitioner who works in an endemic area is faced with a serious question when he encounters a possible case: He cannot escape from the task of endeavouring to make a diagnosis. During my period of service on the Gold Coast medical officers in their efforts to reach a decision were accustomed to place considerable reliance on frequent examination of the urine. The history of outbreaks showed that early cases were generally overlooked. Later on, when an increasing sick rate or death rate from a fever aroused suspicion, the finding of a marked and increasing amount of albumin in the urine of such cases from the second or third day onward together with a diminution in the quantity passed was in practice considered as conclusive in favour of yellow fever.

For the benefit of medical officers in East Africa, who may before long find themselves confronted with yellow fever, I would say that in West Africa a diagnosis was usually made in the presence of the following group of symptoms: sudden pyrexia, 101° F. (or less) to 105° F. (or more); prostration, early and marked; headache, severe from the start, mostly frontal or orbital with congested eyes and turgescence of the skin of the face; loin ache or backache; urine—a rapidly increasing albuminuria from the second or third (or, rarely, the first) day onward with a steady reduction in the volume of urine passed: the urine was tested frequently and measured daily. Other symptoms, such as epigastric pain and tenderness, or a small pointed tongue red at the tip and edges, were taken as confirmatory. Jaundice and haemorrhages were later symptoms. Jaundice is often hardly noticeable, especially in mild cases.

The importance of the urinary findings in the clinical picture of the disease was stressed by Dr. H. Beeuwkes of the Rockefeller Foundation in a paper on the clinical manifestations of yellow fever in the West African native as observed during four extensive epidemics of the disease in the Gold Coast and Nigeria (*Trans. roy. Soc. trop. Med. Hyg.*, June, 1936, 30, No. 1).

Apart from the importance of an early diagnosis in the interests of public health the question of treatment arises. It is vitally necessary to withhold all food in the early days of the illness. African patients often object to such a restriction. I have seen the ingestion of food followed rapidly by a profuse haematemesis and death.

There is unfortunately as yet no quick and easy test for the disease in the early stages. It follows, therefore, that medical men who practise in an endemic or threatened area ought to make themselves as familiar as they can with its clinical manifestations so that they may be in a position to take action when they meet with a possible case. In an endemic area a sudden pyrexia with severe headache from the start and with early and increasing albuminuria should be regarded as highly suspicious and sufficient to justify the prompt application of local preventive measures.—I am, etc.,

Bristol, Aug. 25.

D. DUFF.

Subcutaneous Ligature of Varicose Veins

SIR.—I have followed with great interest the correspondence arising from Dr. Russell's paper on subcutaneous ligature of varicose veins. From personal experience I can support Dr. Russell's claim that his technique is simple, painless, and safe. It must be admitted, also, that the immediate results are generally very satisfactory, but they are no more effective and no more reliable than the results that can be obtained by injections alone.

There is nothing new in subcutaneous ligature of varicosities. Heister (1683-1758) used it and states that it was practised by

Gauicus. Davat (1833) reported several cases treated by subcutaneous ligature, as did Schede (1887). I used the method on many occasions before the introduction of sclerosing therapy. Like many others, I hoped that injection therapy was going to prove a panacea for all varicosities. Time, however, brought disillusionment, and in 1927, in an endeavour to improve on the results obtained by simple injection in cases of gross varicosities with valvular incompetence, I started to combine injection with subcutaneous ligature of the saphenous vein in the thigh, using a technique almost identical with Dr. Russell's. Like Dr. Russell, I was greatly impressed by the immediate results, and during the following three years I used the method between sixty-five and seventy times. I gradually abandoned the method because I found that equally good immediate results could be obtained by the simple non-operative technique which I learnt from my friend Dr. Stuart McAusland and which he described in the *Journal*. Moreover, I found that recurrences, though often delayed for two to three years, eventually appeared in over 60% of cases.

The next step in my endeavour to find a cure for cases of gross varicosities was to divide the saphenous vein in the thigh above the varicosity and at the same time inject the distal end. Here again the immediate results were excellent, but of 160 cases treated in this way between 1930 and 1936 20% eventually showed gross recurrence, and in many more minor degrees of varicosity returned. Not more than 50% could be classed as permanent cures.

In 1932 I started to tie and inject the saphenous vein at the saphenous opening, and by 1937 I was convinced that this procedure (described in conjunction with Mr. Dodd in the *Lancet* of June 6, 1940) gave the best results. Unlike all the other methods, the merits of this technique have impressed me more and more as my experience increases and the years go by. Unfortunately the war and my Service commitments prevent my making an accurate follow-up of the 462 cases I have treated by high ligature and injection, but at all events the recurrence rate has been negligible.

It is remarkable how many of those who have the largest experience of treating varicose veins (Dickson Wright, Ochsner and Mahorner, H. Dodd, Faxon) have, in dealing with varicosities in which the Trendelenburg test shows valvular incompetence, independently been forced by experience to the conclusion that:

1. Injections alone are followed sooner or later by recurrence in a very high percentage (about 60) of cases.
2. Ligature combined with injection of the saphenous vein in the thigh is followed eventually by nearly as high a percentage of recurrences as simple injection.
3. Ligature and injection of the saphenous vein at its junction with the femoral vein gives a permanent cure in not less than 90% of cases. If Trendelenburg's test is positive, then to divide or block the saphenous vein anywhere below its junction with its terminal tributaries and with the femoral vein is as futile as to be content with removing the distal half of a hernial sac.

It will indeed be unfortunate if its simplicity should popularize a method which is based on the results obtained in only some fifty cases, none of which have been followed up for more than two years.

Dr. Russell's method is not only based on a complete misunderstanding of the mechanics governing the formation and recurrence of varicose veins, but has been tried and found wanting by many surgeons who have given it a longer and larger trial than he has.—I am, etc.,

Activity of Tuberculosis

SIR.—In his letter (August 16, p. 245) with reference to activity of pulmonary tuberculosis Dr. Lawrence Roberts raises a question on which there is evidently some difference of opinion. He suggests that "when a patient has a demonstrable tuberculous lesion in the lung and when he has sputum which contains tubercle bacilli then the lesion is, by definition, active." It would, I think, be unwise to adopt the suggestion that the presence of tubercle bacilli in the sputum should be regarded as an indication of activity, as if the conception of activity is related too

closely to the presence of positive sputum it will lose much of its value; a negative sputum has no relation to activity.

As Dr. R. Wright points out in a letter in the same issue of the *Journal* (p. 246), patients with positive sputum are often able to continue their work without harm to themselves; if the disease in such cases is regarded as being active then the description ceases to have any practical value, since a diagnosis of activity implies that rest and treatment are needed. I would agree that a case with positive sputum is potentially active, but then so may be a case with negative sputum, so that no useful purpose is served in drawing a distinction.

I would suggest that if the word "activity" in this connexion is to have any practical value it must mean constitutional disturbance resulting from the tuberculous lesion, and the assessment of this in a doubtful case not showing the more obvious signs of pyrexia and toxæmia would be made by clinical observation and by such investigations as the blood picture and response to exercise.—I am, etc.,

Northwood, Middlesex, Aug. 21.

D. G. M. EDWARDS.

Communal Feeding in Schools

SIR.—Dr. Letitia Fairfield's letter (August 9, p. 211) deserves support. Dr. G. W. Fleming (August 23, p. 282) enumerates the two main points of Dr. Fairfield's letter and answers each one. First, there is the suggestion that the taking of meals together is a strong binding element in family life, and against this is placed the fact that in the middle and upper classes the majority of children spend their lives at public schools, and the disastrous effects of this communal feeding have never become manifest. Secondly, there is the idea that the mother should be helped in her task of feeding children rather than be relieved of the task, against which is placed the suggestion that the mother is helped if the children are given properly balanced school dinners. Dad and Mum, Dr. Fleming suggests, can still preside at breakfast and tea without the loss of the healthy vitamin diet so difficult to ensure when all the meals are taken at home. Dr. Fleming, as medical officer of health, naturally looks at life from the physical side. Far from deploring this at the present time, it can almost be said that we can assume medical officers of health are looking after the nourishment of children just as they are preventing the outbreak of preventable infectious diseases.

It will be a great mistake, however, to think that in answering Dr. Fairfield's main points in this way the sting of truth has been taken out of her letter. In my opinion an extremely important problem has been raised—one which could be discussed at great length. In this letter I would only ask those in Dr. Fleming's position to bear in mind the possibility that there may be things in heaven and earth not dreamt of in their philosophy. Evacuation has taught many who were formerly unprepared for the complications arising out of feelings, fantasies, and superstitions to recognize and respect these phenomena. Now, instead of holding that they are beneath contempt, people are a little more prepared either to try to understand them or to consult those who make it their job to study the whole human being instead of the body only. For instance, can Dr. Fleming say offhand how important to a mother is the cooking of a dinner for her husband and children? How far, if she does not cook their main meal, is she deprived of a test of her own goodness, which she needs, and how far does the substitution of communal for family feeding increase the incidence of maternal depression? If he knows the answer to these questions and a few similar ones, he is entitled to influence our opinion of Dr. Fairfield's suggestions. I can myself state that, whereas the voluntary and somewhat irregular communal feeding of children can be successful, not only physically but also in regard to emotional development, the same thing as a compulsory and permanent feature would lead to some surprising disappointments to those who provide lovely and cheap meals.

My suggestion, then, is that no one doubts that what Dr. Fleming says is true so far as it goes, but that it is dull if we as doctors always stop short as soon as we finish the purely physical sides of a problem. If we do this we cease to be consulted—as happened over the problems arising out of evacuation, which were tackled by the teachers and not by the doctors—and we lose our right to expect our advice to be followed by the parent that he.—I am, etc.,

London, W.1, Aug. 21.

D. W. WINNICOTT.

SIR.—I regret that my copy of the *Journal* did not reach me in time to permit of an immediate reply to Dr. G. W. Fleming's letter (August 23, p. 282). Fortunately another letter on the same page must have helped your least imaginative readers to picture the future planned for the working-class child by our municipal Führers. Dr. Joan McMichael puts in an eloquent plea for the "extension of the crèche and day-nursery system not as a necessary evil but as a useful and permanent contribution to child welfare." She further quotes with approval the example of Soviet Russia, "where perhaps the majority of women prefer to continue their careers after marriage," while doctors and nurses and other trained staff pursue them in caravans laden with suckling infants. Then we learn from Dr. James Kerr (July 26, p. 137) that nursery schools are "the right of every child from 2 to 5 years of age" (a proposition for which there is more to be said than for any other in the programme, if restricted to town children). At 5 years Dr. Fleming peremptorily demands "compulsory and universal school feeding," even though this means that the task of providing food does ultimately go out of the mother's hands altogether, a prospect which he does not consider "calamitous."

Work out this programme in terms of (a) cost to a war-exhausted nation and (b) the amount of time a mother would spend with her children and the influence she would have over them. To quote middle-class experience with public schools is no answer, for the whole social background is different. Moreover, Dr. Fleming should be aware that the cost of educating and feeding children away from home has become such a serious burden on the middle and professional classes that it is very doubtful if the system can continue after the war. Its spread in this century has certainly not improved home life, and it is considered to have had a serious dysgenic effect on the nation, as Dr. Leybourne shows in her excellent study of *Education and the Birth Rate*. The statement that there is no reason why "school dinners should appreciably increase the taxpayer's burden" is astounding, especially if the dinners are to be used for teaching cookery. He admits that only about 11% of school children are noted as ill nourished. Even if the figure were 20% it would be worth while to see what the working mother, helped by family allowances and improved education, could do before burning down her home to get one roast pig. She would surely be happier cooking a dinner than in the factory or field or day-dreaming at the pictures.—I am, etc.,

Aug. 30.

LETTIE FAIRFIELD.

Speed and Road Casualties

SIR.—It is to be hoped that the improvements in the social order to which we look forward after the war will include a sweeping and drastic reform of our road arrangements. For over twenty years the British people have regarded a fatal accident on the Great Western Railway as front-page news for days, and a single murder case as affording excitement for weeks, but have accepted, apparently with resignation if not equanimity, the daily killing of over twenty people by (or "arising out of the use of") motor vehicles. Probably this attitude is largely the result of motoring propaganda centred around the famous slogan, "Speed in itself is not dangerous" (nor is morphine so long as it remains in the bottle!). Surely our profession, through the B.M.A., has an important part to play in "debunking" that slogan and getting speed relegated to its proper category.

The effect of speed on the mind inadequately equipped to indulge in it is typified by the driver who hurtles through a country village with a scowl on his face and his finger hard down on the horn-button, as if the outcome of the war and continued progress of civilization depend on his not taking his foot off the accelerator. The furious indignation aroused by any circumstance causing him to apply his brakes implies that his senses of proportion, humour, dignity, and even decency are temporarily anesthetized. The risks he will run for the sake of overtaking the car in front (for what purpose he would find it hard to explain) are not such as would be incurred by anyone in his right mind. I suggest that speed should be regarded as a psychological intoxicant and subjected to something analogous to the Dangerous Drugs Act Regulations.

Whatever may be one's feeling about motoring, the fact remains that the motor vehicle has during the past twenty years

killed far more people in this country than all the dangerous drugs plus all the railways; and what makes it worse is that the drugs only injure their addicts, whereas speed kills other and innocent people. The railways are safe because those deputed to drive potentially lethal machines, even on private tracks, are restricted to a relatively small number of men of long experience and proved reliability who, after that, stand to lose their job if they make one mistake. If motoring is not to remain a blot on our civilization second only to war some such methods of regulation will have to be applied to the roads.—I am, etc.,

Saltash, Aug. 22.

W. H. SPOOR.

Control of Venereal Disease

SIR.—The editorial on this subject in the *Journal* of August 9 (p. 208), which commented on the discussion at the meeting of the Medical Society for the Study of Venereal Diseases of July 26, reads as follows:

"It appeared to be the majority feeling at the meeting that some measure of control was called for, but . . . there was not a near enough approach to unanimity to make it seem advisable to send a resolution to the Government."

This contrasts oddly with the annotation appearing in another medical paper, from which I quote:

"Is any form of compulsion practicable? Though no vote was taken the meeting appeared to be unanimously of the opinion that it was."

Is it mere coincidence that the policy of the *Journal* has been consistently one of opposition to compulsion, whereas the policy of the other paper has tended to favour it?—I am, etc.,

Brentwood, Essex, Aug. 12.

ROBERT FORGAN.

* * We fail to follow Dr. Forgan's observations on coincidence. The article on control of venereal diseases published on August 9 was, we believe, a correct account of what took place. Our reporter took down verbatim the following remarks made by the president of the society, Colonel L. W. Harrison: "I feel that there is not enough unanimity for us to instruct our secretary to write in the way I have suggested, but I could myself say that there was a strong feeling expressed. . . . I do know that there has been a fair amount of feeling expressed at this meeting that something should be done if it could be properly safeguarded. However, we will not go any further with it." It would seem that our summary was accurate; and we expressed no opinion on the matter.—Ed., B.M.J.

Diagnostic Bacteriology

SIR.—It is not "impossible to dispute" anything. Your reviewer of *Methods for Diagnostic Bacteriology* is particularly opinionated in stating (March 29, p. 482), "It is impossible to dispute that Pugh's or Albert's stain gives a much more characteristic picture" in diphtheria diagnosis than methylene blue. I have no experience of Pugh's stain, but I have found Albert's open to the objection which, though perhaps in greater degree, applies to Neisser's: over-emphasis of the metachromatic granules at the expense of differential staining of the bacillary body, which is a much more important diagnostic feature, and which is better displayed, and the granules sufficiently well, by a good Loeffler's methylene-blue technique.—I am, etc.,

Public Health Laboratories, Cairo, June 6.

B. R. SANDIFORD.

An appeal for salvage, particularly for waste paper, has been issued by the salvage department of the Ministry of Supply as a forerunner to the salvage drive to take place throughout Greater London from September 13 to 27. Businesses are asked to turn out all old correspondence, records, ledgers, price lists, etc., which have been put on one side against possible use "some day"; also those old directories and guides still retained but infrequently used. This appeal may also be made to doctors, since it is not unusual for them to have records, ledgers, trade circulars, packing material, etc., stored away in such places as the back of the surgery or the garage. Not only are all kinds of waste paper required, but any quantity, large or small, since even one old envelope will make a cartridge wad.

Obituary

JOSEPH NELSON, L.R.C.P.&S.Ed.

On August 16 (writes a colleague in Hull) there suddenly passed from our midst Dr. Joseph Nelson, one of the best-known and most highly respected general practitioners in the East Riding of Yorkshire.

"Joe," as he was familiarly known to all, was born in Limerick of Protestant parents, and came to England with a brilliant school reputation to study medicine at the Westminster Hospital. He qualified in 1894, and held a post at Lewes Infirmary and Warwick County Asylum before coming to Hull as resident surgeon to the Hull and Sculcoates Dispensary. After ten years in this post he took up general practice. Although not in robust health for some years, he had been for many months especially well, and indeed, although somewhat indisposed for a day or two, he was on a medical board the very night before he died. He played an extremely active part in all that pertained to general practice, and more especially to panel practice. He had always taken a very great interest in the work of the British Medical Association, and was chairman of the East Yorkshire Division in 1922-3 and president of the East Yorkshire and North Lincolnshire Branch in 1928. In national health insurance he was not only profoundly interested but was quite an authority on all the Health Insurance Acts. He was a member of the Hull Insurance Committee for nearly thirty years, and for twenty-one years he was secretary of the Local Medical and Panel Committee. The last meeting which he attended, strange to say, was the twenty-first anniversary—day and date—of his taking over this position. He carried out his duties with such skill and enthusiasm that he practically was the Hull Panel Committee. His opinion on vexed questions was very much sought after and very willingly given. Indeed, he enjoyed a national reputation, and was one of the best-known figures at the Panel Conferences and Panel Dinners for many years. He was possessed of a marvellous memory, a quick wit, and very ready spontaneity of speech, making many remarkable extempore contributions to discussions. As a secretary he had an infinite capacity for taking pains, and his efforts were so wonderful that no one can certainly be found to equal him as secretary of the Hull Medical and Panel Committee. He was originally appointed chairman of the East Yorkshire Medical War Committee, but felt he could not carry on and resigned after a few months. He was co-guarantor of the war agreement for absentee practitioners, and continued an enthusiastic member of the committee until the end. He attended at the recent Panel Conference in London as a delegate from Hull, and was very disappointed indeed with its result. He was a fearless and outspoken critic, and his criticisms, especially on the present capitation question, are well known to the I.A.C. He felt much disappointment at the introduction of the new group into health insurance, and was very indignant that the profession was not consulted before it was introduced. He was chairman of Group C of the Standing Joint Committee and was to have convened a meeting at Leeds shortly to discuss methods of tackling the capitation question.

Dr. Nelson contributed many papers to learned societies in Hull, and was a great student of Nature, especially of bird life in Yorkshire. For many years he was a pillar of the Labour movement in his district, although recently he did not take any active interest. He remained exceedingly friendly with Robert Blatchford, and was on the friendliest terms with Hyndman and many whose names were household words in Socialist circles. He and his wife were instrumental in organizing the great Hull dock strike some thirty-three years ago, and at one time he was trustee of the Dockers' Union. His pleasant Irish intonation will be much missed at medical meetings in Hull. Indeed, his loss is an irreparable one to the whole profession, which mourns the loss of one who truly gave his life for his fellows, and the sympathy of all goes out to his family of three daughters and a son, who is now serving as a slight-lieutenant in the R.A.F.

The death occurred on July 24 of DAVID HUEY, F.R.C.S., J.P., at his home, Bushmills, Co. Antrim, in his eighty-fourth year. He had been for over half a century the local dispensary doctor, and throughout those years he was the embodiment of all the characteristics of the country doctor. He was guide, philosopher, and friend to a large district and his influence was felt in every sphere. Such was his keenness in his work that he proceeded to his Fellowship of the Royal College of Surgeons, Edinburgh, at the remarkable age of 67. He was a regular attendee at clinical meetings of the Ulster Medical Society and B.M.A. He had been a member of the Association since 1908, had been a representative at ten Annual Representative Meetings, and was chairman of the North-East Ulster Division in 1928-30. Dr. Huey's main hobbies were salmon fishing in the River Bush and golf—he had been for years captain of the Bushfoot Golf Club, for which he provided a new clubhouse. He was a prime mover in everything to benefit his community, and took an outstanding part in the management of local education, particularly as a governor of the local secondary school. He had presided regularly at the local petty sessions for many years. He was more than a pillar—almost the foundation—of Dunlacy Presbyterian Church, where he worshipped without fail every Sunday and to which he was the principal benefactor throughout his life.

We regret to announce the death at his home in Wimpole Street, London, on August 8 of Dr. BERTRAM SHIRES, who was well known for his work as a radiologist during the past twenty years. Bertram Shires had been a medical student at the University of Edinburgh and graduated to M.B., Ch.B. in July, 1914. Soon after the outbreak of the last war he received a commission in the R.A.M.C. Special Reserve and reached the rank of major. On returning to civil practice he decided to specialize in radiology and studied for the Cambridge D.M.R.E., which he took in 1921. Joining the x-ray department at St. Thomas's Hospital in 1924 as chief assistant, he was appointed assistant radiologist three years later, and became director of the department in 1939. Dr. Shires was also honorary radiologist to the Hospital for Sick Children, Great Ormond Street, and consulting radiologist to the Infants' Hospital, Vincent Square. He went on living in London during the present war, and spent much of his time travelling to and from Godalming after St. Thomas's moved part of its work there last April in consequence of the severe bombardments.

Dr. SPENCER SMITHSON DUNN, who was driven out of Southampton by enemy action, died recently at the age of 82, after years of suffering patiently borne. He graduated M.B., C.M. of the University of Aberdeen in 1888, and practised for a time at Sheffield. While on military service in the South African War he went forward into heavy fire with two volunteer stretcher-bearers to bring back a severely wounded sergeant, and got him to a place of safety. For this gallant deed he is believed to have been recommended for the Victoria Cross. During the last war Dr. Spencer Dunn did good work in various capacities. Gradual deterioration of health caused him to retire from active practice some years ago.

The death of Dr. T. J. L. FORBES of Whitworth deprives the Rochdale Division of its senior member. After graduating M.B., C.M. of Glasgow University in 1894 he held resident posts as house-physician and house-surgeon at the Western Infirmary, Glasgow, assistant medical officer, Riccarton Asylum, and Glasgow, assistant medical officer, Glasgow Royal Maternity Hospital. In 1899 he went to Whitworth as partner to Dr. A. Welch, whose daughter he married, and spent the rest of his life in this Lancashire upland valley. He devoted almost the whole of his activities to the service of his patients in his extensive practice, and this devotion was returned in large measure by the whole-hearted affection of the patients whom he served so faithfully. The house he practised in is of considerable interest, as it was originally the home of the "Whitworth doctors," a dynasty of bone-setters whose fame was widespread, and whose patients included a future Archbishop of York and a member of the Royal Family; the first man of the line was a qualified medical man. Thomas Forbes was a man of fine physique and handsome appearance, quiet and courteous but friendly in manner. His later years were darkened by ill-health, which compelled his retirement from practice some

two years ago. He was J.P. for the County of Lancaster and for many years M.O.H. for Whitworth, and was a Fellow of the Society of Medical Officers of Health. Apart from these duties he took no active part in public affairs. He declined office in the local Division of the B.M.A., but was a very loyal member of the Association, and consistently upheld by example a high ideal of professional behaviour in his relations with his patients and colleagues. He was cremated at Rochdale on August 4. The service was attended by the members of the Whitworth Urban District Council and a large number of his old patients and professional colleagues. He is survived by his widow and two sons.

The following well-known medical men have died abroad: Dr. MAX BJORKSTEN, a famous Helsingfors epidemiologist, aged 75; Dr. JAKOB SZWACER, formerly director of the Czyston Hospital, Warsaw, aged 90; Prof. JOSÉ DA COSTA CRUZ, director of the Oswaldo Cruz Sanatorium, Rio de Janeiro; Dr. BRANSFORD LEWIS, emeritus professor of urology at St. Louis University School of Medicine, aged 78; Dr. JOHN TEMPLETON BOWEN, an eminent dermatologist of Boston, emeritus professor of dermatology at Harvard University, whose name has been given to a precancerous dermatitis, aged 84; Dr. SVUCEL W. BECKER, assistant professor of dermatology, University of Chicago, author of *Common Diseases of the Skin*, aged 47; Prof. W. A. JOLLY, a Zurich psychiatrist; and Dr. CHARLES WALLIS EDMUNDS, a leading member of the Council on Pharmacy and Chemistry of the American Medical Association and co-editor with Prof. J. A. Gunn of Oxford of *Cushny's Textbook of Pharmacology and Therapeutics*, aged 68.

Universities and Colleges

UNIVERSITY OF OXFORD

The Theodore Williams scholarship in anatomy, 1941-2, has been awarded to P. P. H. Schmidt, St. Catherine's Society.

UNIVERSITY OF LONDON

The headquarters of the University of London administrative staff has moved from Royal Holloway College, Englefield Green, Surrey, to Richmond College, Richmond, Surrey (telephone, Richmond 2301).

The title of Professor Emeritus of Physiology in the University has been conferred on Dr. Winifred C. Cullis on her retirement from the Sophia Jex-Blake Chair of Physiology at the London (Royal Free Hospital) School of Medicine for Women. Miss Esther M. Killick, M.Sc., M.B., Ch.B., has been appointed to succeed Prof. Cullis.

SOCIETY OF APOTHECARIES OF LONDON

At a meeting of the Court of Assistants of the Society of Apothecaries Sir Stanley Woodwork, M.D., F.R.C.P., was elected Master for the ensuing year, Prof. F. G. Parsons, D.Sc., F.R.C.S., Senior Warden, and Mr. V. Warren Low, F.R.C.S., Junior Warden.

The following candidates have passed in the subjects indicated:

SURGERY.—K. J. Adams, G. J. Ambrose, E. D. C. Davies, S. Fink, S. E. Gordon, S. Hashim, H. G. King, Pak So.

MEDICINE, PATHOLOGY, AND FORENSIC MEDICINE.—K. J. Adams, H. P. Anderson, B. Berman, E. D. C. Davies, M. C. Hannon, A. Hannun, J. H. C. Hill, D. W. Mayman, S. S. Zohar.

MIDWIFERY.—K. J. Adams, G. R. Boyes, E. D. C. Davies, S. Hashim, N. F. Murphy, T. W. Renton, B. E. O. Williams.

The diploma of the Society has been granted to K. J. Adams, H. P. Anderson, B. Berman, E. D. C. Davies, S. Fink, A. Hannun, S. Hashim, J. H. C. Hill, and D. W. Mayman.

The Services

HONORARY PHYSICIAN TO THE KING

Lieutenant-General Alexander Hood, C.B.E., late R.A.M.C., Director-General, Army Medical Services, has been appointed an Honorary Physician to the King, in succession to Lieutenant-General Sir William P. MacArthur, K.C.B., D.S.O., O.B.E., retired.

COLONEL COMMANDANT, R.A.M.C.

Major-General H. P. W. Barrow, C.B., C.M.G., D.S.O., O.B.E., retired pay, late R.A.M.C., has been appointed Colonel Commandant of the Corps, vice Major-General R. S. Hannay, C.B., C.M.G., D.S.O., retired pay, late R.A.M.C., who has attained the age limit for the appointment.

CASUALTIES IN THE MEDICAL SERVICES

AUSTRALIAN ARMY MEDICAL CORPS

Captain STEWART IRVINE WEIR, who was killed in action in Greece in April, was educated at the University of Melbourne, where he graduated M.B., B.S. in 1930. He became a Fellow of the Royal College of Surgeons of Edinburgh six years later. He had been a member of the British Medical Association since 1935. He leaves a widow and one daughter.

DEATHS IN THE SERVICES

Colonel ANTHONY HENRY WARING, D.S.O., late R.A.M.C., died at Maresfield on August 9, aged 69. He was born on November 28, 1871, and took the M.R.C.S., L.R.C.P.Lond. in 1895. Entering the Army as surgeon lieutenant in January, 1896, he became lieutenant-colonel in the long war promotion list of March 1, 1915, and colonel on October 15, 1916, was placed on half-pay on December 26, 1919, and retired on January 8, 1921. He served throughout the war of 1914-18 in France and Flanders, was mentioned in dispatches in the *London Gazette* of October 10, 1914, and May 20, 1917, and received the D.S.O. in 1917, and was also appointed Commander of the Portuguese Order of Avis. After his retirement he lived for many years at Antibes, in the Alpes Maritimes, France.

TUBERCULOSIS IN INDIA

To assist tuberculosis work in India a subcommittee of the Tuberculosis Association of India has issued a report on classification of pulmonary tuberculosis. The recommendations include taking into account the anatomical extent of the disease judged by both physical and x-ray examination, and the subdivision of patients into two groups, according to the history—"acute initial" and "chronic recrudescence." By the term acute initial is meant a case with acute onset, a course of illness more or less continuous, without healthy intervals, with a duration not exceeding two years. By chronic recrudescence is meant a case slowly developing with healthy intervals, and cases of the acute-initial group with a duration of illness of more than two years. The classification recognizes three stages according to anatomical extent, special regard being paid to cavitation and complications: and each stage is subdivided into A, B, and C according to the extent of systemic disturbance. Recommendations are also made in regard to classification of results of treatment at the time of discharge. This includes the term "arrested" (which in Great Britain cannot be applied until two years after a case has been pronounced quiescent). In the Indian classification both the terms "arrested" and "quiescent" require that no tubercle bacilli should have been found in the sputum for the last three months, and this implies that "before the sputum is declared negative it should have been examined on four separate days in each of three months, using the ordinary smear method." It is, however, strongly recommended that culture methods should be used when no tubercle bacilli are found by the smear method, and that in all reports from institutions it should be stated, when giving figures for positive or negative sputum examination, whether culture methods have been used. The report also contains four informative and very useful appendices on radiography of the lung, sputum examination for tubercle bacilli, blood examinations in tuberculous patients, and on the taking of temperature in tuberculous patients.

INFECTIOUS DISEASES AND VITAL
STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended August 9.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included), (b) London (administrative county), (c) Scotland, (d) Eire, (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (London included), (b) London (administrative county), (c) The 13 principal towns in Eire, (d) The 10 pri

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

* Includes paratyphoid A and B for Eire and Northern Ireland.

† Includes primary form in figures for England and Wales, London (administrative county), and Northern Ireland.

‡ Includes one case of pneumonia not otherwise notifiable.

§ Owing to evacuation schemes and other movements of population, birth and death rates for Northern Ireland can no longer be given.

EPIDEMIOLOGICAL NOTES

Infectious Diseases for the Week

Last week's decline in the prevalence of infectious diseases in England and Wales continued; the only exceptions to the general rule were those of poliomyelitis and typhoid fever, the notifications for which exceeded last week's figures by two and four respectively. The returns for the other diseases reached the lowest level of recent months, the number of cases of whooping-cough being the lowest for over six months, and of diphtheria the lowest for the past year; measles reached the lowest level for over eighteen months, and the notifications for cerebrospinal fever, dysentery, and pneumonia were fewer than they have been for almost a year. In Scotland scarlet fever and whooping-cough showed an increase of 11 and 25 cases respectively over the notifications for the preceding week.

Typhoid and Paratyphoid Fevers

The notifications of typhoid in England and Wales were 38, and were four in excess of the previous week's total. Eight of these cases were reported from Rhayader R.D., Radnorshire. The decrease in the number of cases of paratyphoid reported during the week was mainly due to the subsiding of the outbreaks in Cheshire and Lancashire, where 19 and 20 fewer cases were recorded than in the previous week. The incidence is still very high in Lancashire, which, with 76 cases (40 in Liverpool C.B.), contributed slightly over half of the total for the country. Cumberland with 12 cases has the second largest number of notifications, due to an outbreak in Carlisle C.B., 10 cases.

Dysentery

No further case has been reported from Leiston-cum-Sizewell, where the outbreak last week resulted in 37 notifications. The cases reported in England and Wales during the week were only one-third of the total in the preceding week. This large decrease brings the incidence of dysentery to the lowest level since last autumn. London with 10 cases and Lancaster with 8 accounted for almost half of the cases reported in the country. Forty-five cases, a decrease of 7, were notified in Scotland; 23 of these were recorded in Lanarkshire.

Acute Poliomyelitis

There were 30 cases of this disease notified during the week, an increase of two on last week's total. A fresh outbreak occurred in Hertford (Ware U.D.), with 5 cases. Other multiple cases were reported from Berkshire (Maidenhead M.B. 2, New Windsor M.B. 2, Cookham R.D. 2); Buckinghamshire (Slough M.B. 4, Eton R.D. 2); Lincolnshire (Lincoln C.B. 3). Two deaths have occurred in the Slough district. Five cases were recorded in Scotland.

Cerebrospinal Fever

The notifications of cerebrospinal fever in England and Wales were only three-quarters of the number recorded in the previous week, and were the lowest for almost a year, but the incidence remains at six to seven times the pre-war level. Of the 121 cases reported, slightly more than one-quarter were contributed by two counties, Lancashire 19 and Yorkshire, West Riding, 15. The number of cases reported in Scotland was 38 (Glasgow 12 cases), compared with 39 in the preceding week.

J. A. Tuta and E. F. Hess (*Amer. J. Obstet. Gynec.*, 1941, 42, 142), who record an illustrative case, state that up to 1937 168 cases of carcinoma of the female urethra were on record. Primary urethral carcinoma must be distinguished from secondary carcinoma arising in the labia majora or minora, vestibule, Bartholin's glands, clitoris, or vagina. Within the urethra the usual lesions are prolapse of the urethral mucosa, caruncle, fibroma, or sarcoma. The present case was that of a housewife aged 57, in whom the menopause had occurred eight years previously. The symptoms were general bleeding and pelvic pain, and a small red ulcerated mass was found involving the meatus. Death took place after about four months' illness. The necropsy showed that the entire length of the urethra was invaded by a tumour (squamous-cell carcinoma), and there were metastases in both lungs.

Medical News

A general meeting of the Tuberculosis Association will be held at 26, Portland Place, W., on Saturday, September 13. At 10.30 a.m. Dr. H. V. Morlock and Mr. P. R. Allison will present a paper on "Bronchial Obstruction as a Factor in Pulmonary Tuberculosis," and at 2.30 p.m. there will be a discussion on "Tuberculosis and the Examination of Recruits," to be opened by Dr. P. L. T. Bennett.

A series of five lectures on economic problems, to be given on successive Tuesdays in September, at each of which the speaker will be a member of the House of Commons, has been arranged by the Henry George School of Economics. Town planning will be discussed by Mr. Andrew Maclaren on September 9 and industrial health by Dr. H. B. Morgan on September 23. The lectures will be given at the school's premises, 13, Suffolk Street, Pall Mall, S.W.1, to which address applications for tickets (price 1s. for each lecture, season tickets 4s.) should be made.

The Ministry of Food wishes to emphasize that the directions on cartons containing national dried milk, which were drawn up with the advice of the Ministry of Health, are of a general nature only. They should not be considered suitable for every infant, but should be modified at the discretion of the medical adviser. National dried milk is not a humanized food. It is manufactured by the roller process in two varieties: a full-cream powder with a standard fat content of 26% to 27%, but without any added iron and other ingredient, and with a calorie value of 18 to 19 to one fluid ounce of reconstituted milk; and a half-cream powder with a standard fat content of 16.5%, giving a calorie value of 16 to an ounce.

The Ministry of Health has circularized local authorities (Circular 2455) on the need for co-ordinating the arrangements made by industrial concerns in their area for the treatment of air-raid casualties and for disposal of the dead with those made by the authorities themselves. To this end industries are being asked where possible to allow the local medical officer of health to visit their premises to see the arrangements they have made, when he will be able to judge what help, if any, they may need.

Preliminary arrangements for Hospitals Day, to be held on Tuesday, October 7, are now being made by the London Hospitals Street Collections Central Committee. It is hoped to improve on the record collection made in May, when London's hospitals collected over £10,000 more than they had done before on any previous flag day. Suggestions and offers of service will be gratefully welcomed by the chairman, Lord Luke, at the headquarters, 36, Kingsway, W.C.2.

The August issue of *Industrial Welfare and Personnel Management*, the journal of the Industrial Welfare Society (14, Hobart Place, S.W.1), contains an article on relations between doctors and industry by Dr. W. D. Jenkins, medical officer, South Metropolitan Gas Company, Ltd., whose thesis is that (a) a part-time medical service is essential for the bulk of the industrial undertakings in the country; (b) this service must be staffed by general practitioners; (c) the lack of knowledge of industry and industrial conditions among doctors is due to their early training and the lack of appreciation by employers of the need for encouraging doctors to be interested in industrial conditions; (d) any difficulties which exist can easily be overcome by good will; (e) such services are productive only of good results and are an economic gain. The recently developed miniature radiography for detection of tuberculosis is described in an article on methods of mass radiography by Dr. A. S. Hall, tuberculosis officer of the Middlesex County Council, who points out that until there is a positive demand for the apparatus it will not be manufactured.

The Kober Medal of the Association of American Physicians was recently presented to Dr. William de B. MacNider, research professor of pharmacology at the University of North Carolina.

The 26th annual session of the American College of Physicians will be held at St. Paul, Minnesota, from April 20 to 24, 1942, under the presidency of Dr. Roger I. Lee.

In consequence of his appointment as Secretary of State for Scotland, Mr. Thomas Johnston has resigned membership of the Nuffield Provincial Hospitals Trust, and other vacancies have been caused by death. Lord Balfour of Burleigh, chairman of the Medical Research Council, Lord Wigram, Mr. Tom Williams, M.P., Sir Bernard Docker, and Mr. D. Lindsay Keir, vice-chancellor of Queen's University, Belfast, have accepted Lord Nuffield's invitation to become trustees.

Professors D. Keilin, F.R.S., and C. R. Harington, F.R.S., have been appointed members of the Agricultural Research Council.

Prof. C. Lovatt Evans, F.R.S., has been elected a foreign member of the Royal Physiographical Society of Lund, Sweden.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, W.C.1.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated.

Authors desiring REPRINTS of their articles must communicate with the Secretary, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors over-seas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

ADVERTISEMENTS should be addressed to the Advertisement Manager (hours 9 a.m. to 5 p.m.). Orders for copies of the *Journal* and subscriptions should be addressed to the Secretary.

TELEPHONE No.—B.M.A. and B.M.J.: EUSTON 2111.

TELEGRAPHIC ADDRESSES—EDITOR, *Aitiology Westcent, London*; SECRETARY, *Medisecra Westcent, London*.

B.M.A. SCOTTISH OFFICE: 7, Drumsheugh Gardens, Edinburgh.

QUERIES AND ANSWERS

"Cocktail" Burn

Dr. IAN F. S. MACKAY writes: Among the "casualties" at a recent Home Guard exercise was one that had received a burn from a "Molotov cocktail." This contains yellow phosphorus in solution. What is the first-aid treatment that you would advise?

Symptoms after Mercurochrome Treatment of Impetigo

Dr. NOEL C. BLEASDALE (Liverpool) writes: I have recently been treating a number of cases of impetigo contagiosa of varying degrees of severity by starch poultices in order to loosen the crusts, following which I have applied 2% solution of mercurochrome to the lesions. This treatment has proved very successful in the majority of cases, the sepsis associated with the condition clearing up very rapidly. In two cases, however, of impetigo of the back of the head and neck there was a temperature of 101° F. and relaxed stools three days after the application of mercurochrome, and in one there was vomiting on one or two occasions. I am wondering whether these symptoms could be due to the mercurochrome, but have not been able to find any records of such in the literature. Perhaps some of my colleagues will be able to clarify this point for me.

Income Tax

Payment of Interest

M. H. is paying interest on a private loan in lieu of bank interest paid in former years.

* Interest paid to a bank is an allowable deduction by statute, but interest paid to a private person, however, cannot be deducted. The reason is that in the latter case the payer is entitled to deduct tax from the interest at the time of payment and receives the allowance in that way. In other words, the fact that he cannot deduct the interest in calculating his own liability is the means by which he passes on to the Revenue the tax he is entitled to keep back when paying interest.

S. W. C. is paying interest to an insurance company instead of to a bank, as formerly.

* S. W. C.'s inquiry is similar to that of M. H., to whom a reply is given above.

Personal Allowances

J. M. has had tax deducted from military pay at standard rate without any deduction being made for "personal" allowances.

* * The note which is rubber-stamped on the notice accompanying J. M.'s letter states that the personal allowances, and presumably the benefit of applying the lower rate of tax to one "slice" of income, have been applied to some other source of income—possibly to a share he may retain in the profits of a practice. If that note is correct no further allowance is due; if it is incorrect the matter should be taken up at once with the War Office income-tax authorities.

Continuance of Liability for Rent

"LEASEHOLDER'S" practice ceased on his entering war work under the Emergency Scheme, but he remains liable for rent in respect of the premises at which his practice was formerly carried on. Can he claim an allowance in respect of the payments of rent?

* * If his practice cannot be regarded as having been continued we see no legal ground on which a claim could be based. If, however, some evidence can be put forward—e.g., that the plate remains on the premises and that some other practitioner is available to deal with clients—then we think that it might be possible to persuade the authorities to regard the practice as still continuing, and in that event a claim might be made under the Income Tax Act, 1918, Section 34, in respect of the loss occasioned by payment of the rent. (If an appeal *ad misericordiam* should meet with success we should be glad to hear of it.)

Car Used for Official Purposes

P. K. is employed by one of the Ministries, and receives an allowance for the use of his car which may cover running costs but not depreciation. Can he claim an allowance?

* * He is assessable under Schedule E and is entitled only to expenses (including depreciation) incurred "wholly, exclusively, and necessarily in the performance of his duties." It may be that he uses a car of greater cost or horse-power, or for a greater mileage, than is "necessary" for his official use, but in any case he would find it very difficult to persuade the Income Tax Commissioners that the cash allowance he receives from the Ministry is inadequate on the very strict and limited basis indicated above.

LETTERS, NOTES, ETC.**Systemic Factors in Wound Healing**

Dr. G. ARBOUR STEPHENS (Swansea) writes: Dr. Grant Waugh's article on the systemic factors influencing wound healing (August 16, p. 236) is of importance not only because it is sound in doctrine but because it tends to emphasize the importance of the part played by these factors. In July, 1906, I showed that wounds or ulcers of the leg are helped to heal by the internal administration of calcium iodide, which has the effect of raising the pH. Dr. Waugh holds that a lowered pH of tissues, especially near the wound, is essential for good healing. Were that so, large quantities of beef and beer ought to be just the things to consume! The value of vegetables lies in their basic tendencies to raise the pH, while the cereals and carbohydrates make the tissues more acid. Balanced diets are composed of basic vegetables and acid meats, of basic milk and acid breads. The children of the poor live on acid bread, and as a result are the first to fall victims of all epidemics. It was for this reason I got the Swansea education authority to be the first to give milk to school children and set an example to the rest of the country. Metal burns or wounds heal quickly when cleaned by petrol or benzol, which is able to wash away the surface fatty substances to which the germs and half-burnt toxic tissues adhere. After the petrol has evaporated it leaves a clean and a dry wound—the two great essentials for healing. In a large local spelter works metal burns kept the workers away for six to eight weeks, but since petrol treatment was introduced loss of work is nowadays exceptional.

Treatment of Impetigo

Dr. MAURICE E. J. PACKER (Bristol) writes: With reference to the treatment of impetigo (August 16, p. 225) I did a considerable amount of experimental work on this at a school clinic. My experience suggested that the best treatment is to tear off small pieces of cotton-wool just the sizes of the sores, damp them with lotio cupro-zinica, and cover generously with elastic adhesive plaster. This is left on for a week, at the end of which time the big majority have healed; if not, repeat. Some cases proved resistant, but these were exceptional. This method is especially valuable at clinics, as it saves children attending every day. Also, if every sore is covered the danger of infection is reduced to a minimum, and attendance at school while being treated might be considered.

Cardiac Arrest during Anaesthesia

Dr. JOHN ARMSTRONG (London, W.C.2) writes: Mr. Hamilton Bailey (August 16, p. 243) must be unfortunate in his anaesthetists. In my early days in Glasgow Royal Infirmary I administered chloroform over 2,000 times with no deaths, some of the operations lasting to three hours.

Adhesive Bandages: Avoiding Painful Removal

Captain M. H. L. DESMARAIS, R.A.M.C., writes: Much discomfort and pain is experienced by the patient when elastoplast bandage is removed. The bandage sticks to the hairs and also causes some irritation of the skin. On the suggestion of my orderly the bandage is applied in reverse in cases where only support is required, and the sticky surface of the bandage is then powdered with French chalk.

Epistaxis

Dr. R. GAINSBOROUGH (Uckfield) writes: The control of epistaxis by the ordinary method of plugging is a painful process both in its application and in the removal of the plug. I was called recently to a case where a serious loss had occurred from recurrent haemorrhages. I was unable to plug on account of the patient's sensitiveness and previous experience, and decided to use a stream of hot air to accelerate clot formation. I found this at once successful, and as the patient had haemorrhage on two subsequent days he controlled it himself immediately by applying this method. The stream of hot air was obtained from a domestic hair-dryer. I do not know if this remedy has been used before, but I found it extremely effective.

Chloroform in the 'Eighties

Dr. J. N. MARSHALL (Rothesay) writes: I have been following with interest the correspondence about anaesthetics in your columns, and have been moved to add a short note of my own experience. I would like to confirm what Dr. J. T. MacLachlan—a countryman of my own from the north of Scotland, and evidently of about the same vintage as myself—said (July 5, p. 19) about the use of chloroform in the Western Infirmary, Glasgow, and the absence of fatalities in its use in the early eighties of last century. In 1882 I was house-surgeon with Hector Cameron, the other visiting surgeons being George Macleod, George Buchanan, and Alexander Patterson. As a rule the house-surgeons administered chloroform, and the senior students were carefully instructed in its use. So far as I know there were no fatalities at that time. Macleod was then at the Royal Infirmary, Glasgow, and he also used chloroform. Later I often gave it for him in private practice. During the next ten years I was engaged largely in country practice and used chloroform in midwifery, in minor surgery, and in the many exigencies of general practice, sometimes alone, sometimes with assistance. From 1897 I had the inestimable privilege of hospital practice in the Cottage Hospital at Rothesay, a similar privilege which all country doctors should have. From that date until 1934, when I retired from general practice, I had chloroform administered, with ether in the background, by one or other of my colleagues in the hospital with only one death, though undoubtedly there were quite a number of "near misses" of fatality which caused anxious moments. A rough though conservative estimate of the number of chloroform administrations in the above series is 3,500. Chloroform is undoubtedly a killer drug, but used with skill and care it is a friend in need to the general practitioner, and all students should be trained in its use or in the use of some other anaesthetic.

A Diabetic Chart

Dr. H. CECIL BARLOW writes: We have recently introduced into the wards at the Lincoln County Hospital a type of chart for diabetic cases, and find it very useful. It is simple to keep, it affords at a glance the progress of the case, it is a fairly complete record which can be completed by a few notes on the case sheet, and being the same size as the ordinary temperature chart can be bound up with the records in the case books. It is printed by Messrs. Heyworth and Sons, Lincoln.

Stains for Microscopical Work

British Drug Houses Ltd. have recently issued a forty-page booklet on their standard stains for microscopical work. In the first part details are given of the different routine methods of staining bacteria and preparing microscopical sections and of staining cells. This is followed by a price list of B.D.H. microscopical stains. The booklet can be obtained free of charge on application to the firm at Graham Street, City Road, London, N.1.

BRITISH MEDICAL JOURNAL

LONDON SATURDAY SEPTEMBER 13 1941

A SURVEY OF ONE HUNDRED CASES OF WAR NEUROSES*

81

JOHN D. SUTHERLAND, Ph.D., M.B., D.P.M.

Assistant Physician, Emergency Hospital Service, Department of Health for Scotland; formerly Lecturer in Psychology, University of Edinburgh

In this report some observations are presented on the previous history, treatment, and results of treatment of 100 men admitted to an E.M.S. hospital suffering from psychoneurotic states occurring during or after exposure to combatant action. No commissioned officers are included in the group.

A number of workers in this field have been interested in the type of person who develops a psychoneurosis under the strain of active service. Besides having important implications regarding the prognosis and treatment of these cases, a study of the prominent features previous to breakdown is of the utmost value in the detection of possible psychoneurotics. Though as yet no schema has emerged, their detection by some form of psychiatric examination at the time of recruitment has engaged the attention of many psychiatrists, and our survey has led us to make some suggestions towards this end. There is little doubt that the psychoneurotic can be valuable in military service as in other spheres, yet often his greater liability to panic is a constant menace to the morale of any fighting unit. More than one of our patients was acutely distressed by his effect on other men. We would not for a moment suggest that all psychoneurotics should be eliminated from the Forces, but when a strong predisposition to nervous breakdown is detected it would appear that the type of service into which the individual is to be sent should receive proper consideration.

Since the present war began sharply divergent views have been expressed on the methods of treatment of these illnesses and different results quoted. These variations appear to be due largely to the orientation of the particular workers, according to whether the symptom, or the dynamic disturbance in the personality underlying the production of the symptom, was the focus of interest—i.e., whether a short-term or a long-term policy was adopted. Which of these approaches is the more useful is a question on which our observations leave us in no doubt. The "war neuroses" are essentially the *neuroses in war*, and in my opinion the treatment and disposal of these cases can be based only on this fundamental standpoint.

Nature of the Group

It should be noted at the outset that the cases here considered must be regarded as the more serious instances of this type of illness. Most of these patients had been in other hospitals before coming under our care: on the average each man had been two weeks in hospital, followed by one week of sick leave. Thus the selective

nature of the group precludes conclusions about the incidence of certain factors in general.

Ranks.—The distribution in ranks was as follows:

P. Sgt.-major	1	Corporals	7
C.O.M.S.	1	L/corporals	7
Staff sergeant	1	Other ranks	7
Sergeants	9		

This represents a proportion of 23% N.C.O.s—roughly the proportion of N.C.O.s to other ranks in the Army as a whole. (It would be unwise to stress statistical observations based on such a small number of cases; therefore many of the following remarks should be considered with this limitation in mind.)

The preponderance of sergeants is probably connected with many factors besides possibly greater strain. (This preponderance has been found to exist in a subsequent group of similar cases.) Their greater average age (36 years) and the fact that some were given this rank because of their technical experience rather than any special personal qualities would doubtless be contributory factors.

Age and Family Connexions.—The average age of the whole group was 29 years 10 months, the age distribution being:

20-24	38	40-44	3
25-29	21	45-49	4
30-34	15	50-54	2
35-39	17		

Fifty-eight men were married, 39 of these having children.

Motives for joining Army, and Attitude to Service.—The recruitment categories form an approach to the question of motives in joining, and of the attitude to the Services. These were:

Regular Army	14	Territorials	31
Regular Reserve	12	Volunteers	25
Supplementary Reserve	6	Conscripts	12

Perhaps the most striking feature is the low incidence of conscripts. It might be expected that conscripts would form a high proportion of breakdowns as compared with volunteers, though there are, of course, factors opposing such a tendency. For example, age might offset breakdown, as the younger men are not so likely to be harassed by family ties, etc., and are correspondingly readier to respond emotionally with the "joy of battle." Again, the most common type of neurosis occurring in the younger conscripts may yield more readily to treatment, so that only the more serious cases reach us. Certainly a third of the conscripts felt definitely unhappy from the start of their service, and would not have volunteered; 6 of them had a bad early history.

Of the 14 soldiers of the Regular Army 5 had ; up impulsively to escape an unhappy situation

* A paper read to the Scottish Branch of the British Psychological Society on May 24, 1941.

regretted the step afterwards, and looked forward to the time when they would be freed from what they felt to be an irksome bondage. The Territorial and volunteer groups included a good proportion of highly conscientious men impelled to serve by a strong sense of duty despite their anxious tendencies. A few of the Territorials nevertheless showed unsatisfactory motives—e.g., to avoid conscription, to get social outlets, enlisting under what was felt to be pressure from employers or to ensure being in non-combatant service. The majority of this group had had some years of service, the median period being four years, and it is of interest that the 7 men who joined in the year preceding the outbreak of war had very bad histories of psychoneurotic symptoms. Their enlistment was more in the nature of an attempt to deal with rising anxieties than of mature consideration about duty. Among the volunteers also were several men whose enlistment was occasioned by unpropitious elements. Thus 10 joined primarily to get more money than the unemployment allowance. Two joined impulsively for no very good conscious reason, while another pair volunteered for non-combatant service. There were 7 who joined for special engineering work: these men, who were older than the others, did not expect to be engaged in battle. One man's reason for enlisting was to avoid arrest.

Altogether 37 men joined the Services with an inadequate attitude and were thus under a strain from the start. They showed poor appreciation of their roles in a time of national danger, and were subsequently too much concerned with their personal problems for the larger issues to govern their conduct. The situation of those men who, aware of their psychological limitations, volunteered for specialized work and later became involved in combatant action was an unfortunate one. The Supplementary Reservists suffered in this fashion. Mostly older men, they enrolled willingly for specialized branches, but found the unexpected strain of battle too heavy. Evidently the ease with which this situation may nowadays arise would make advisable a psychiatric scrutiny of such men before detailing them for service abroad.

Physical Condition.—Practically none of the group had any signs of systemic disease. Three with positive Wassermann reactions were found, one being suspected clinically and the others discovered in routine testing. On the average, physique was good, only 6 men being of poor development. Two of the latter were thought to be possible cases of pulmonary tuberculosis, but radiological examination was negative.

Intelligence.—Owing to pressure of time it was not possible to measure intelligence satisfactorily. Twenty men reported having been backward at school, and probably most of these were borderline defectives. When the matrix test (Raven, 1939) was given to 45 unselected cases in the group a mean mental age of 12 years was obtained. On later admissions of this type the Herring revision of the Binet-Simon tests gave an average mental age of almost 14 years.

Previous History and Prediction

Eighty of the hundred cases admitted having traits indicating previous emotional instability. They could be divided into the following groups:

Group 1.—In this group were 36 men who had a disturbance amounting to a definite and easily recognizable psychoneurotic condition before joining the Army, so that the state which developed after traumatic experience was merely an aggravation of one already well established. Included in this group are those men who had had previous episodic illnesses—e.g., previous spells of depression or transient hysterical symptoms. It is safe to say that none of this group should have been exposed to combatant action, so great was the likelihood of breakdown in view

of their previous history, and at best only a small proportion should have been admitted to any kind of service with the Forces.

Group 2.—This group comprised 33 men with a characterization pointing to a latent psychoneurotic condition or with a degree of temperamental instability, though without gross symptoms. It contained the over-anxious and over-conscientious types, the poorly adapted socially, and a number of weak personalities who had never made much of a success in any occupation. It is more difficult to forecast the behaviour of men of this type under strain. Most of them were capable of service of some kind, and probably a fair proportion would have remained well enough in home service.

Group 3.—This consisted of 11 men whose only striking characteristic was that they had always been restless. They frequently changed their jobs, yet worked with fair efficiency so that they were seldom unemployed. They, for the most part, were good soldiers until they broke down (there were a few regular soldiers among them), but showed temperamental instability with a marked lack of doggedness.

Group 4.—This comprised 20 men whose previous history was good and whose breakdown would not have been expected. There was a definite tendency for them to fall into two sub-groups of different age levels, the first consisting of men over 35 who found the pace of events rather fast, and the second of men under 25, in whom breakdown was mostly of a milder character.

A list of some of the specific symptoms and their frequency provides an instructive approach to the kind of factor to be inquired into in any brief psychiatric examination such as might be made by medical officers as a preliminary filter for the separation of these cases.

Previous Symptoms and Traits

		Previous	hysterical	sym-
Anxious over being aggressive	54	toms or fits	1	
"Nervousness"	41	Domestic strife or worry ..	1	
Frequent change of type of work	27	Nail-biting	1	
Phobias	24	Frequent blushing	1	
Anxiety dreams and night-mares	17	Stammering	1	
Shyness	17	Stealing and persistent truancy from school ..	1	
Solitariness	13	Tics	1	
Mild depressive spells	12	Previous serious accidents ..	1	
Anxiety attacks	11	Previous serious accidents followed by emotional disturbance	4	
Avoidance of females	9			
Enuresis	8			

Because a certain degree of rapport is usually necessary to elicit a full symptom-picture in the psychoneurotic examination of all men by psychiatrists is not at present feasible because of the time it would take. Nevertheless it seems to me that a useful and practicable psychiatric selection could be made in the first place by referring to the psychiatrist those patients who admit or show general "nervousness" at initial medical examinations. More often than not the anxiety manifestations in these cases during routine medical examination would make the admission unnecessary. (From experience of many other patients in this hospital who were not exposed to combatant action a useful selection could have been made in this way. As would be expected, the previous history is even more striking in these cases.) Whenever specific symptoms were found the men could be referred to the psychiatrist for fuller investigation and opinion.

Family History.—Information about nervousness in their families was obtained from the men themselves, and is thus apt to be inaccurate. However, from a description of specific behaviour in the relatives mentioned it could usually be decided whether or not the individual was abnormal enough to be recorded as such. Fifty-three men reported the presence of emotional instability either in parents or in siblings, as follows:

Both parents nervous	8	Mother nervous	11
Father nervous	17	Siblings nervous	12

In 15 of the cases with parental abnormality there was also instability in a sibling. Doubtless family history in the

psychoneuroses is of uncertain value unless information from other sources is obtained. Moreover, its significance lies in its association with the previous history of the individual rather than in an independent contribution. The importance of abnormal early environment is illustrated by these facts. In 16 homes there was serious drunkenness or parental strife, while 6 patients acquired a step-parent in early childhood, and 3 were "only children." Nine men lost their fathers by enemy action in the last war, 6 of this group admitting no specific nervous symptoms in their previous histories. Another man was illegitimate and was brought up in trying circumstances.

Precipitating Factor and Onset of Symptoms

As is well known, early in the last war the strongly materialistic standpoint of general medicine inclined to the view that the war neuroses arose from some form of *commotio cerebri*, a view gradually abandoned under the persistent barrage of facts. With our patients it was difficult to ascertain the extent of shock or whether concussion had been present or not. Many reported amnesia for varying periods, but the comparatively easy recovery of memory made it almost certain that there had been no true concussion. Further, most of these patients with amnesia recalled clearly the particular stimulus causing the loss of memory—i.e., they showed no retrograde amnesia, as would be expected in true concussion. There was 1 case of cranial injury and only 3 cases of apparently true concussion so far as previous reports show. Seventeen men had been subjected to physical violence by blast, though few of these lost consciousness. Ten others were wounded in the body—wounds mostly of a superficial character: and in those cases in which deeper structures were involved healing was rapid. Bombing of ships, with immersion in the sea, was the traumatic experience in 7 cases. For several men the critical experience was the loss of friends severely wounded beside them, while others were especially upset by the harrowing scenes of women and children being machine-gunned and bombed.

The onset of symptoms in most cases occurred during battle, though a quarter of the patients developed marked symptoms after return to this country. For the most part these latter were men who had had mild anxiety symptoms for a period, the depression which supervened being the cause of their reporting sick. A few conversion symptoms, however, also appeared after a latent period.

The majority admitted readily that their illness began as the climax to a rising feeling of fear and strain under the process of battle. With the increase of their anxiety they often became more and more afraid of loss of control, until finally some special circumstance brought about disintegration. The fundamental factors in the breakdown were the subjective significance of the trauma plus the particular psychological make-up of the individual. Thus different traumata evoked similar states, and, conversely, the same trauma gave rise to different disturbances—e.g., a conversion hysteria or a depression. As would be expected, where the predisposition seemed less marked the traumatic experience was more severe, and vice versa, an illustration of this inverse relation being given by these figures:

Traumatic Experience	30 Cases of Bad Previous History	30 Cases of Better Previous History
Fear and strain	18	6
Blast	4	11
Wounded	2	6
Death of friends	2	3
Aerial attack on ship	4	4

Symptomatology

It has to be borne in mind that the cases described were not investigated until, on the average, several weeks after the start of the illness. Anxiety manifestations were by far the commonest complaints, the symptoms in order of frequency being:

Feelings of anxiety with trembling and jumpiness	66	Panic attacks	15
Sleeplessness	47	Suicidal:	
Headache	43	Actively	5
Unsociability	37	Passively	7
Anxiety dreams	35	Hysterical conversions:	
Depression	33	Leg	16
Irritability	30	Arm	2
Preoccupation	27	Visual	6
Amnesia for whole or part of traumatic experience	25	Auditory	3
Giddiness	23	Tics	4
Effort syndrome	21	Voice	3
Spontaneous emotional outbursts	19	Stuttering	6
		Enuresis	3

There were three main groups—the anxious, the depressed, and the hysterical. Much overlap existed, yet the dominant affective disturbance usually made it possible to place a man in one of these classes. Typically, the anxiety cases showed tremors and jumpiness, especially to noises, disturbed sleep, and anxiety dreams involving war imagery. They also had frequent headaches, restlessness, and occasional giddiness. By the time the men reached this hospital the exhaustion described by many writers in the early stages of war neuroses must have been overcome.

We have included the effort syndrome group in the anxiety neuroses, as without exception they showed anxiety symptoms at some stage. In a few cases it was interesting to watch the development of effort syndrome accompanied by a corresponding diminution in the experience of anxiety—a process which could be likened to the development of a conversion symptom. Panic attacks occurred in about a quarter of the anxiety cases, usually precipitated by a passing aeroplane, train, or motor-car. Less common in this group were gastro-intestinal disturbances. 2 patients having diarrhoea and 3 vomiting and gastric pain. The 3 with positive Wassermann reactions were found in the anxiety group, but the psychological picture of these men differed in no way from that of the other cases.

As mentioned, the groups were not clearly demarcated. Thus many of the anxiety group had conversion symptoms, and 20 of them showed a well-marked depressive trend. Depression was the dominant feature in 13 men. These cases did not show the characteristic depression of melancholia, though in 2 of them a typical psychotic depressive picture with self-reproach eventually developed. The common depression appeared to be chiefly a state of futility and a withdrawal of interest from the outside world, with a consequent irritability towards its incursions. Five of the depressed cases were suicidal. Suicidal impulses, however, were not confined to the depressives, as some of the men with anxiety states reported transient suicidal impulses, mainly of a passive character, shortly after the onset of the illness. Several of those showing depression stated that if forced to return to battle they would rather commit suicide than experience again what they had undergone. The depressed group showed to a conspicuous degree the importance of constitutional and hereditary factors. Before a review of the group as a whole was made my colleagues and I were given the impression that the depressed patients tended to be the older men, especially those with families. In fact, the age and the proportion of married men with children in this group were almost identical with those in the group as a whole. There was a previous history of pronounced emotional disturb-

ance, however, in 90% of this group, and a positive family history was reported in 70%.

Hysterical manifestations occurred for the most part in the leg (16 cases). Of 4 men with tics 3 had had the symptom in earlier years. The cases designated hysteria were those in which "conversion" of the affective disturbance to a somatic disorder was superficially complete—i.e., they exhibited the paralysed function but denied any emotional upset. Their attitude typically was: "If only my leg were right I would be quite fit."

Although all patients were sent as psychoneurotics, it was found that a few were psychotic. Two proved to be hallucinating schizophrenics, while 2 depressed cases eventually revealed a typical melancholia. A few other depressed patients became so strongly suicidal that removal to a hospital for psychotics had to be recommended despite the fact that a true melancholia was not present. Mixed reactions occasionally made classification a matter of doubt, especially in the anxious-depressed cases, and since 7 of the depressed group had a history of recurrent attacks of depression they were more accurately labelled "cyclothymic."

A consideration of the total personality would have led to a different label being given to many of the cases. The long-standing histories of maladaptation, the emotional detachment of many to the revival of traumatic experiences (even after administration of intravenous anaesthetics such as pentothal or cyclonal), and, above all, the extent to which their emotional integration depended on their proximity to wives and mothers, would have made "psychopathic personality," in particular the schizoid type, more accurately descriptive of a large proportion of the cases. Exemplifying the underlying psychopathic trend in many were frequent breaches of regulations. To anyone accustomed to the over-conscientious conduct of anxiety neurotics in peacetime, the difference in behaviour of these men was most striking even when allowance was made for the compulsive character of many of the misdemeanours.

The following list shows the distribution in the symptom groups.

Anxiety neurosis ..	42	Psychopathic personality	
Anxiety neurosis with hysterical conversions ..	20	(temperamental instability)	8
Conversion hysteria ..	14	Schizophrenia	2
Depression and cyclothymia	13	Traumatic diathesis after cranial injury ..	1

Intelligence, as tested in a proportion of the whole group, was of the same level in the different symptomatic groups except in the case of the conversion hysterics, whose average intelligence was about two years lower than that of the other groups.

Treatment

There is no doubt that many of the unfortunate disputes over the treatment of war neuroses have arisen from the publication of so-called "cures" without adequate follow-up data. As every psychotherapist knows, certain psychoneurotic symptoms can be removed rapidly by a wide variety of methods, but the rapidity of removal by so-called "simple" procedures would appear to be closely correlated with liability to recurrence of the same or other disturbances. For example, the men with conversion hysteria had their symptoms alleviated by persuasion, suggestion, and, in a few uncooperative or unresponsive cases, by one or two cardiazol convulsions. But when the question of returning to units arose many of these symptoms developed afresh. Few of our anxiety cases showed any improvement with such "simple" procedures, even when these were combined with sedation. (It must be mentioned again that most of our cases had already resisted "simple" treatment.) Abreaction was essential with most of the anxious

patients. Often the reluctance of the patient to revive his nightmarish experiences was overcome by very slight emotional release, which produced far better results on sleeplessness than did sedatives. Sometimes the traumatic experience was scarcely verbalized, yet when brought to the threshold of articulation sufficient affective discharge appeared to take place (e.g., through all the bodily expressions of acute anxiety) for an appreciable improvement to be felt. Intravenous anaesthetics were most useful where amnesic gaps could not be filled in unaided. Nevertheless the end-product of abreactive treatment was for the most part a highly anxious individual. Usually a diffusely anxious state became canalized into phobias of certain situations, mostly connected with the noise of aircraft or explosions, with a feeling of comparative ease between the phobic experiences. Where the residual phobic anxiety was too disturbing more radical treatment, involving deeper childhood anxieties, had usually to be undertaken. Twenty-five of the cases required treatment of this more extensive character, lasting two to three months, in order to secure enough freedom from symptoms for discharge from hospital.

The depressed group tended to recover under reassurance and sedatives, and in a few slower cases one or two convulsions led to improvement.

Psychopathology

As contrasted with suggestion and reassurance, any form of analytic treatment, however slight, gives some degree of insight into the aetiology of the illness. Obviously, on account of time requirements, no case could be treated along orthodox psycho-analytic lines, so that the psychopathological factors studied tended to be those at superficial levels.

At a conscious level the common disturbing factors were fear of death and an impotent rage against what were felt to be overwhelming odds. This rage was often excited to a paralysing degree by the slaughter of women and children or by the loss of friends. On those men whose fathers had died in the last war the fear of death probably had a more profound effect. It could also be said to involve deep levels in all the cases—as though it derived from a childhood fear of attack by fantastically powerful "bogymen." The feeling of helplessness in face of danger was made more acute by the insecurity arising from the peculiar features of mechanized warfare.

The outstanding feature of the deeper psychology appeared to be a basically insecure attitude towards the outside world. This attitude was manifested in many ways, particularly in the excessive dependence upon those figures with whom security was felt—namely, their families. It was as though these men had always unconsciously dreaded the assertion of their independence as a dangerous aggressive process. To attempt it was to incur the wrath of parents, whose vengeful attitude was a magnified image of their own feelings. Rather than risk this talionic vengeance they appeared unconsciously to adopt a role of bondage to them, so that the devotion was as much a deep compulsion as a virtue. Their dependence was made conspicuous by repeated requests to be allowed to return home, usually with the explanation that a short spell there would make a great improvement despite the fact that most of them had already had sick leave. After air raids on their home areas the compulsive nature of these wishes could sometimes be pointed out successfully—e.g., when the men admitted that at home they would be far more anxious than their relatives. In the depressed cases there seemed to be a doubt even of this security with families, the result being that these men acted as though compelled to isolate themselves. They were often unable to write

home, or if they went home they were unsociable and irritable; a few lost all sexual desire in this phase.

There can be no minimizing the importance of this separation anxiety, which in our opinion is a psychopathological factor probably not enough appreciated in general on account of its being concealed in cases undergoing psychotherapy in peacetime—that is, amidst their emotional props. Moreover, it is almost certainly one of the greatest factors governing the pronounced negative therapeutic reaction of these cases compared with the neuroses of peacetime. It was the rule to have treatment accepted gratefully, with relief of symptoms, until the threat of continuing the separation by a return to duty became a menace to the patient. Then the desire to leave the Service became explicit. It could not be said, however, that malingering entered into this attitude, which was based on the powerful dread of isolation from love and security. Interpretation of this situation usually improved the symptom-picture up to a point, but to change the underlying weakness of the dependent ego was too great a task for any short period of treatment, even in favourable cases.

In those men with recurrent anxiety dreams the infantile character of the anxiety was often perceptible. For instance, though modelled on battle scenes, the dreams might be located near their childhood homes, or the manner in which the individual was the unique object of persecution by the enemy suggested childhood nightmares in which the ogre or witch was replaced by the aeroplane. Where one outstanding incident had occurred, such as shipwreck, the dream was usually a more persistent repetition of the trauma; yet soon after abreactive treatment began, perhaps with superficial explanations, there was a tendency for infantile dreads to become more transparent.

As already mentioned, the depressed cases showed a state of resignation and withdrawal plus a sense of futility rather than a feeling of loss or sadness; and they revealed a greater incidence of predisposing signs and family instability.

The factors determining the choice of illness form too large a problem for discussion here. It might be noted, however, that in the conversion hysterics there was a lower average intelligence, while wounds and blast as traumatic experiences were slightly more common. (Because of the small numbers this difference was of uncertain significance.) A general feature of the hysterical group was a strong latent feminine trend; and, indeed, deep identification with family figures, especially parents, could be discerned in several cases throughout the series—for example, in the assumption of symptoms from which a parent at one time suffered.

Results

Before describing the results of treatment some general considerations will not be out of place. If therapy aims merely at getting the patient into approximately his state before breakdown a fair percentage of "cures" might be obtained. But with simple suggestive or sedative treatment the patient is left as prone to further breakdown as before. On the other hand, with any form of analytic treatment (including abreaction) it is assumed that some lessening of the tendency to subsequent breakdown should result. Our experience has been that the treatment of patients with a view to elucidating causal factors, even when the symptom-disturbance appeared slight, showed in the large majority of cases that the personalities were structurally so weak and unstable that return to further combatant service was quite out of the question. It is possible that the circumstances in which treatment was carried out might have had a bearing on the adoption of this view. All our patients had been far removed from

the neighbourhood of battle, with a consequent heightening of the dread of return. In the last war treatment in France, with continuity of the military atmosphere and the absence of such a retreat, perhaps enabled a larger fraction of patients to return to duty. It is far more likely, however, that the greater understanding and knowledge of the psychoneuroses to-day would not have agreed with such a course, as, indeed, actual results proved by 1918.

On account of the low percentage of cures the question arises: what is the value of psychotherapeutic units in war? The answer to this may be given by referring to analogous problems in other fields of medicine. For instance, what percentage of dyspeptics, cardiac weaknesses, or a host of other conditions are "cured"? Such patients are admitted to hospital for observation and investigation followed by a "treatment" which enables them to maintain a prescribed regime. The function of psychotherapy is in many respects similar. Certain personality weaknesses are akin to many organic conditions in that they cannot be radically altered (except perhaps by a lengthy treatment of unwarrantable cost). The patient is brought to hospital in an acute state because he has been subjected to a strain beyond the limits of his emotional integration. He needs help, if only to recover his former adaptations, and in the course of treatment the environment with which he may be expected to cope successfully may be ascertained. The enormous number of pensions for war neuroses following the last war shows that mere discharge to civil life is not sufficient. Nor, in our opinion, is treatment in hospitals enough. Men have usually to be discharged to their homes when the severity of their symptoms is so reduced that they will not further tolerate the inevitable restrictions of hospital life. Sometimes symptoms are still disturbing, and it is desirable that provision for subsequent psychotherapeutic help, say in out-patient clinics, should be made to aid these men towards successful adjustment. Such help, of course, could only be an accessory in the task of placing these cases in a useful role in society—a task essentially socio-psychological.

The average period in hospital for sufficient improvement to lead to discharge was about seven weeks. By this time, in our series, 15 men were much improved, 65 improved, and 20 little changed (the last group included transfers to other hospitals).

The eventual disposal, of course, is a separate problem from the treatment of symptoms, for previous history has to be strongly emphasized when deciding the question of return to service. For example, depressed patients mostly made a complete symptomatic recovery; but where there was a history of recurrent attacks at intervals of less than a year, or where the degree of depression had been suicidal, discharge from service was recommended. Discharge from service was also advised for anxiety cases with bad histories, for gastric cases, and for most cases of effort syndrome. Strong dependence on the family was also taken as a bad prognostic sign, since Army conditions do not permit of men being categorized so as to remain near their homes. In the hysterical group visual and massive gait disturbances were thought to warrant discharge because of the total incapacity produced by any recurrence.

Of the groups based on previous history all of Group 1 (men with previous psychoneuroses) and a large fraction of Group 2 (men with character disturbances or latent psychoneurotic conditions) were discharged. In Group 3 (men with previous temperamental instability) just over one-half were returned to service, though, according to follow-up reports, not with much success; three of these men returned to hospital within a few weeks. With most of this group there seemed to be a feeling that it was time for another change, and their consciences were satisfied

with having "done their bit." The older men in Group 4 (no previous history) were discharged; but most of the younger half returned to duty, many to full service.

External factors had also to be considered in disposal; for instance, though some men might have been regarded as fit for a lower grade of service, subsequent breakdown was likely if recategorization meant doing work which did not employ their talents in some useful way, or which, in an ambitious conscientious man, would interfere with promotion.

Of those men returned to a lower grade of service it was learned from follow-up inquiries that 4 were afterwards discharged from other hospitals. Follow-up replies were not obtained for all cases, but from those received about half the men were stated to be serving satisfactorily. Thirteen men were transferred to other hospitals: 7 because of psychosis or suicidal impulses, 3 for anti-syphilitic treatment, and another 3 for other treatments. It is probable that 10 of these were eventually discharged (the 7 with psychosis or suicidal impulses, plus 3 of the others) and that the remainder returned to duty in a lower category.

The final results, then, might be stated thus: 72 men were discharged from service, 19 returned to a lower grade of service, and 9 returned to full duty.

Summary

Observations on 100 men suffering from psychoneurosis following combatant service showed that 80 of them had had previous traits indicating emotional instability. The illness of 36 men was merely an aggravation of previous psychoneurosis, and in 33 it was associated with a definite predisposition to breakdown. Temperamental instability, revealed by frequent changes of job, was present in 11. Of the 20 men with no previous history one-half were much older than the rest of the group, and the disturbances in the younger half were mild.

Some observations are made on the possible selection of these cases and on their treatment and psychopathology.

When the liability to further breakdown was taken fully into account the recommendations for future disposal led to 72 of the group being discharged, 9 returned to full duty, and 19 returned to a lower grade of service.

[Since the above paper was written a new scheme has been developed whereby it will be possible to have psychoneurotic soldiers placed in work suited to them and, if necessary, near their homes. This highly commendable innovation will be followed with much interest.]

I wish to express gratitude to the Department of Health for Scotland for permission to refer to these cases; to Dr. C. D. Bruce, physician-superintendent of the hospital, and to my colleagues, for much helpful criticism; and to my wife for most of the work involved in tabulation.

Raven, J. C. (1939). *Brit. J. med. Psychol.*, 18, 16.

J. V. Greenebaum, W. Felson, and M. Zeligs (*J. Pediat.*, 1941, 18, 799), who give the history of a fatal case in a female infant aged 1 year, recall that acute interstitial myocarditis is a rare form of heart disease which was first described by Fiedler in 1890. The clinical picture is one of progressive myocardial failure unassociated with the usual causes of myocardial damage. In 1929 Scott and Saphir were able to collect only 38 cases in the literature, the youngest of which was in a child aged 3 years. The diagnosis is very difficult, and according to Maslow and Lederer, writing in 1933, has never been made before death. The disease should be borne in mind in cases of prolonged tachycardia in infants and children in whom no other cause for it can be found.

FRAGARINE: AN INHIBITOR OF UTER ACTION

(Preliminary Communication*)

BY

Sir BECKWITH WHITEHOUSE, M.S., F.R.C.
F.R.C.O.G., F.A.C.S. (Hon.)

(From the Department of Midwifery and Diseases of Women, University of Birmingham)

In certain areas of Herefordshire and Worcestershire, probably elsewhere, it is a common practice for women to use an infusion of dried raspberry leaves to allay pains of labour. The same "tea" is also employed empirically, with apparently satisfying clinical results, in some cases of dysmenorrhoea. It seemed, therefore, that an investigation into the pharmacological aspects of raspberry leaves might be interesting, and in May, 1940, with end in view I approached Mr. E. C. Bennison, chair of the Advisory Committee of the School of Pharmacy, Birmingham. Mr. Withell, head of the School of Pharmacy, kindly undertook to prepare extracts and to isolate, if possible, any active principle that might be present. Work was started in August, 1940, and when enough material was obtained the extracts were submitted to F. J. H. Burn, University Department of Pharmacology, Oxford, for pharmacological trial. In March, 1941, I received from Prof. Burn the following account of observations.

"I began by making experiments in the spinal cat, in which relaxation of the uterus is readily observed. If an infusion of raspberry leaves is made in the same way as tea, and if the infusion is concentrated by evaporation under reduced pressure then an injection of an amount of infusion equivalent to about 2 grammes of dried leaves produces a momentary fall in blood pressure, followed by a conspicuous rise, and simultaneously a relaxation of the uterus of the non-pregnant cat. It will be remembered that the sympathetic innervation of the uterus is inhibitory.

"This effect resembled that which is produced when a dose of nicotine is injected, which simultaneously produces a rise in blood pressure and relaxation of the uterus. The action of nicotine is known to be due to stimulation of the suprarenal gland resulting in liberation of adrenaline, and also to stimulation of sympathetic ganglia resulting in a discharge of inhibitory impulses down the hypogastric nerves. It was found that the initial fall in blood pressure played no part in the action on the uterus, because in cats anaesthetized with chloralose no initial fall of blood pressure was observed.

"In further experiments, in which the suprarenal glands were first excluded from the circulation and in which the hypogastric nerves were cut, the injection of raspberry extract produced relaxation, and, indeed, the effect observed was a small but well-maintained contraction.

"Further experiments were then done on the isolated uterus removed from the body and suspended in a bath. It was found that the extract produced a contraction of the uterus of both cat and the guinea-pig, fairly prolonged in action and much more likely to represent any effect which may be observed in patients drinking raspberry tea. It is interesting to observe that the amount of extract producing an effect in the bath on an isolated organ is about 1/100 part of the dose which is taken by a patient drinking 10 oz. of a 5% infusion of dried raspberry leaves. The dose of pituitary extract which must be added to the bath to produce a similar effect is also about 1/100 part of the human dose.

"Attempts are being made to concentrate and purify the active principle responsible for the action on the isolated uterus. I do not know at present whether this principle is the same as that which produces inhibition of the uterus in the anaesthetized cat.

* Received for publication on August 1, 1941.

cat. If one substance is responsible for both effects its properties resemble those of the alkaloid hydrastinine, which was shown by Laidlaw in 1911 to have similar effects to those we find exerted by raspberry extract.

"It remains to add that raspberry extract has no action on the isolated cat heart."

On June 14, 1941, Burn and Withell (1941) brought before the Physiological Society of Great Britain, at a meeting held in Birmingham, a more detailed account of the work so far accomplished. On that date also the first clinical observation was made in my department at the University of Birmingham.

To obtain a record of the clinical effect of "fragarine"—the name we propose for the active principle in question—the intra-uterine-bag method described by Bourne and Burn (1927) and modified by Chassar Moir was employed. It is unnecessary to describe in detail the earlier experiments.

FIG. 1.—Showing the inhibitor effect of the administration of 40 grains of crude extract of dried raspberry leaves containing fragarine upon the spontaneous contractions of the human uterus on the fifth day of the puerperium. The arrow on the tracing marks administration of the extract. The divisions of the base line show intervals of one minute.

FIG. 2.—Uterine contractions after pituitrin are shown in the first tracing. The poor response of the uterus to pituitrin given after fragarine is shown in the second tracing. The arrow on the upper tracing marks administration of pituitrin 5 units. The first arrow on the lower tracing marks administration of raspberry-leaf tea 20 oz. 5%; and the second arrow, pituitrin 5 units. Divisions of the base lines show intervals of one minute.

but the following records provide in our opinion adequate clinical evidence of the inhibitory action of fragarine upon the human uterus.

Case Reports

Case 1.—A 1-para. Fifth day of puerperium. The uterus was anteverted and the fundus extended two inches above the symphysis pubis. The cervical canal admitted two fingers, and the intra-uterine bag was introduced without difficulty at 2.50 p.m. Spontaneous contractions of the uterus were recorded as shown in Fig. 1. The blood pressure registered 110/58 mm. At 3.15 p.m. 40 grains of raspberry extract (Ext. 49a) were administered by mouth. At 3.45 p.m. the blood pressure showed a reading of 106/58. The effect of fragarine upon the uterine contractions was to inhibit them. At first the contractions became less frequent, and finally they ceased altogether (see Fig. 1). No toxic effects of the extract were evident.

The effect of fragarine upon uterine contractions initiated by the administration of pituitary extract is shown in Case 2.

Case 2.—A 7-para. Eighth day of puerperium. Uterus involuted to size of twelve weeks' gestation and retroverted. The cervix admitted one finger, and the intra-uterine bag was inserted at 5.30 p.m. The blood pressure registered 120/70. Five units of pituitrin were administered at 5.55 p.m. At 5.45 p.m. the blood pressure was 126/72, and 20 grains of extract (49a) were administered. At 6 p.m. the blood pressure registered 112/70, and a second dose of pituitrin (5 units) was given. The effect of fragarine upon the uterine contractions was to

diminish their frequency and strength and to eliminate secondary contractions. This is indicated in the lower tracing in Fig. 2.

Case 3.—An 8-para. Fifth day of puerperium. Uterus anteverted and fundus extended two inches above the symphysis pubis. The cervical canal admitted two fingers. At 3.15 p.m. the intra-uterine bag was adjusted. The blood pressure was 100/62. At 3.30 p.m. 10 units of pituitrin were given. At 5.50 p.m. the blood pressure registered 112/58, and 20 grains of extract (49a) were administered by mouth. At 4.10 p.m. the systolic blood pressure showed a slight fall to 106. A tracing of uterine contractions similar to that shown in Fig. 2 was obtained.

Discussion

These experiments, *inter alia*, seem to confirm in the case of the human puerperal uterus the observations made by Burn and Withell on the uterus of the non-pregnant cat. The main effect is one of relaxation of the uterine

muscle. Contractions are diminished in force and frequency, secondary contractions are eliminated, and such contractions as occur are evenly spaced. The effect of fragarine upon the blood pressure is less pronounced in the human species in such concentrations and doses as have been applied. It is true that a very slight fall in the systolic pressure is noticeable, but there is no subsequent "conspicuous rise" as noted by Burn in the spinal cat.

It is obvious that further work remains to be done both from the pharmacological and from the clinical aspect, but apparently in fragarine we have available an active principle that may have a useful clinical application in the treatment of irregular routine action during labour and menstruation. In the absence, as yet, of any more elegant preparation, crude raspberry-leaf tea is being used in one of the Worcestershire maternity hospitals, and the nursing staff report favourably upon its effect in "making things easier."

In concluding this preliminary report of work still in progress my thanks are due not only to Mr. Bannison, Mr. Withell, and Prof. Burn for their active co-operation, but also to Prof. Gilding of the Department of Physiology, University of Birmingham, Prof. Chassar Moir, Oxford, and my registrar, Miss Terry, for valuable help in completing the clinical investigations.

SOME CONTRIBUTIONS TO WAR SURGERY FROM THE U.S.S.R.*

BY

RUSCOE CLARKE, M.B., F.R.C.S.

First Assistant in Surgery at the British Postgraduate Medical School

War surgery is the continuation of the surgery of peace under somewhat different conditions. War demands adaptations, modifications, and development of technique and organization. It stresses the importance of some fields of surgery at the expense of others. It should be possible, however, to get some idea of the capacity of the surgical services of a State to react to war conditions from a study of their functioning in times of peace. I shall therefore introduce a description of the work of certain Soviet institutions, the consideration of which should lead us to expect from the Soviet Union a high standard of war surgery. At the same time it is important to consider developments in Soviet surgery in their relation to progress elsewhere, to the general evolution of surgical knowledge and technique. Our past ignorance must not allow us to regard Soviet surgery as something peculiar. Up to a point methods of research are similar and work advances along orthodox channels. We have to see the similarities as well as the differences.

As a start, then, I shall refer briefly to the past. It is impossible to assess the importance of what is happening to-day unless we can achieve some sense of historical perspective. Nowhere is this fact so well recognized as in the Soviet Union. The new Soviet State has been continually alive to the need to preserve the best from the past. Great attention is paid to the work of early pioneers and outstanding individuals in the history of science.

Historical

In this connexion one man stands out in Russian history—Nikolai Ivanovich Pirogoff (1810-81). He is regarded as the founder of Russian surgery. His chief individual contributions were concerned with wound infections in hospitals, ether anaesthesia, and the details of the organization of surgical aid for the wounded in war. It is claimed that he was the first to introduce the plaster wound dressing into military field practice, in the Crimean War in 1854 (Shmarevich). He recommended plaster as the best dressing for amputation stumps in 1855 and advocated the windowless plaster cast for open gunshot wounds of the legs. Pirogoff was a great man, and in the French literature has been compared to Ambroise Paré himself. No insignificant monument to him remains in the Military Academy of Medicine in Leningrad, which he developed into the finest school in the country. The school has continued, and only recently has produced important studies on the prevention and treatment of painful amputation stumps and scars by the early injection of novocain (Astvatsatourov, 1938).

Worthy upholder of the best traditions of the past and a link between the past and the future is Nikolai Nilovich Burdenko (see reference: VOKS), head of the Neurosurgical Institute, member of the Academy of Sciences, awarded the Order of Lenin for outstanding services in the field of surgery, active as President of the Medical Council of the People's Commissariat for Health, Chairman of the All-Union Association of Surgeons, and Deputy to the Supreme Soviet of the Union of Soviet Socialist Republics. Here is a man who obtained his initial experience and training before the revolution but has since been able to develop his work in all spheres of surgery. Recently his

attention has been concentrated upon the establishment of a Russian school of neurosurgery. But his life's work has ranged over many fields in anatomy, physiology, experimental surgery, pathology, and general surgery. He is responsible for original work relating to the surgery of the lungs, gastric ulcer and carcinoma, shock, etc., as well as in the more limited field of neurosurgery. In addition to all this he is one of the outstanding experts on military hygiene and surgery, and his book on military field surgery is regarded as a classic.

Soviet Institutions

Typical of the best in the organization of Soviet medicine and directly relevant to a study of Soviet preparedness for war surgery is the Central Emergency Hospital in Moscow (the Sklifasofsky Institute) (1937) (Sigerist, 1937; Band 1937-8). The Moscow district is served by five emergency motor ambulance stations, one of which is placed centrally at the institute, where there is a special telephone exchange. Urgent calls are received here, and the central station is responsible for sending out ambulances to accidents and cases of sudden illness.

There are two types of ambulance service. The first is for emergencies such as street accidents, factory disaster and sudden collapse, and for genuine surgical emergencies when the call comes from a doctor prepared to make definite diagnosis. The ambulance is sent immediately, and the medical and surgical staff are informed so that full preparation can be made. If a delay of more than two minutes occurs before the ambulance leaves the hospital an inquiry is held. The second type of service is used when a call is put through by relatives or strangers—if the case sounds convincing but is clearly not so urgent. Such cases have to wait their turn for a car, which will probably be sent within two hours. When the case is not considered to be the doctor on telephone duty to come under this category the station recommends that a local doctor be called in, or gives the telephone numbers of local doctors and of the nearest hospital. It is important to note that no doctor employed on the staff of the institute who has been qualified less than ten years. Long years of practice have made possible to elaborate a series of leading questions and other means of eliminating serious error from this system of telephone sorting. In 1936 this ambulance service made 59,156 trips. The number of beds available is about 70 of which more than half are surgical. The medical staff numbers 100, with another 70 available for shifts on first aid duty. The concentration of cases allows the surgical staff to amass a wide experience. Adequate records enable this material to be available for study and assessment of the results of different techniques (Grey Turner, 1938).

The most remarkable surgical work of the institute, apart from the original work on stored cadaver blood, is that of Prof. Judin. During a nine-year period 1,400 perforating peptic ulcer cases came under the care of his unit. These, 75% were treated by partial gastrectomy. In 1933 the mortality figure for gastric resection in 331 perforating ulcers was 7.8%. Prof. Judin is also an advocate of resection in bleeding ulcers, claiming a total mortality 4.4% for all gastric resections performed in the institute. The main factor responsible for these results is the organization which makes early operation possible in a high proportion of such cases. Mr. David Band (1937-8), in an account of his visit to the institute, expresses his surprise and interest that under a State medical service "it was possible for emergency surgical specialist to extend his sphere of work to include not only the whole field of gastric surgery in addition the many-staged plastic operations necessary for the rehabilitation of cases of oesophageal stricture subjected by him to emergency gastrostomy." We can only hope

* A paper delivered at a meeting held on July 25, 1941, at the Medical Society of London under the auspices of the Society for Cultural Relations with the Soviet Union.

that at this present time the Moscow Casualty Services have been developed along similarly efficient and elastic lines.

A second institute, of a rather different type, illustrates the planned clinical research into the treatment of injuries. The Leningrad Traumatological Institute (Dott, 1937-8), with only 80 beds, is the centre for this research throughout the Union. It has a statistical department which assembles and studies figures for injuries incurred in various industries—in agriculture, transport, etc. The results are passed on to the Commissariat for Health, which is able to proceed with energetic steps for the removal of remediable causes. Key clinical problems—e.g., some particular type of fracture—are selected for special study, and cases of this type are concentrated at this institute. When completed the results are published in pamphlet form and sent out to all the hospitals in the Union. A system of orthopaedic clinics linked with the main hospital extends its sphere of influence and helps to provide clinical material. Postgraduate teaching is an important feature of the institute.

Here, then, we have two examples of specially planned institutions, working as an integral part of the general medical organization. I think we can assume that the adaptation of such hospitals and teams of experts to war surgery should not be difficult.

I propose now to deal with examples of recent Soviet contributions to war surgery which illustrate among other things the planning of research and the provision of opportunities for full clinical trial of the results of such research.

Local Anaesthesia

The struggle to perfect the technique of local anaesthesia has stimulated the development of surgery since the days of Halsted's original work. The use of local anaesthesia for major surgery demands a high degree of surgical skill, with particular need for gentleness and delicacy, such as characterizes the modern school of neurosurgery founded by Harvey Cushing, himself a product of the Halsted school. In recent years the range of possible use of local anaesthesia has been extended. Finsterer developed its use in gastric surgery, and Ogilvie has popularized his methods in this country. Böhler demonstrated its value in closed and open fractures. Many surgeons have increasingly extended its application, particularly as proposed by Crile in association with some form of general anaesthesia sufficient to produce unconsciousness.

The Soviet contribution in this field is threefold: (1) a new technique; (2) the new application of a new drug; and (3) the demonstration of the practicability of using local anaesthesia in all types of cases, even under war conditions.

The new technique was originated by Vishnevsky (1938). Injecting large quantities of a weak solution (equal parts of 0.25% novocain and 1/4,000 percaïne), he takes advantage of the normal anatomical fascial pockets surrounding muscles, viscera, etc., to get wide diffusion of the drug and rapid contact anaesthetization. Each aponeurotic layer is left intact until the underlying fascial compartment has been distended and anaesthetized. The fascial and aponeurotic anatomy of each region needs to be understood so that wide anaesthesia may result from a single continuous spreading infiltration from a chosen point. This technique of spreading infiltration can, it is claimed, be used everywhere except for the head and the extremities of the limbs. Vishnevsky describes in detail its application to the thyroid, to breast cancer and ventral hernia, abdominal cavity, biliary tract, renal fossa, and limbs. In the case of the fingers and toes a variation is used. Isotonic solutions are employed, and the soft tissues at the base of the digits are distended at first so that the risk of gangrene from circulatory interference is avoided. An important effect claimed is the minimization of post-operative shock. Already in

1938 Vishnevsky proposed that this technique should be tried out under war conditions. He quotes Crile's figures for major amputations during the 1914-18 war as illustrating the great reduction in mortality following the introduction of local anaesthesia. These conclusions are fully substantiated by the reports of Henry (1940) and Abdelsamie (1936) of their experience in the treatment of major limb crushes at Cairo. Vishnevsky goes further. He claims that the use of local anaesthesia by his technique is perfectly safe in the presence of local sepsis.

So much for the method. Stimulated by this, Synovich (1940) has carried out a series of clinical experiments using a Soviet preparation of percaïne (sovkaïn) in increasingly dilute solution for local infiltration anaesthesia. He claims that it is fully effective at a strength of 1/10,000. It is suggested that at this dilution it is safe to use up to 25,000 c.cm. Actually no more than 1,000 c.cm. was used for one operation. Complete skin anaesthesia is attained within one to two minutes and is maintained for four to six hours. Deep infiltration produces immediate anaesthesia. No toxic reactions were reported.

The next stage is represented by the reports of Novikov (1940) from Moscow. He discusses 3,180 emergency operations, 98% of which were performed under local anaesthesia. Ages varied from 3 to 83; 37.5% were traumatic cases. Sixty-five cases of penetrating wounds of the abdominal cavity were treated, with a mortality of 36.8%. This compares favourably with a mortality of 55% for similar cases during the Lake Hassan incident. One hundred and fifty-four major amputations were performed under local anaesthesia, with a mortality of 14.7%, as compared with Akbutin's figure of 18.7% at Lake Hassan and 22.8% given by Belkin as the general mortality for all amputations of the lower limb in the Ukraine. The technique used was that of Vishnevsky. The trial of this technique under war conditions was carried out by Pschenichnikov (1940) and a team of surgeons during the Finnish campaign. A large series of unselected casualties was operated upon under local anaesthesia side by side with other surgeons working with general anaesthesia in two-table theatres. They were able not only to demonstrate the possibility of using local anaesthesia under these conditions but to refute the objection that this would mean an unnecessary lengthening of the operating time. They showed that such delay can be avoided even in cases with multiple injuries. Their cases were fit for evacuation much earlier than the others. The decrease in post-operative shock is stressed and the preliminary anaesthetization is regarded as part of the pre-operative treatment of shock. Thus many of the theoretical objections to the use of local anaesthesia in war surgery have been removed.

Electrical Trauma

The most comprehensive recent survey of this subject is contained in a lecture given by Kaplan (1940) of the Moscow Town Health Department for the Study of Electro-trauma. Modern military technical equipment makes wide use of electric power. Soldiers are exposed to danger of injury from electric current from their own power stations as well as from electrified wire entanglements and other new electrical means of attack and defence. Pathologically and clinically it is essential to realize that the external evidence of trauma is only a small part of the picture. All the tissues of the body, particularly the blood vessels and the nervous system, are exposed to a severe disorganizing influence. An important practical effect of the deep-seated nature of the disturbance is the long duration of treatment and the need for evacuation of any but the most trivial cases. Within two or three weeks the area of apparent damage

may have extended to twice or three times the original size. A surrounding zone which at first seemed likely to survive becomes necrotic. The base of a blister breaks down and becomes a deep ulcer. Adjacent blood vessels are involved in this necrosis, and severe secondary haemorrhages occur between the third and fourth weeks. Bone involvement results in slowly separating sequestration. Systemic reactions are varied and complex. Death may be instantaneous or may follow a short period of respiratory difficulty, haemorrhage, and cerebral disturbance. A condition of so-called "pseudo-death" is described, with cessation of heart-beat, respiration, and all reflex and nervous activity, without cellular death. Rapid active resuscitation may result in recovery. The onset of the condition may follow a latent period of a few hours.

The scope of first-aid treatment obviously depends upon local conditions. Where the shock is received during military operations it is clearly impossible to give prolonged treatment on the spot. The urgent need is for speedy evacuation. For this purpose a tank with a trap-door in the bottom has been devised. This moves over the casualty so that the man lies between the caterpillars, and can be lifted through on to a bed, where treatment is begun. Immediate treatment usually involves artificial respiration. Stimulant drugs may be given intravenously. Resistance to chilling is low. Cyanosis may require venesection. Severe circulatory collapse may respond to transfusion. Should there be no sign of life the patient must not be given up as dead until visible signs of death appear or stiffness sets in. Movement should be avoided if conceivably possible. A possible addition to routine restorative measures is the electrical stimulation of the phrenic nerve by application of an electrode over the lower part of the sterno-mastoid.

Treatment of external injuries is similar to that for thermal burns. Even the smallest marks, however, require full cleansing and application of coagulants, since these may become macerated and septic as a result of the excessive sweating. Primary amputation is generally inadvisable. It is difficult to define the limits of necrosis. Blood vessels are rigid, bleed violently, and tear across when forceps or ligatures are applied. Stumps become septic and the infection spreads rapidly.

Chest Wounds

[An account of recent British work in this field is omitted for lack of space. The reader is referred to the discussions (1940a, 1940b) held at the Royal Society of Medicine and to the *Bulletin of War Medicine*, 1941, No. 5.]

The available Soviet material in general confirms recent British experience but reveals a number of interesting new aspects. Papers by Linberg (1940) and Matseyev (1940) are based on a series of 972 casualties from the Finnish front treated at a special military hospital for chest wounds between November, 1939, and May, 1940. These included 263 with open pneumothorax and 96 with closed haemothorax. In 97 cases these chest wounds were complicated by severe injuries elsewhere. The total fatalities were 29 (3%). Of these, 12 resulted from severe combined thoracic and other injuries, including 5 cases of gas gangrene. The remaining 17 were from the effects of the chest wounds alone. Comparison with other figures is difficult on account of the very different stages at which these patients reach hospital. Ranson, an American surgeon working at Shanghai, gives mortality figures for chest wounds in hospitals for some of the various wars of the past century:

English Army in the Crimean War	79.2%
American Army in the Civil War	62.6%
German Army in the Franco-Prussian War ..	24.5%
English Army in the Boer War	14.0%
English Army in the 1914-18 War	27.5%
Chinese hospital at Shanghai, 1937	14.8%

The low figure for the Boer War is attributed to the climate and to the high proportion of bullet wounds. The last figure is explained by the fact that the cases with severe wounds did not reach hospital at all. Burdenko carried out a differential analysis of the fatalities from chest wounds on all fronts during the 1914-18 war. He gives a general mortality of 60 to 80%, reduced at primary hospitals to 30 to 40% and at base hospitals to 15 to 35%. In the light of such figures the present series merits careful study. Of these cases 2.5% reached hospital on the first day, 53% between the second and fourth days, 24% between the fifth and seventh days, and 20.5% between the eighth and twentieth days. Wounds of the thoracic wall and uncomplicated bullet wounds of the thoracic cavity gave little trouble and require no special comment.

Bullet and shell wounds with open pneumothorax constituted the most serious group. The 17 deaths from chest wounds alone came under this heading, comprising 6% of 263 cases. Of these, 246 (94%) had been sutured and only 17 extensive wounds left open. In the majority the muscle only had been sutured. Where the skin had been closed, spreading infection and surgical emphysema had developed. No previous operation had been carried out on the lung or pleural cavity. The chief problem in these cases of wide-open pneumothorax is that of keeping the wound closed and avoiding mediastinal flutter. Aspiration of all collections of blood prevents wound disruption from pressure. The lung is drawn out into contact with the chest wall and adhesions can occur. Where this happens residual accumulations can be dealt with as indicated. Where adhesions fail to form the wound is sealed by overlapping watertight strapping. In this group a number of operations were necessary for the removal of foreign bodies. Attempted suture of the lung when infection was established was found to be unsatisfactory.

Stimulated by this experience, Verhovich and Ignatovskaya (1940) carried out an extensive series of animal experiments. Their conclusions may be summarized as follows: (1) Either the thoracoscope or the cystoscope may be used with advantage in the exploration of open wounds of the thoracic cavity. (2) Increasing haemorrhage should be dealt with by lung suture and pneumopexy. (3) Where this is impracticable valvular suction drainage should be substituted. (4) Suture of the wound around a drainage tube with a 5-mm. orifice did not prevent the onset of severe symptoms. (5) Substitution of a tube with a 2-mm. orifice brought about improvement and allowed further exploration within twenty-four hours. (6) Mattress sutures produce necrosis of the lung tissue and should be avoided. On the basis of this work and of the general experience of the hospital, instructions were issued to those working in the advanced posts to attempt more radical primary intervention wherever possible in open pneumothorax.

The other important group, discussed particularly by Matseyev (1940), consists of the cases of closed haemothorax. Until recently these had been treated conservatively, but existing evidence suggests that early aspiration is the treatment of choice. Complete evacuation of the blood by repeated aspirations under radiological control is begun on the third or fourth day. This is combined with irrigation with mild antiseptic solutions—chloramine 1/500 or rivanol, 50 to 100 c.cm. This technique is substituted for air replacement on the basis of clinical and experimental evidence. Of the 96 cases only 2 became infected, and there were no deaths. Much of the general success obtained in this series is attributed to the fact that 65% of the cases were transported from the front by air. The condition of these, including many of the most severely wounded, was far and away better than that of those brought back by road. Other factors besides that of efficiency of organiza-

tion suggested as explanations of the excellent results were: (1) the magnificent state of health of the soldiers; (2) the predominance of bullet wounds; (3) correct treatment.

Another contribution to the surgery of chest wounds consists of a report to a conference of evacuation hospitals by Achutin (1940). It covers all chest wounds in the war zone during the Finnish campaign. No adequate justice can be done to this contribution in the space available, and only a few of the more important conclusions will be mentioned. With reference to the recommendations of Prof. Linberg, referred to above, Achutin admits that up to the present the problem of major surgical intervention in the war zone for open wounds of the chest has not been solved. Satisfactory results have been obtained only when cases have been seen within one to two hours and when the lung could be seized through the wound, sutured, and fixed to the parietes. Personal observations have led him tentatively to advocate the trial of vago-sympathetic novocain block as additional treatment for shock. The report reiterates the importance of air transport and of the different attitude which can be adopted towards these cases where such transport is available. This was especially important during the campaign in the far north, where the intense cold produced a high incidence of pneumonia, which developed about the fourth or fifth day. Evacuation after recovery from the initial shock and before the time of onset of these chest complications would appear to have been almost ideal.

Congratulating Prof. Linberg and the special unit on their magnificent work, Achutin points out that the total mortality is still high. As many as 40% of chest-wound cases do not leave the battlefield, while 20% of these patients die before the base hospital is reached. The solution of this problem requires the full application of all the available organizational, experimental, and clinical experience.

Conclusion

The march of history has done much to sweep away the veil of distrust which has separated the people of Britain from the people of the Soviet Union. I hope that this meeting will serve three purposes: first, to begin the removal of that prejudice and ignorance which has interfered with our understanding of the development of Soviet medicine and surgery; secondly, to help to get an understanding of some of the things which the Soviet people are fighting to defend; thirdly, to obtain some ideas for the improvement and reorganization of our work here.

Whatever success we may have to-day can only be a beginning. British medicine has much to contribute to the exigencies of this common struggle. We have a great deal to give, but we have plenty to learn.

THE REDUCTION OF HOSPITAL INFECTION OF WOUNDS

A CONTROLLED EXPERIMENT

BY

W. McKISOCK, M.S., F.R.C.S.

JOYCE WRIGHT, D.M.

AND

A. A. MILES, F.R.C.P.

(From an E.M.S. Neurosurgical Unit)

The demonstration by Miles *et al.* (1940) of a high incidence of hospital infection of wounds, and the recommendations formulated by them to reduce this incidence, were based in part upon investigations made on patients treated in this unit. It was thereupon decided to attempt the development of a dressing technique which would eliminate hospital infection as completely as possible.

Conditions of Experiment

The value of modifications in dressing technique was judged by the reduction of hospital infection observed in a four-months period from February 1 to May 31, 1941, as compared with a previous four-months period from September 1 to December 31, 1940. The intervening period of January, 1941, was excluded, since during this month the new dressing technique was being evolved and perfected.

In the two periods the underlying conditions were essentially the same. The clinical material handled was similar, consisting (1) of cases of head injury, mainly air-raid casualties whose wounds were infected at the time of admission; and (2) of neurosurgically clean cases, mainly intracranial tumours. The employment of chemotherapy was on the same basis during the two periods, and, finally, the personnel concerned with the dressing of wounds remained relatively unchanged throughout the entire eight months of the experiment.

The Improved Dressing Technique

The dressing technique here described was designed on the assumption that the main cause of hospital infection demonstrated in the first four-months period was the carriage of infected discharge from one patient's wounds to another's by members of the medical or nursing staff, settlement from the air and droplet infection being less important. Our aim was to combat the spread of infection in as simple a manner as possible—contact infection by the dressing technique itself, dust-borne infection by Rules 1, 2, and 6 in the instructions below, and droplet infection by Rules 3, 4, 5, and 9.

It was found impossible to reduce the dressing team to fewer than four persons unless dirty-dressing bins with foot-action lids could be procured. With this addition to the equipment the team could be reduced to a minimum of three. The first member of the team is the dresser, who begins his work when the bandage and outer dressings have been removed from the wound, finishing by applying the new bandage assisted by the "dirty nurse," after which he washes his hands and forearms and dries them on an ordinary towel. The "clean nurse" looks after the trolley and its contents only, touching nothing throughout the entire dressing round, and washing her hands and forearms only at the beginning and end of the series of dressings. The "dirty nurse"—an indispensable member of the team—removes the outer dressings and bandage and then stands by until the end of the dressing, when she assists in the application of the final bandage, afterwards washing her

hands and forearms. The bin porter carries two bins (one for washable soiled dressings and the other for dressings which must be destroyed) from one bed to the next, removing the lids and replacing them as required. He washes his hands and forearms at the beginning and end only of the round of dressings.

The dresser and "dirty nurse" therefore wash between each case, while the "clean nurse" and bin porter wash at the beginning and end of the dressing round, remaining "clean" and "dirty" respectively throughout. None of the team "scrubs up" in the surgical sense. The nurses wear ordinary uniform; the dresser works in shirt-sleeves.

Instructions Issued to Ward Personnel

GENERAL RULES FOR DRESSING

1. All bed-making, sweeping, and other activities likely to raise dust to finish half an hour before the start of dressings.
2. All windows allowing draughts, and the entrance doors to the wards, to be closed at the start of the dressing and kept closed.
3. All persons attending the dressing or having occasion to be near the dressing trolley or sterilizer must wear masks, consisting of two layers of gauze interleaved with impervious material (e.g., paper, cellulose acetate).
4. All persons such as ward maids, porters, and patients' visitors to leave the ward.
5. Any person entering the ward unavoidably must take a mask from the supply ready at the door of the ward and adjust it correctly.
6. No more than one dressing to be uncovered at the same time.
7. For patients with more than one dressing the full procedure must be observed for each separate dressing.
8. The door of the service room containing the washing sinks must be fixed open so that there is never the need to touch the door-handles.
9. No person having an infected lesion of the hand or with a sneezing cold to participate in the dressings.

TECHNIQUE OF DRESSING

1. Four persons only to take part in any one dressing: (a) the dresser; (b) the "clean nurse"; (c) the "dirty nurse"; (d) the bin porter.
2. The "dirty nurse" removes the safety pins and places them in a dish for sterilizing.
3. The "dirty nurse" removes all the outer dressings unaided and places them in covered enamelled bins, one for soiled dressings and the other for apparently clean dressings. The lids of these bins will be removed and replaced by the bin porter.
4. The "dirty nurse" then raises the patient's head.
5. The dresser places a towel beneath the head.
6. The "clean nurse" passes all dressings to the dresser with two pairs of sterile forceps.
7. The dresser carries out the dressing, using another two pairs of sterile forceps.
8. No contact between the two sets of forceps is permitted.
9. The dresser then places the dirty forceps in the sterile kidney bowl offered by the "clean nurse."
10. The dresser applies the final bandage, assisted by the "dirty nurse."
11. The "dirty nurse" takes the dresser's forceps in the kidney bowl, washes them with a wire brush in lysol, and places both instruments and bowl in the sterilizer, the lid of which is held open by the "clean nurse."
12. The "dirty nurse" washes her hands and forearms.
13. The dresser washes his hands and forearms.
14. The instruments are removed from the sterilizer by the "clean nurse," who places them on the trolley for the next case.
15. The bins for the dirty dressings are carried from one bed to the next by the bin porter.
16. At the end of the round of dressings the bin porter washes his hands for the only time.

Note.—None of the team "scrubs up" in the surgical sense of the term; each member starts work with hands and forearms washed with soap and hot water and dried on a clean towel. The "dirty nurse" washes her hands and forearms after each dressing, as does the dresser. The "clean nurse" after the initial wash does not wash throughout the periods of the dressings.

NURSING RULES

1. Washing of Patients.—A personal bath blanket to be kept in each patient's locker. Baths to be disinfected with lysol, and washing-bowls to be steeped for ten minutes in 5% lysol each time they have been used.
2. Bed-making.—All bed-clothes, pillows, and mackintosh sheets to be placed on chair at foot of bed and never transferred from one bed to another.

3. Soiled Linen, etc.—Bed-linen to be laundered in the usual manner. Face-flannels to be boiled. Blankets and pillows to be "stoved." Mackintosh sheets, combs, and brushes to be disinfected with 5% carbolic, and bedsteads and lockers with 5% lysol. Used linen for laundering to be placed immediately in a bin kept for that purpose. Linen soiled by discharges, pus, etc., to be soaked in 5% lysol before laundering.

4. Infected Patients.—Nurses must so far as is possible prevent infected patients from passing articles (books, newspapers, etc.) to other patients.

Sources of Infection

The hospital infection rate was determined with regard to *Streptococcus pyogenes*. The similarity of the sources of infection in the two periods is evident from the following surveys of the likely reservoirs of *Strep. pyogenes* in the unit—namely, air, throats, and wounds. All cultures from swabs and air exposures were made in blood-agar plates, and each colonial form of any haemolytic streptococci that appeared was sampled for grouping by Lancefield's method. Only those falling into Lancefield's Group A were regarded as potentially pathogenic *Strep. pyogenes*.

Air-borne Infection.—No systematic observations of air-borne streptococci were made in the first period; a few plates exposed during dressing-time yielded an occasional *Strep. pyogenes* colony. In the second period the deposition of *Strep. pyogenes* particles was measured, twenty-two times, from 7 a.m. to 10 a.m., by exposing plates in both male and female wards. The bacterial counts were similar to those previously described (Brown and Allison, 1937; Miles *et al.*, 1940), reaching peaks during bed-making and sweeping. During these busy periods in the female ward an average of 7, and in the male ward an average of 9.6, *Strep. pyogenes* particles were deposited per hour on an area of one square foot. A few series of counts made throughout the day showed that during the quiet period (Rule 1) there was a reduction of 90% from an average number of about 8,000 bacterial particles deposited per hour on a square foot in the peak period, and it may be assumed that at dressing-time air-borne *Strep. pyogenes*, though correspondingly reduced, was nevertheless a source of potential infection.

Throats.—Throat swabs of patients, doctors, nurses, ward maids, and all other frequenters of the department were taken at intervals of not more than a fortnight throughout the two periods of investigation. The number of persons carrying *Strep. pyogenes* in the throat in each of the three groups—staff, female patients, and male patients—at any one period varied between 0 and 3, though periods when no throat carriers were found were infrequent. At no time was the community as a whole free from throat carriers. In the two wards the incidence was similar; reckoned on the basis of fortnightly sampling, 12% of all persons in the unit during the first period were carriers at one time or another, and 10.1% in the second period.

Wounds.—Wound swabs were taken from all air-raid casualties at the first dressing after admission, and subsequently as opportunity arose, usually twice weekly. First swabs were cultivated both aerobically and anaerobically; subsequent swabs, if the first swab had yielded no obligate anaerobe, were tested aerobically only. From "clean" cases swabs were taken if sepsis developed.

The reservoir of *Strep. pyogenes* contributed by infected wounds existed throughout almost the entire eight-months period. For two spells of twenty days and fifteen days in the second period there was in the male ward no patient with a wound discharging these organisms; during these spells, nevertheless, *Strep. pyogenes* was present in the air and in the throats of several of the community as a potential source of hospital infection. In the female ward there was a constant reservoir in one or more wounds. The

wounds discharging *Strep. pyogenes* comprised those which became infected in the ward (see table) and those which were already infected with this organism on admission. Of the latter there were in all in the first period 3 (2 in the

Table showing Incidence of Hospital Infection of Head Wounds with *Strep. pyogenes* in Two Four-month Periods, before and after Introduction of Improved Dressing Technique

	1st Period	2nd Period
Air-raid casualty wounds:		
Number uninfected on admission...	32	46
Number of hospital infections	10	1
Percentage incidence of hospital infection	31.3	2.2
"Clean" operation wounds:		
Number operated upon...	46	49
Number of hospital infections	3	0
Percentage incidence of hospital infection	6.5	0.0

male ward and 1 in the female ward), and in the second period 11 (5 in the male ward, 6 in the female ward); therefore, including the patients infected on admission, there were altogether 15 streptococcal wounds in the first period and 15 in the second period.

Results and Discussion

The table records the incidence of hospital infection by *Strep. pyogenes* in the two periods. Hospital infection by haemolytic streptococci other than Lancefield A occurred during the first period, but has not been included in the analysis. It appears that a total infection rate of 15.4% has been reduced to 1.1% by the enforcement of the improved dressing technique and ward organization described above. A number of air-raid casualties admitted in the second period had in addition to their head injuries wounds of the trunk and limbs. Thirteen of these wounds were dressed by the improved technique, and in this group there was no streptococcal hospital infection. Six limb wounds, however, because of their minor character, were dressed without these improved precautions—a relaxation of procedure which proved to be indefensible, since three of them became infected with *Strep. pyogenes*. The result indicates clearly that a large risk of hospital infection was present in the unit during the second period.

The improved technique was devised for neurosurgical work mainly on head wounds. In surgical wards where wounds are larger in area or are exposed for longer periods, and where dressing involves more disturbance of bed-clothes (Thomas and van den Ende, 1941), air-borne bacteria may constitute a greater risk; and in wards where, for example, bathing and irrigation form part of the wound treatment here may be additional channels of infection important enough to warrant revision of the existing therapeutic methods. Nevertheless, it is possible that a greater relative reduction in incidence of hospital infection than that which we have recorded might be achieved in other surgical wards by the adoption of the improved dressing technique only. The technique originally used in the unit was considered to be bacteriologically safer than methods normally employed in general surgical wards, an opinion supported by the fact that the incidence of hospital infection in the preliminary observation period was lower than that obtained under war conditions elsewhere in the same hospital and in other hospitals.

It proved possible to maintain the improved dressing technique under the difficult conditions following the admission of a large number of air-raid casualties in a short period of time. At all times, and especially in times of stress, the intelligent co-operation of the nursing staff is essential if satisfactory results are to be obtained. We cannot praise too highly the work of Miss Mackinder, the sister in charge of the unit, and her nursing staff, without

whose help the improved technique could not have been put into effective use.

We have presented no data upon the ill effects of hospital infection, since they will form the subject of another paper; it may be said here, however, that the hospital infection produced serious complications in a small number of patients and a marked and significant lengthening of the average time of stay in hospital in the group of patients so infected.

Summary

During a preliminary observation period of four months the incidence of hospital infection with *Strep. pyogenes* among head wounds in a neurosurgical unit was 10, or 31.3% of 32 air-raid casualties, and 2, or 4.4% of 46 "clean" operation cases.

An improved dressing technique and a partially revised general ward procedure were designed to lower this rate of hospital infection.

During a test period of four months following the introduction of this technique as the routine method of dressing head wounds, the incidence of hospital infection with *Strep. pyogenes* was 1, or 2.2% of 46 air-raid casualties, and 0 of 49 "clean" operation cases.

Among the patients with head injuries treated in the test period were 19 with limb or trunk wounds. Thirteen were dressed by the improved technique, and there was no instance of hospital infection with *Strep. pyogenes* in this group. The remaining 6 were dressed without the improved precautions, and 3 of these, or 50%, became infected with this organism.

The conditions in the wards were essentially similar in the two four-months periods of investigation, and we attribute the striking reduction of hospital wound infection from 15.4% to 1.1% to the introduction of the improved dressing and nursing technique.

We are indebted to Dr. Herta Schwabacher, Dr. Joan Stokes, and Mr. E. P. Murrell for assistance with the bacteriological investigation; to Dr. Brian Browncombe for collaboration in the clinical work; and to the Medical Research Council for a personal grant to one of us (J. W.).

Medical Memoranda

Tenosynovitis of the Tendo Achillis

This condition has become extremely prevalent in infantry units. Forty cases have been investigated and the following observations made.

CLINICAL SIGNS AND SYMPTOMS

The patient complains of pain in the heel along the Achilles tendon. This is relieved by wearing light shoes, but reappears on wearing boots, particularly after marching. On examination slight swelling of the lower inch of the tendon sheath is apparent. There is usually one point extremely tender to pressure about an inch from the insertion of the tendon into the os calcis. On movement of the foot, flexion, and dorsiflexion, tendon crepitus is easily palpable in most cases. The crepitus is often felt along the whole course of the tendon from its origin in the muscle belly of soleus and gastrocnemius to its insertion. Clinically the condition is identical with simple tenosynovitis as seen in the extensor sheaths of the forearm.

This condition occurring in the Achilles tendon has been described as a bursitis. Tendo Achillis bursitis is a completely different clinical entity which generally follows some violent exertion—e.g., a cross-country run: the painful spot is usually nearer the point of insertion of the tendon, and there is complete absence of tendon crepitus.

AETIOLOGY AND TREATMENT

Tenosynovitis of the Achilles tendon is undoubtedly due to repeated minor traumata which, in my opinion, are caused by an abnormal focus of pressure in the boot. The forty cases were investigated with special attention to the following points:

1. Height of the man, and whether the pace is abnormally short. The height varied from 6 ft. 1 in. to 5 ft. 4 in.
2. History of Forced Marching.—A history of forced marching was obtained in 50%. In 10% the condition arose following prolonged marching—i.e., marching at normal rate but for a longer period during manœuvres; 10% were in mechanized sections.
3. Abnormalities of Feet (e.g., first-degree flat-foot, hallux valgus, pes cavus, etc.).—With one exception, none of these men suffered from any foot deformity.
4. Boots.—It was thought that a new issue of Army boots which might be unduly stiff at the back (the leg or quarter) might be the cause. The boots had been in use for a period of three to eighteen months.
5. Effect of Gaiters on Shape of Boot.—All the men wore the webbing gaiters. In every case a constricting ring was formed on the boot by the lower strap of the gaiters being pulled tight. In this way a small ridge is formed at the back of the boot which causes slight pressure on the tendo Achillis. Slight jarring, as would occur in ordinary marching, between the tendon and this ridge seems to be the chief cause of the tenosynovitis.

The theory that gaiters are the causative factor is supported by the fact that (a) the wearing of light shoes relieves the condition, but that it recurs on resuming boots and gaiters; (b) gaiters wear out at the points of the friction at the heel and over the lace-holes of the boot. Tenosynovitis of the tibialis anterior is often associated with the condition in the Achilles tendon.

A looser-fitting gaiter is required that will not cause a constricting ring on the boot, so avoiding abnormal pressure on the Achilles tendon. Most men wear a gaiter which is so tight-fitting that there is no overlap, and the gaiters bulge at the side, leaving a wide gap. Leather gaiters appear to be much looser, and ride easier on the foot. Larger gaiters or leather gaiters will prevent this condition arising, except occasionally.

The following lines of treatment have been adopted: (1) Rest and the use of a counter-irritant—e.g., Scott's dressing. Most cases clear in five to seven days, but about 20% are more resistant to treatment. (2) Infiltration of the tendon sheath and surrounding subcutaneous tissue with 2% novocain. Three injections each of 5 c.cm. are given on alternate days. If there is no improvement the foot has to be immobilized in plaster-of-Paris for four to six weeks.

A. A. WILLIAMS,
Captain, R.A.M.C.

Local Arrangements under the Cancer Act

Rather more than a year ago the Minister of Health informed local authorities of his decision to extend to March 31, 1942, the period during which they may submit their arrangements under the Cancer Act, 1939. The Minister recognizes that in general it is not possible for local authorities to make complete arrangements under the Act at the present time, and in Circular 2469, dated August 30, 1941, he extends the period for a further twelve months, while urging those who have not already done so to submit, as soon as possible, interim instalments pending formulation of more complete schemes. Local authorities should exclude from such interim arrangements the erection of new buildings, elaborate extensions to existing buildings, or the provision of costly new equipment. Much could, however, be done even under present wartime conditions by extending the facilities for diagnosis and treatment that now exist. Conditions in some of the specially vulnerable towns may be reducing or impeding the hospital treatment facilities available to sufferers from cancer, who may thus be precluded from obtaining hospital treatment which might be likely to benefit them. To counteract this the Minister is endeavouring to arrange, where practicable, for cancer treatment centres to be set up at certain of the hospitals in the Emergency Hospital Scheme outside the towns which they would serve. These centres would be a temporary and emergency provision to meet the exceptional conditions in these towns.

Reviews

THE AVITAMINOSES

The Avitaminoses: The Chemical, Clinical and Pathological Aspects of the Vitamin Deficiency Diseases. Second edition. By Walter H. Eddy, Ph.D., and Gilbert Dallhoff, M.D. (Pp. 519; illustrated. 25s.) London: Baillière, Tindall and Cox. 1941.

Since the publication of the first edition of *The Avitaminoses* certain vitamins have become available in pure form, and some have even been synthesized. This has led to the treatment of patients with the pure products, and much information has been acquired about deficiency diseases generally. The authors of this book have gallantly tackled the very difficult problem of sorting out the evidence which has accumulated during the last few years, for the information available is mostly the result of observation (no controls), not of experimentation (performed with controls). Their main conclusions, emphasized time after time throughout the book, are that a deficiency of one vitamin does not in general produce one specific lesion but a number of lesions which are not all specific to the vitamin in question, and, moreover, that most patients suffering from a deficiency of one vitamin are also suffering from deficiencies of several others. They also show clearly that the picture produced by a severe deficiency is not merely a more pronounced picture than that produced by a partial deficiency but a more complicated one altogether.

In connexion with the vitamin values of foods it would have been useful to have a short account of the need for and use of international standards of reference until the time when pure preparations should be available for comparisons in determinations of the vitamin contents of foods. It is a pity even to mention the obsolete units which were at best a temporary makeshift until international standards and units could be adopted. Vitamin B₁ (p. 6) is not a filtrate factor but an eluate factor from liver extracts, and pantothenic acid was the first factor (there may be others) identified in liver and yeast filtrates. But apart from various minor inaccuracies this is a valuable book of reference for all who are interested in deficiency diseases, and particularly for those (such as our own general practitioners) who may have to diagnose cases of partial deficiency in their daily rounds. The book contains 41 excellent plates from photographs of patients or morphological sections of deranged tissues.

GASTRIC OPERATIONS

Technique of Gastric Operations. By Rodney Maingot. F.R.C.S. Oxford Medical Publications. (Pp. 240. 15s. net.) London: Oxford University Press. 1941.

Mr. Rodney Maingot has produced a very readable and well-illustrated book of convenient size dedicated to a list of sixty-two students from the London Hospital who because of the war were transferred to the Southend Hospital for part of their clinical training. We hope, however, with all due respect to Mr. Maingot, that medical students will not spend time on memorizing the contents of a work such as this, which admirably deals with technical details important to the gastric surgeon but, we hope, as yet not within the visual range of the undergraduate student, who, faced with the extensive curriculum of to-day, is likely to be in real danger of missing the wood for the trees. The book has not the advantage of a historical introduction, which might have given it some value to the student, who will surely tend to be confused by the many variations in technique to which names of different surgeons are attached.

At a time when paper shortage is acute, when we are exhorted to use old envelopes again and again and save every scrap of waste, when our weekly medical journals are much reduced in size, so that topical and original productions have to be curtailed or at least delayed, it is rather strange that a textbook on technique unconnected with war surgery should appear in large print and handsome binding. More especially is this so when it is realized that most of the matter it contains can be found in the very recently published work on abdominal operations by the same author (reviewed in this *Journal* on May 31, 1941, p. 819) and in the many editions of textbooks we already possess.

It is probably true to say that there is nothing new in the book; it is certainly an expression of experienced opinion, but diluted with descriptions of the procedures of many others so that at times it is a little difficult to seek out the author's own point of view. Of total gastrectomy we are told that records in British literature are scanty but that Joll has performed twelve, Dickson Wright eleven, Walton eight, and Gordon-Taylor six. No references are given, however, and the figures of Grey Turner, Devine, and others with well-known experience of this operation are not mentioned. Coming to the types of gastric resection we find the statement, "It would appear immaterial on physiological grounds whether the cut end of the stomach is anastomosed to the duodenum or jejunum"; but surely there can be no refuting the fact that the proximal end of the duodenum is the normal receptacle for gastric contents and that this constitutes the great merit of the Billroth I type of operation.

This book may be summed up as a clearly written account of operations on the stomach practised at the present time by many surgeons, including the author. It is a far from complete account, as no doubt the author would be the first to admit, but at the same time it is in our opinion too technical for the undergraduate student. Its appeal should be to the young surgeon beginning his hospital work, but we hope with enough judgment not to be misled into becoming too ardent a gastrectomist.

SCIENTIFIC TERMS IN FRENCH

French-English Science Dictionary for Students in Agricultural, Biological, and Physical Sciences. By Louis DE VRIES. (Pp. 546. 24s. 6d.) London: McGraw-Hill Publishing Co., Ltd.

This dictionary, compiled by the professor of modern languages at Iowa State College, gives English equivalents for 43,000 French words. It has been compiled for students in biology and physics, and although under both these headings a large number of medical terms come in, it is not, and does not pretend to be, a medical dictionary. Many scientific terms are the same, or practically the same, in French as in English. Words like "hormone" and "vitamin," for example, are the same. Sixty words with the prefix "micro" and fifty with the prefix "photo" are almost identical in both languages, but it is useful to have them included, otherwise the student would neglect them, whereas now he has only to turn to Webster or Murray for further definitions. A list of about 700 abbreviations is appended to this volume. Abbreviation is a strong point with the French. Thus their small "t" may stand for time, temperature, revolutions (*ours*), metric tons, and volume, among other things, and their small "p" for weight, power, pulse, or page. It is interesting to notice the quite considerable number of words for which the French language is indebted to the English. One of these is "guinée," which, as it is the standard of professional remuneration, probably deserves inclusion in a science dictionary.

NEUROLOGICAL LOCALIZATION

Compendium of Regional Diagnosis in Lesions of the Brain and Spinal Cord. A Concise Introduction to the Principles of Localization of Diseases and Injuries of the Nervous System. By Robert Bing, Professor of Neurology, University of Basle, Switzerland. Translated and edited by Webb Haymaker. Eleventh edition. (Pp. 292; illustrated. 25s. net.) London: Henry Kimpton. 1940.

This translation of a work which has been justly popular on the Continent for the past thirty years will be welcome to students and practitioners on both sides of the Atlantic. Professor Bing here collects neurological data and arranges them with a view to the anatomical localization of the responsible lesions. Neuro-anatomy and clinical disturbances are thus correlated and set out in a way that greatly aids diagnosis. The present English edition preserves the form of the original text, its numerous excellent illustrations and diagrams being supplemented by radiographs supplied by Dr. H. C. Naffziger. The chapters are topographically arranged, and in each region the normal anatomy is first described, with special emphasis on the paths of conduction, followed by a section dealing with the symptomatology of lesions in the region. All these sections are lucidly written and admirably illustrated. The text has been brought up to date by a series of editorial footnotes. While these might profitably have been introduced in small type into the text they are not numerous enough to be a burden to the reader.

Notes on Books

Colonel C. ARTHUR WEBSTER has written a booklet of sixteen pages, under the title of *Fighting Fit*, which is full of useful hints on hygiene for the soldier. It is clearly and attractively written and can be read in a few minutes. In the hands of the soldier such a booklet should play a useful part in maintaining morale and keeping the men up to proper hygienic pitch. It was printed for private circulation, but a few copies are available, and application should be made to the author, H.Q., 4th A.A. Division, c/o G.P.O., Preston.

It is now thirteen years since we first commended to the notice of our readers a manual of birth control entitled *Parenthood: Design or Accident?* by a medical man writing under the pseudonym MICHAEL FIELDING, with a preface by Mr. H. G. Wells. This booklet was reprinted many times to meet a constant and well-merited demand, and revised editions came out in 1930 and 1934. The author's identity has long been an open secret in well-informed circles both within and outside the profession. He has once again brought the text up to date for a fourth edition, which is published by Williams and Norgate at 2s. 6d. (with cloth cover 3s. 6d.). The contraceptive methods taught by British and American authorities are described, with emphasis on some small but important modifications recently made in established methods and on new devices and expedients which have resulted from the investigations of the past few years.

Dr. ROY R. KRACKE'S *Textbook of Clinical Pathology*, which was published in 1938, now appears in a second edition under the joint authorship of Kracke and Francis P. Parker, with fourteen contributors in all. The defects consequent on multiple authorship which we criticized in the original edition have been remedied by rearrangement and better co-ordination, and, in particular, methods of general bacteriological examination are now more adequately described. The increase in size, amounting to nearly 200 pages, is due also to the introduction of much new material, and the range of diagnostic tests now covered is wide, although there are still some peculiar omissions, such as the test for occult blood in faeces, and the space-allocation in relation to the importance of the subject varies. The book is well illustrated, and for many purposes will be found a valuable guide. It is published at 33s. by the Williams and Wilkins Company.

LONDON

SATURDAY SEPTEMBER 13 1941

TRAUMATIC SHOCK—PAST, PRESENT, AND FUTURE

At the end of the last war fairly general agreement had been reached that traumatic shock consisted of two separate entities : primary shock, developing early from a supposedly neurogenic cause ; and secondary shock, developing late as a consequence of absorption from the injured tissues of substances resembling histamine in having a noxious effect on the capillaries generally. Little remained except to round off the evidence in some particulars and to settle the vexed question whether transfusion should or should not be employed in treatment. With the arrival of the more leisurely years of peace, the animal experiments on which the theory of traumatic toxæmia was chiefly based were repeated and the evidence crumbled away. Persistent inquiry failed to reveal any toxic substance in blood returning from injured tissues, and careful experiment showed that circulatory failure developing in animals after crushing the legs could be largely accounted for by the amount of blood and plasma lost into the swollen limbs. At the outbreak of the present war it became urgently necessary to re-examine *ab initio* the question of traumatic shock from the clinical point of view. Several questions demanded an answer. What do we mean by shock? Is it an entity or does it comprise several distinct conditions? What are the initiating and contributory factors and how can they be prevented or combated? Information relevant to these questions was collected in the last war and issued in M.R.C. Reports 25 to 27, and in this war is to be found in communications from the Army Blood Transfusion Service,¹ from the Hammersmith workers,² and in our last two issues from Grant and Reeve,³ who have analysed 100 case records submitted to the M.R.C. Committee on Traumatic Shock.

Shock is usually defined by a description. But descriptions are so varied that no one would satisfy all who use the term. Traumatic shock is in general used to denote any generalized disturbance in the function of the body following in a short space of time a more or less localized injury. It may mean no more than the effects of fright, but is more generally used to denote a grave disturbance often ending in death. It is becoming clear that the term "shock" may cover a multitude of conditions, and it is now known that more than one condition may be included in secondary shock. Thus attention has been drawn elsewhere to fat embolism⁴ and in this *Journal*⁵ to curious disturbances in renal function and plasma electrolytes after crush injuries.

Although these are relatively uncommon conditions they serve to illustrate the fallacy of regarding even so-called secondary shock as a clinical entity.

Because the meaning of the word is uncertain, and because it may convey a false sense of unity, Grant and Reeve do not use the term "shock," remaining on safer ground by describing and classifying reactions to injury. They divide their cases into three groups according to whether, on the first examination, the blood pressure is high, normal, or low, the third group being subdivided into those with slow, normal, or fast pulses. Although, as they point out, the data are too meagre to allow final conclusion, yet it seems that the type of reaction is determined, among other things, by severity of injury, by the amount of blood lost, by the time after injury when the patient is received, and by the patient's age. Groups 2 and 3 apparently represent successive stages in the response to injury and loss of blood, while the subdivisions of Group 3 are partly determined by age. The hypertensive reaction is more obscure, but Fraser and Cowell⁶ found it particularly common in wounds involving the ventricles of the brain.

At the outset of this war there were still some surgeons who had scant regard for the value of transfusion in the severely injured. Though there are some who still maintain this attitude, all serious observers are agreed that transfusion, provided it is instituted early enough and is given in adequate amounts, is a most important, perhaps the most important, measure in resuscitation. The paper by Grant and Reeve fully bears this out. In determining the need for transfusion they regard the severity of the injury and of the loss of blood as the most important guides, since the blood pressure and pulse rate may be maintained precariously and for only a short time. The complete failure of the pulse as a guide to the general condition is to be emphasized, for many injured patients still go through the whole period of their management without record of blood pressure ; it is time this lamentable practice ceased. A second therapeutic point which Grant and Reeve emphasize is the need for operation as soon as resuscitation has been adequately carried out. It is unfortunately true that many surgeons still believe that the most important factor in combating shock is the lapse of time, and many lives are wasted because of the failure to advance by adequate transfusion the time when operation becomes safe.

There is still ample scope for improvement in the treatment of the injured. Of the 100 cases recorded at least forty-four patients died. In many of these cases death could be accounted for satisfactorily by the nature of the injuries ; in others it was due to inadequate transfusion, anaesthesia, or infection. But in eight the cause of death remained obscure. This is a high proportion, and it may serve to bring the reader sharply back to the question of what are the causes of the conditions lumped together as shock. We do not know. We know that in many, perhaps in most, haemorrhage either external or internal is a chief factor, and we believe that pain and exposure often contribute. Fat embolism and the crush syndrome stand out as clear examples of disturbances we may hope to understand when further

¹ *Lancet*, 1941, 1, 99.² *British Medical Journal*, 1941, 1, 427 et seq.³ *Ibid.*, 1941, 2, 293, 329, 332.⁴ *Lancet*, 1941, 1, 135.⁵ *Ibid.*, 502.⁶ *M.R.C. Report 25, 1941, p. 55.*

work has been done. Infection also plays its part in some instances. But when all the factors are considered and integrated there remain patients who die without our knowing why. This knowledge will come only as a consequence of patient and intelligent observation of injured people; in a separate memorandum in our last issue Grant outlines some observations that are needed. The question is urgent, and it is to be hoped that some of those dealing with accident cases will avail themselves of their opportunities and help to elucidate once and for all the mystery of so-called shock.

DOMESTIC WATER SUPPLIES IN WAR

The fall in the incidence of the enteric fevers in recent years has been variously attributed—possibly in accordance with the predilection of the individual—to improved sanitation, increased purity of water supplies, and, particularly in the Army, to protective inoculation. The Annual Report on the Health of the Army in India for the year 1939 (vol. 2, part 1, paragraphs 12 and 13) throws considerable light on the subject. The incidence of enteric among the troops in India, expressed as a ratio per thousand, averaged 1.2 during the period 1936-9, compared with 3.3 during the period 1919-28, and since 1929 the tendency has been towards a slight but progressive decline with only an occasional minor setback. That the diminished incidence has not been due to improvements in general sanitation is strongly indicated by a comparison with the incidence of the dysenteries, a disease group essentially associated with insanitary conditions. The incidence of this group has shown an almost steady rise since 1932, which is described as "an entirely different and unsatisfactory state of affairs." The facts presented, therefore, appear to justify the following comment, also extracted from the report: "Considering the disease was rife in the surrounding villages we must conclude that inoculation and water treatment are the causes and our safeguard, and that it is not due to improved sanitation (other than water)." Inoculation played no part in the decline in enteric fever in England or the elimination of cholera which took place towards the end of the nineteenth century, following closely upon an energetic campaign and legislation for increasing the purity of water supplies. The continued but more gradual decline in enteric which has taken place during the twentieth century may be attributable in part to an awakening sanitary conscience, but it is reasonable to believe that it has been greatly contributed to by a gradual fall in the number of carriers, since this reservoir of infection is no longer frequently reinforced by water-borne epidemics. Knowledge of these matters is not exact enough to permit of dogmatism, but there can be little doubt that our first line of defence against a serious recrudescence of enteric is the maintenance of the purity of domestic water supplies.

The prevention and the suppression of water-borne disease are comparatively simple matters in times of peace. The case is very different when we are at war. At such times agencies directly or indirectly attributable to enemy action may counteract the most elaborate safe-

guards which water undertakings can provide. This has already been the experience of more than one of our cities. The epidemiologist is well aware that the establishment of epidemic conditions depends upon the connecting up of a number of links, and that our immunity up to the present has been due to the absence of some essential link or links in the chain of infection. In view of the comparatively slight incidence of diseases of the enteric group during the past decade, it is not unreasonable to suppose that one limiting factor has been the paucity of the specific bacteria in sewage. It is true that one cannot demonstrate the presence of these organisms in the effluents from many sewage works. It is equally true that they can be recovered regularly from sewage effluents derived from towns in which there has been no epidemic for many years. At the best estimate the potential danger is therefore constantly present, despite past experience.

The substance of the matter is not whether this potential danger exists, for its existence is already a well-established fact, but how far it may become a real danger to the health and to the morale of the country. To appreciate this it is necessary to visualize the possible results of a first epidemic of typhoid fever. A number of persons would suffer from the disease; an additional number would become infected but would have so mild an attack that they would not seek medical advice, or would not be ill at all. Those in each group would, for varying periods, become infective. The paucity of the specific organisms in sewage, which may have been the decisive factor in our past immunity, would no longer exist in the locality infected, and a travelling reservoir of infection would be created which might disseminate the germs in other localities. Each succeeding epidemic would increase the probability of another and larger one, and this probability might, at any time, be transformed into reality by circumstances beyond the control of those primarily responsible for the purity of our water supplies.

Those of our cities which have been the object of indiscriminate bombing have been exposed to various risks which differ widely in character. The possibility of epidemic disease resulting from overcrowding and poor ventilation in air-raid shelters and the serious effect this might have upon the morale of the people and the war effort of the country are obvious. The public, however, is hardly conscious of the grave consequences of water-borne disease. The Croydon epidemic has been forgotten or is not associated with the potentialities of war. The public is protected against the risks of water-borne disease by the unremitting care of the water undertakings throughout the country. They have proved their worth, but their widespread network of machinery and services has no immunity against indiscriminate bombardment. The enormous demands made upon their services for fire-fighting were not anticipated before the war, and their capacity, already strained, may be limited by war damage. Gaps in their defensive organization have been and will be created, and it is of the utmost importance to consider what reserve stands behind them to fill those gaps. The purification of water by individuals in their homes might provide an effective second line of defence against the

pollution of piped supplies, but such endeavours as have been made to educate the people in this matter have met with limited success. After heavy bombardment it is often difficult or impossible to boil water owing to interruption of the gas and electricity supplies, and simple chemical methods of purification which could provide a high degree of protection are unlikely to be widely used in the absence of any co-ordinated scheme for the education of the public and the provision of materials on the scale of that adopted for defence against poison gas. In the existing state of knowledge only a limited degree of protection could thus be expected from any measure which might depend upon the individual if left to his own devices, and we must therefore consider our last line of defence. Should there be good reason to fear an epidemic of enteric fever the surest means of prevention would undoubtedly be the intelligent use of preventive inoculation. Once decided upon this would have to be carried out without delay, and a high degree of success could be achieved only were it done under compulsion. The argument against this might well be overwhelming, and, if the risk were widespread, the performance of inoculation in the time available might be very difficult. We are thus driven back upon purification of water by the individual, and have to consider how the highest degree of protection can be secured in this way. Plans must be carefully worked out in advance, sufficient materials must be available, and the public must be educated in their use. We cannot afford to rely upon last-minute improvisation.

One point needs emphasis—the effectiveness of any precautions which may lie behind the water undertakings is limited, and theirs must always remain the first line of defence. This fact, however, provides no justification for not bringing each line up to its maximum efficiency, and this can be done only by planning and organizing on a uniform national scale. Lieut.-Colonel E. F. W. Mackenzie, Director of Water Examination to the Metropolitan Water Board, to make doubly sure of the efficiency of an already highly efficient undertaking, has recently asked the Board to set up a consultative committee which shall provide a closer link between himself, the medical profession, and the public health service in the Board's area. The chairman of this committee is Lord Horder, and it has on it representatives of the London School of Hygiene, the Society of Medical Officers of Health, and the Royal Sanitary Institute. Londoners may feel grateful that this additional care is being taken on their behalf.

DEATH FROM PLASMA TRANSFUSION

During the past year or so transfusions of various blood derivatives have been used in this country on a big scale. The number of such transfusions has run into thousands, and in addition larger quantities of fluid have been given to individual cases than have probably ever been used before. No authentic instance has, however, been recorded of a death thought to be immediately due to either plasma or serum. Dr. Frank Mayner has now recently reported¹ a disaster which he attributes to a plasma transfusion. A boy aged 4 came into hospital with unexplained severe

oedema of one week's duration after a "cold in the nose." The oedema was associated with a reduced urinary output. On examination the total plasma protein was 5.6 grammes per 100 c.cm., and in the urine, which was loaded with albumin, were red and white cells and hyaline, waxy, and granular casts. Many forms of treatment were tried, and after fresh-blood transfusion the patient was finally discharged with improvement in his oedema and with his urine free from albumin. After twenty-six days he returned with another respiratory infection and increased oedema. He was on this occasion transfused with 100 c.cm. of unfiltered saline citrate plasma prepared from the same donor. He died suddenly, becoming cyanotic and dyspnoeic during the transfusion. At necropsy microscopical examination showed subacute glomerular nephritis and multiple emboli of fibrin in the terminal pulmonary vessels and capillaries. Dr. Mayner concludes that the immediate cause of death was anaemia due to multiple emboli of fibrin in the capillary system of the lungs, and admits that this was possibly due to failure to use a filter during either preparation or administration of the plasma. In this country the bulk of the plasma used is filtered through a Seitz pad before issue, and is then passed through a coarser filter during administration, so that death from fibrin emboli is most unlikely to occur. Dr. Mayner also suggests that it may have been unwise to employ the same donor twice for the same patient, and quotes other cases of blood transfusion in which disastrous results have followed such an action. The case should not be regarded as in any way invalidating the use of plasma as a transfusion fluid in appropriate conditions, but does serve to emphasize the importance of adequate filtration.

CHEMICAL NATURE OF BACTERIAL ANTIGENS

In producing immunity with killed bacteria a number of substances must obviously be injected which have very little value in protecting the body against specific infections. If the chemical constitution of bacterial antigens could be systematically investigated it might be possible to isolate the essential antigens as chemical substances and thus to employ them for immunization; or, better still, synthesis of the essential antigens might well be attempted. Specific antigens could then be produced in unlimited quantities in the chemical laboratory. The first investigations on these lines were made by Boivin, Mesrobianu, and Mesrobianu¹ in 1933 on *Bacterium typhi-murium*, and were later continued by Raistrick and Topley² and others. A number of Gram-negative organisms have now been examined and their antigens isolated in a relatively pure condition without apparent change in their specific immunological properties. The two chief methods employed have been trichloroacetic acid extraction and tryptic digestion. Freeman and his colleagues³ have obtained the antigens of *Bact. typhosum* and *Bact. typhi-murium*, and have shown that by growth of the organisms in a synthetic medium various sources of contamination could be eliminated. In continuing this work they have examined the chemical constitution of *Bact. typhosum* Ty2 antigen, and find that on gentle hydrolysis it may be dissociated into a polysaccharide component, an insoluble polypeptide, a soluble nitrogenous component, and a small lipid component. The polysaccharide represents the O-specific hapten of the antigen and appears to be free from ketose, pentose, and uronic acid residue, but yields *D*-galactose, *D*-mannose, and *D*-glucose on hydrolysis. An identical polysaccharide has been prepared directly

¹ C. R. Soc. B.-J., Paris, 1933, 114, 307.
² Brit. J. exp. Path., 1934, 15, 113.
³ Biochem. J., 1940, 34, 307.

from the dried organisms by extraction with dilute acetic acid. The polypeptide component is insoluble in water but soluble in dilute alkalis. It contains 8.2% nitrogen, partly in the form of tyrosine and arginine units, while about 50% of the total nitrogen is liberated as amino-groups on acid hydrolysis. Two other components of the antigenic complex have also been isolated, but have not yet been studied in any great detail: one is a mixture of lipins, probably fatty acids with a phospholipin; the other, a soluble nitrogenous component as yet undetermined. Preliminary work on an O-antigenic strain of *Bact. typhi-murium* has yielded similar results to those on the typhoid bacterium, while in the case of *Bact. dysenteriae* (Shiga) Morgan and Partridge⁴ found that the antigen exists in the cell as a phospholipin-polysaccharide-polypeptide complex: the phospholipin component may be removed without destroying the antigenicity of the polysaccharide-polypeptide complex. These investigations naturally involve the use of relatively enormous masses of pathogenic bacteria and laborious large-scale chemical manipulations; they may, however, well constitute one of the most important advances in the treatment and prevention of bacterial disease.

PERFECT SIGHT WITHOUT GLASSES

A letter in this week's *Journal* from Dr. J. Parness draws attention to a statement recently broadcast by Dr. Julian Huxley on the practice of correcting visual defects without the use of glasses. Before condemning such a practice it would be as well to examine the evidence in support of it. There are a variety of methods based on hypotheses of varying degrees of tenacity. The system expounded by W. H. Bates in his *Cure of Imperfect Sight by Treatment without Glasses* (New York, 1920) has the advantage over competitive systems in that its principles are publicly stated. Bates holds that the refractive state is dynamic and is constantly changing. The changes in refraction are produced by the nerves and tissues of the extra-ocular muscles, the lens itself playing no part in accommodation. Defective vision is a psychic phenomenon, affection of the brain centres first disturbing the macula and then the whole retina. Treatment aims at inducing "cerebral relaxation," for when the mind is at rest vision is normal. In thirty years' work on refraction Bates found few people who could maintain "perfect sight" for more than a few minutes at a time, and he often saw "the refraction change half a dozen times or more in a second, the variation ranging all the way from twenty dioptries of myopia to normal." As no ophthalmologist has the necessary skill and speed to observe half a dozen or more changes in refraction in the space of a second ("blitz retinoscopy," as it might be called), no one is in a position to contradict this basic tenet of Bates. And ophthalmologists still cling to the theory, based upon physiological evidence, that accommodation is brought about by the changing curvature of the lens. Bates illustrates the influence of the mind on refraction by the effect of strain. Since strain implies mental unrest, changes in refraction occur in all conditions inducing such unrest. Thus "a patient 25 years old had no error of refraction when he looked at a blank wall without trying to see [i.e., under complete relaxation and total absence of strain]; but if he said he was 26, or someone else said he was 26, he became myopic [as shown by Bates's rapid retinoscopy]. The same thing happened when he stated or tried to imagine that he was 24. When he stated or remembered the truth his vision was normal, but when he stated or imagined an

error he had an error of refraction." There is also the case of the little girl who told a lie. The retinoscope revealed a change towards myopia the moment she replied "No" to the question, "Did you have an ice-cream?"; while she was giving truthful answers "the retinoscope indicated no error of refraction." This appears to be, so to say, a physical expression of the inward eye of conscience.

A queer assortment of evidence is brought forward to prove that the refractive changes in the eye are produced by the extra-ocular muscles. There is, for example, the "proof" that aphakic patients are able to read small type with distance glasses. That the daily experience of ophthalmologists is to the contrary is perhaps of some significance, though obviously not as significant as the few instances Bates records, for which, incidentally, perfectly good explanations are available, as anyone acquainted with the literature knows.⁵ There is, indeed, an extensive and controversial literature on the actual mechanism whereby the contour of the lens changes during accommodation; the facts themselves are not disputed—except by Bates, who produces experimental evidence that in the fish removal of the lens does not interfere with accommodation. The fish experiment is amply illustrated by photographs, but there is no reference to the fact that accommodation in the fish is different physiologically and anatomically from that of the mammal. Mammalian experiments, mainly on the rabbit and cat, are recorded, and here the rather startling point emerges that a nerve or muscle cut across and tied up again will carry an impulse on being tied, though physiologists would not expect any such result before days or weeks had elapsed. Mammalian anatomy is also illuminated in these experiments. Apparently the standard teaching that the cat is endowed with a superior oblique muscle is not correct. It should be added that this is only an incidental observation; but that pharmacologists err in believing that atropine acts only on unstriated muscle is part of the general argument, for Bates found that this drug will paralyse the extrinsic muscles which produce accommodation. One experiment, illustrated in Fig. 23, appears to show that the dead fish still has a living mind; its brain is pitied to induce relaxation.

The treatment based on these revolutionary observations aims at mental relaxation, and the pitied fish appears to be its prototype. The Bates system of treatment seems to have many devotees, and one incident may be worth noting. In 1931 the Republican Ministry of Public Health of Prussia warned against this method as a form of quackery,⁶ but in Hitlerite Germany a voluminous literature on the subject has spread the cult and there is apparently no lack of practitioners and patients.

INHERITANCE OF CEREBRAL DYSRHYTHMIA AND EPILEPSY

The work of Lennox, Gibbs, and Gibbs on the inheritance of dysrhythmia and epilepsy has already been discussed in these columns,⁷ but in a recent paper⁸ the authors supply further data and comment. Briefly, the electro-encephalograms of the close relatives of epileptics—parents, sibs, and children—were abnormal in 60% of cases, whereas those of relatives of a control group were abnormal in only 10%. The ratios are similar to those which would be found if dysrhythmia depended on a dominant gene, though whether the situation can be as simple as this is doubtful. Unquestionably in an undue proportion of cases of epilepsy both

⁵ *Amer. J. Ophthalm.*, 1921, 4, 286.

⁶ *Klin. Mbl. Augenheilk.*, 1931, 87, 514.

⁷ *British Medical Journal*, 1940, 2, 530.

⁸ *Arch. Neurol. Psychiat.*, Chicago, 1940, 44, 115.

⁴ *Biochem. J.*, 1940, 34, 169.

parents exhibit abnormal waves, so that if a single gene pair is concerned the effect of two abnormal genes must be greater than that of one alone. The authors state that of 13,262 close relatives of 2,130 sufferers from epilepsy 2.4% were epileptic. Thus, of persons with abnormal electroencephalograms only 1 in 20 or 25 is an actual epileptic. Examining twin evidence, the authors find that the combined data of several authors show that if epilepsy is present in one identical twin it is also present in the other in 70% of cases. This clearly indicates the influence of heredity, and also the importance of hereditary factors other than the simple determination of the dysrhythmia; it shows, too, that non-genetic factors help to determine the onset of clinical epilepsy. Lennox and his co-workers made electro-encephalograms of seven pairs of identical twins, and they also describe the results obtained in nine pairs of normal identical twins. The records, whether normal or abnormal, were closely similar for the twin pairs. In two cases there were differences, due to an acquired cortical lesion in one twin, though even here the basic rhythms were still similar. A history of fainting was encountered much more frequently among the relatives of epileptics than among the relatives of the controls. Of fourteen parents with such a history, twelve had abnormal electro-encephalograms, so that a history of fainting should be viewed with suspicion, since the attacks might in reality be mild seizures or precursors of seizures. The incidence of migraine was twice as high among the relatives of the epileptics as it was among the relatives of the controls, but the electro-encephalograms of migrainous parents were not more often abnormal than those of non-migrainous parents. Abnormal waves can on occasion be due to acquired causes. The case is quoted of a patient with adenoma of the islets of the pancreas with recurring periods of coma; the dysrhythmia disappeared a year after successful pancreatectomy. The authors conclude that in the absence of epilepsy abnormal rhythm is to some extent associated with other abnormalities. An undue proportion of problem children have abnormal waves; this is found too among schizophrenics; and there also seems to be an association with slight personality difficulties. Many persons with abnormal waves, however, appear to be normal in every respect. The authors suspect that degrees of abnormality are heritable but have not sufficient data for dogmatism. The incidence of abnormal waves is the same among the relatives of both "symptomatic" and "essential" epileptics. A practical eugenic point is that a person with cerebral dysrhythmia will be much less likely to have an epileptic child if he marries someone with normal brain waves.

INDUSTRIAL EYE INJURIES

A recent issue of the *Journal of the American Medical Association* (March 29, 1941) is devoted to industrial health, and contains four articles on ocular hygiene and industrial injuries. In many ways safety devices are more advanced in the U.S.A. than here, and there is certainly a greater awareness of the problems involved than is to be found in this country among both employers and employees. There are approximately 300,000 injuries to the eye in American industry each year, and their cost to the nation is in the region of \$60,000,000 annually. Intensive investigations have shown that the largest percentage of injuries occur in the machine-tool, foundry, and metal-products industries, and the loss of industrial efficiency in these basic industries at the present moment is of special significance. American records reveal an unexpectedly high incidence of visual defect in the industrial population as a whole.

an incidence that increases in the higher age groups. Admittedly there is no recognized standard of the necessary visual efficiency in the various industries, but such defects as 21% in visual acuity and 22% in muscle balance represent departures from a theoretical ideal and not necessarily from any valid standard of industrial efficiency. Systematic ophthalmic examination is recommended for the fairer assessment in cases of subsequent injury and for the selection of entrants to industry, with a view to reducing the incidence of accidents. These considerations emphasize that the use of goggles is not the beginning and end of preventive measures. None the less their value can hardly be exaggerated, and an educational campaign to popularize their use has apparently gone much further across the Atlantic than here. Certainly some of their safety slogans might well be adopted. They range from a poetical plea ("The light of the whole world died in a shower of sparks") to a concealed intimidation ("We once knew a man who could not see the need for wearing goggles—now he can't see the goggles").

TRIBUTE TO THE NURSING SERVICE

On the second anniversary of the outbreak of war the Overseas League gave a luncheon in honour of the "Nurses of the Empire," at which the principal speaker was Mr. Ernest Brown, M.P., Minister of Health. Mr. Brown said that various problems concerning the nursing profession were exercising him and his advisers, and as an indication of the importance they attached to their responsibility for nurses a separate Division had been created at the Ministry. Some steps had already been taken with regard to nurses' salaries (as recorded in our last issue at p. 344), and other matters were under consideration. So many demands were being made on the services of women that the vital need of the nursing services might possibly be overlooked, but wherever else there was a shortage there must be no shortage here. The Minister rightly insisted that it was not enough to have a sufficient total of nurses: what was required was to have the proper numbers at the right time and in the right place. He paid a glowing tribute to the work of nurses in the war, mentioning that of 32 George Medals awarded to women, nurses had received 17. The Army nurses had shared to the full the rigours of the first winter of war in France, the evacuation, and the stress of subsequent campaigns in Greece and elsewhere. He also referred to the help of nurses from the Dominions, 23 of whom were present at the luncheon, and of Red Cross workers from Allied countries. A further short speech was made by the matron of St. Thomas's Hospital, who had lent for the occasion the hospital's statue of Florence Nightingale, which, with a lamp burning in front of it, graced the head table. The luncheon was presided over by Sir Jocelyn Lucas, M.P., chairman of the Welcome Committee of the Overseas League, and among the guests were 130 matrons of hospitals in and around London, and nine nurses of the Harvard unit and six of the Wilson unit of the American Red Cross, together with four of the American Ambulance, Great Britain. Nurses who had received decorations for war service—or as many of them as could be persuaded to show themselves in public—were introduced to the gathering.

Sir Thomas Barlow celebrated his ninety-sixth birthday on September 4. Our readers will be pleased to know that he is still up and about and warmly appreciative of the good wishes of his admirers.

NORMAL AND PATHOLOGICAL SPECIMENS OF THE EAR, NOSE, AND THROAT IN THE ROYAL COLLEGE OF SURGEONS, LONDON

Although known and valued by E.N.T. workers, it has hardly been appreciated generally that London possessed perhaps the largest and most valuable collection of museum specimens illustrating the surgery of the ear, nose, and throat.

The Museum of the Royal College of Surgeons has been for many years assembling a select number of pathological, anatomical, and physiological specimens concerned with this specialty. One of its earliest gifts of normal anatomy was received when Toynbee presented his 300 specimens of the anatomy of the temporal bone. This addition was, later, greatly enriched when Arthur Cheatele handed over to the Museum his unrivalled series of sectioned temporal bones. The basis of the group of specimens related to rhinology was formed when the large collection of Onodi, from Budapest, was secured and presented by the otolaryngologists of this country. A valuable addition to the laryngological section of the Museum was made when V. E. Negus presented the specimens forming the foundation of his classic study on the comparative anatomy and physiology of the larynx. This last addition escaped damage when the Museum suffered considerably during London's bombardment by the Germans in May last.

Owing to the dispersal, for greater safety, of the specimens then undamaged it has not yet been possible for the College authorities to compile and publish a complete and accurate statement of the loss to medical science suffered by the Museum from enemy action. So far as specimens relating to E.N.T. are concerned the following information has been made known:

The catalogues of the Museum have been preserved, and it will be possible in the future to reproduce many specimens of normal anatomy from fresh material. The Onodi collection of the anatomy of the nose and accessory sinuses was heavily damaged, but about 95 specimens are intact and the others, being of normal human anatomy, can in time be replaced. The Toynbee and Cheatele collections have suffered even more severely. It is to be hoped that after the war young aural surgeons will be forthcoming to re-establish the Toynbee and Cheatele series of temporal bones. As to the pathological specimens, it is not possible to give a full report at present.

It is interesting and comforting to recall that the fourteen specimens of the anatomy of the paranasal sinuses, recently presented by the late Professor Hajek, are intact and complete. Professor Hajek was able to escape from Vienna about two years ago, and, with the generous help of American and British colleagues, he reached London with his devoted wife—a sister of the well-known dramatic writer Schnitzler. Here, by the help of his confreres, he was able to spend the last two years of his life in modest but comfortable conditions and in the enjoyment of the liberty which he so much appreciated. When he made his escape from Vienna, he was only allowed to bring with him, in money, the equivalent of ten shillings. He and his wife had to produce and leave behind their gold watches. The only pieces of gold they were allowed to export were their wedding rings. In spite of these difficulties he managed to bring away with him fourteen specimens of his valuable collection of rare irregularities of the anatomy of the nasal sinuses. The rest of his 150 specimens had to be left in Austria. These fourteen formed part of the specimens which he had shown, during nearly fifty years, in the practical classes which the American editors of his well-

known book¹ deservedly called "famous." They are illustrated in that work, which these translators of the English edition referred to as "a recognized classic."

As a token of his gratitude for his deliverance from the city where he had so long been one of the most esteemed teachers in the Faculty of Medicine, and for the welcome he had received in London, Hajek presented these valuable specimens to the Royal College of Surgeons through Mr. T. B. Layton, cataloguer of the Onodi Collection. It is one of life's ironies, and it is a comfort to remember, that when the German bombs were doing so much damage to the science and teaching of surgery in London they missed some of the most valuable specimens in oto-laryngology, which had come originally from Vienna and Budapest.

NEW ZEALAND

[FROM OUR CORRESPONDENT IN WELLINGTON]

Hospital Control: The Burden of Cost

The possibility of an alteration in representation on hospital boards in the event of the Government's finding a greater share of hospital costs has been mentioned by the Minister of Health in the course of a discussion with board members. Rating expenditure has become a matter of great concern to hospital boards, and various aspects of the position have been put to the Minister in the hope of relief. It has been represented to him that boards are not nearly so well off as had been expected as a result of the payment by the Health Department of six shillings per occupied bed per day under the Government Social Security Scheme. The rise in cost has completely wiped out any advantage (6s. as against 3s. in fees collected previously). A result is that increased levies have to be made on contributing local bodies. The Minister in reply has stated that officers of his Department are now working on a scheme to provide relief for some of the hospital boards. A great deal of thought, he said, must be given to the problem, and if the system is to be changed all the factors must be considered.

A National Problem

The Minister was asked if it was possible with any change in the system of rating that hospital board administration might be taken out of the hands of local bodies. He said in reply that he agreed with some form of local control because that was democracy; further, he added, if the Government was expected to find higher and higher amounts for hospitals there would need to be more State control. In his opinion, a large measure of departmental administration for the boards could be accomplished without any disservice to local bodies. The Minister said he realized that boards were alarmed at the increase in cost. In the matter of expenditure some boards had reached their peak and could not reasonably ask the ratepayers to find more money. When there was desperate need for accommodation with all room taxed heavily the time had come to recognize that it was not a local but a national problem and that it became necessary to rearrange the hospital rating system. The Minister explained that, so far as he knew, it was not intended when the Social Security Scheme was being prepared that the contribution of 6s. per head per day should be fixed and static for all time. The problems facing some boards would be looked at along with other proposals to meet a serious position. Regarding capital costs, where the burden on local ratepayers was such that they could not be asked to find the money locally, in his view the charge should become a national responsibility, but the actual details would require a lot of thought. It was also explained by the Minister, in discussing the matter with one of the hospital boards, that with capital expenditure the Government's contribution was £1 for £1, while for maintenance there was a fluctuating

amount, boards which were very highly rated being given a higher scale of subsidy. The Social Security contribution was an addition and the Social Security Scheme also found money for outpatient treatment and for maternity costs. It seems that the Government's contribution may go as high as 75%. It should be understood that an additional grant of 5s. per bed is made for soldier patients, which is, of course, far below the cost of treatment and maintenance.

The Last Word and the Last Straw

For many years the principle of hospital finance in New Zealand has been considered by optimistic people to be not only static but ideal and a model for other countries. The principle of this system has been in effect that the general Government taxation provided about half of the cost and the rest was paid by ratepayers. There seemed little moral obligation on patients under this system to pay for their maintenance and treatment out of their private purses, and only an amount of approximately 3s. a day per head was collected from patients. This amount seems very low seeing that any person, rich or poor, has the right to receive treatment in these tax- and rate-supported hospitals. The Social Security tax amounts to 1s. in the pound on all wages and incomes and commercial profits, and this proves quite insufficient. To make up the balance nearly four million pounds had to be drawn from general Government revenue last year. No medical practitioner service has been provided owing to opposition from doctors who decline to be "nationalized" under the conditions proposed by the Socialist Government. All medicines except proprietary medicine have lately been made free for both hospital and private patients, and all hospital treatment is free. The result of all this has been that the number of patients in hospitals throughout New Zealand has increased alarmingly, out of all proportion to any increase in population. Thus, State control has not been an unqualified blessing and has created new difficulties of a grave order, especially when the chief task of the country is the prosecution of the war effort. Any further increase in the huge burden of hospital costs will suggest to the minds of many people the time-honoured story of the last straw that broke the camel's back.

Correspondence

Penicillin

SIR,—Your annotation on penicillin (August 30, p. 310) is very welcome to me, who in 1929 discovered and named this very potent substance produced by a certain type of penicillium. It is true that all the work on this substance originated in the accidental contamination of a culture plate with a spore of this penicillium, and in my first paper on the subject a photograph appears of this culture plate. (Incidentally, this culture plate still exists.) I think, however, I can claim some merit in the discovery, as without a doubt the same mould has contaminated hundreds or thousands of culture plates and has merely been regarded as a nuisance.

There are many species of penicillium, and, at first, on the advice of a mycologist then attached to our laboratory at St. Mary's Hospital, it was referred to as *P. rubrum*. It has since, however, been examined by other experts in Europe and America, and the known species to which it has the closest affinity is *P. notatum*, although the type culture of *P. notatum* does not produce penicillin.

I do not think that you quite do me justice when you say that, although penicillin was used at St. Mary's and elsewhere as an ingredient of selective media, it "does not appear to have been considered as possibly useful from any other point of view." In my first paper on the subject in 1929 I made observations on its antiseptic properties against many species of bacteria, on its toxicity to leucocytes *in vitro*, and on its toxicity to animals. I showed that the simple unconcentrated culture could, even when diluted some 800 times, inhibit the growth of pyogenic cocci, while it was no more toxic to leucocytes or animals than the broth in which it was grown. I had previously, in 1924,

shown by the slide-cell technique that all the antiseptics in common use had a much greater inhibitory effect on leucocytes in human blood than they had on bacteria, and until I found penicillin there was not a chemical antiseptic which by this simple *in vitro* test could be considered as an antiseptic of the first class for the restriction of growth of bacteria in human tissues. This led me in my original paper in 1929 to allude to the possibility of the use of penicillin as an antiseptic, and paragraph 8 of the summary of this paper reads: "It is suggested that it may be an efficient antiseptic for application to, or injection into, areas infected with penicillin-sensitive microbes." In a later paper, on "Some Problems in the Use of Antiseptics," published in the *British Dental Journal* in 1931, I discussed the possibility of the use of penicillin as a surgical antiseptic and made the following statement: "Penicillin is valuable to us at present in the isolation of certain microbes, but it is quite likely that it, or a chemical of similar nature, will be used in the treatment of septic wounds."

These extracts from my papers show that wider uses for penicillin than selective culture media have been envisaged from the beginning, and the last quotation indicates that ten years ago I had concluded that the practical application of penicillin in surgery depended on the chemist who could isolate the active principle and manufacture synthetically this or an allied compound.

Prior to the second article cited (1931), a few tentative observations had been made on the effect of the local application of the unconcentrated culture to septic wounds (chiefly carbuncles and sinuses). Although the results were considered favourable there was no miraculous success. In those times septic wounds in the hospital wards were relatively uncommon, and it was not considered that the production of penicillin for the treatment of these was practicable, owing to the lability of the active principle in solution. The lability of the active principle is still a stumbling-block, but the Oxford workers have to some extent overcome it by extracting an impure active agent and keeping it in the dry state. This great advance has enabled a clinical trial to be made which has more than justified the suggestions I made ten or more years ago.

I have shown (*Proc. roy. Soc. Med.*, 1941) that dried penicillin, with which the Oxford workers kindly provided me, is many times more powerful than the most potent of the sulphonamide compounds. Penicillin does not appear to belong to the sulphonamide group, and if the active principle could be isolated in the pure state, and if its constitution could be ascertained, it would lead to the production of another series of chemotherapeutic agents which may well replace sulphanilamide and its derivatives in medical practice.—I am, etc.,

St. Mary's Hospital, W.2, Sept. 1.

ALEXANDER FLEMING.

Planning for Mental Health

SIR,—Some interesting points are raised by the report of the B.M.A. committee on the handling of problems of mental health and illness (August 23, p. 276). On the incidence of mental illness, for instance, one fallacy seems to be current, and from your note even the committee does not seem to have avoided it. It is said that "the incidence of mental illness is difficult to ascertain," and the witnesses apparently gave discrepant assessments and have not much helped the committee.

May I suggest the reasons for this apparent discrepancy. On analogy, compare mentally ill people with physically ill people. The physically ill fall roughly into two classes: those who are chronically or permanently ill and those (constituting the vast majority of normal or at any rate average people) who have intercurrent or occasional illnesses. Not one of us has had no physical ailment, serious or trivial, at some time or another; yet we do not consider ourselves as diseased. The nervously or mentally ill (the word "mental" has an unfortunate connotation in that to most people it implies insanity or psychosis—"mal-adjustment" would be a more suitable word) fall similarly into two classes. On the one hand are those who have become chronically neurotic or psychotic or who are constitutionally mental defectives, and on the other are the vast majority of us who at some time or another have had or will have nervous complaints and temporary maladjustments—that is, minor depressions, spells of acute anxiety, serious sexual, personal, marital, economic, or

other problems, or problems arising from somatic disease or accident:

One cannot legitimately speak of the incidence of mental illness (if by "mental" is not merely meant psychotic). One may, of course, speak of the incidence of certifiable lunacy or deficiency, but surely not of the maladjustments, which we all have at one time or another, just as we all have physical ailments sooner or later. It seems to me rather important to discard the impracticable concept of two classes of people: the mentally ill and the mentally well.

Psychological problems arise at every stage of our lives: the weaning of the infant from the breast and from infantile excretory habits; the weaning from the home when school demands it, the sexual problems of the adolescent, the young unmarried, those about to be married, and those recently married: marital problems and the weaning of the mother from her children when they must leave home; the problems of involution and bachelorhood; the problems of ageing and ill people, which are not sufficiently realized; the problems that arise during and after physical disease or accident. All these are minor problems when they first arise, but the physician who fails to make a distinction between those permanently ill and those mentally perplexed may fail to treat the latter. Problems which might easily be solved or prevented even by one or two interviews may graduate into chronic and permanent mental illness. To raise the question of the incidence of mental illness tends to confuse the problem by over-simplification. A multiplicity of factors are involved. The problem primarily is not one of treating neurotic people, but of treating the neurotic disturbances of the population at large.

The definitions of "psychotherapist" and "psychiatrist" are neither clear nor illuminating. In practice, the former seems to be applied to those who treat the psychoneurotics and the latter to those who diagnose the psychotics. The term "neuropsychiatrist" might be a better one, because one cannot help one type of maladjustment without experience and knowledge of the others. Moreover, the medical psychologist must have some skill in the somatic aspect of disease, especially in neurology. The "pure" neurologist who disdains psychiatry need not, of course, have this wider knowledge: unlike the neuropsychiatrist he diagnoses often, treats much, but cures seldom.

I suggest that psychological medicine should be integrated with the rest of medicine and not be "psychically isolated" from it. The basic medical syllabus should include side by side: medicine, surgery, obstetrics, and psychological medicine. The doctor—whatever his function or specialty—is expected to know something of minor medicine, minor surgery, and even of minor obstetrics—and to know when to refer the major cases to the specialist. As there is a psychological factor in every ailment, he must not be allowed to shirk his responsibilities where the mentality and problems of the patient influence—or can influence—his trouble.

Many doctors even now are apt to deride the medical psychologist: accusing him of theorizing and of poor results, and of disagreeing within his own tribe. If they would only spend one morning in a busy out-patient psychiatric clinic they would realize, first, that competent psychiatrists differ no more in their actual practice than one general practitioner differs from another. All of us have our pet foibles and fads and skills: practitioners of widely different schools treat cases in very much the same way. And the good psychiatrist wisely commits himself to no theoretical school; the warring of psychological sects has now largely ceased, except among the verbally minded. Secondly, he would realize that it is very easy to get good results where the general practitioner sends a case in time; and that even in neurotics of long standing the results can be good. But a common fallacy must be realized: it is no more possible to "cure" a constitutional nervous illness than it is to cure a hereditary physical illness. It can be alleviated so that life is tolerable, unless the case is sent far too late. For some reason the non-psychiatrist demands of the psychiatrist a radical cure where he would not think of demanding it of himself, and sends his lunatics for cure and is righteously indignant when this is not possible.

My points may not all have been immediately relevant to the committee's report, but that they can have some bearing on the medical profession's reaction to that report I sincerely hope.—I am, etc.,

Bridge of Earn, Perth, Aug. 23.

HENRY HARRIS.

SIR.—The B.M.A. Committee's report on this subject, as epitomized in your issue of August 23 (p. 276), gives one furious to think. Is it not clear that unless this topic be considered in its widest bearings, mental and moral "inadequacy" will continue to spread not only in this country but all over the world? beg to touch upon one important aspect which has apparently not come under the purview of the committee in question. May not the increasing psychological ill-health with which the present generation is faced be related to the peculiar sociological problem which is also now daily pressing itself on our notice—namely, the war? In short, is not Western civilization now breaking up by a process strongly suggestive of suicide; and, if that be so, should we not consider the psychological break-up merely one aspect of the general process—complicated, of course, by the usual phenomena of vicious circles, effects becoming themselves causes and so leading to ever more deeply growing confusion? Under such circumstances how should we expect to find sanity ruling or extending its sway in the affairs of daily life? *Quia custodiet ipsos custodes?* The time will come for our pundits to start teaching "mental and moral hygiene" when they have themselves arrived at general agreement on its first principles (as distinguished from some of its symptoms).

I will end with a single practical suggestion. I personally believe the source of the whole trouble to be the break-up of family and local life. Ever-increasing centralization, with its inevitable accompaniment of bureaucracy—that is, rule by the impersonal machine—is not only playing ducks-and-drakes with our Western civilization; it is actually promoting insanity.—I am, etc.,

Inverness, Aug. 26.

A. J. BROCK.

Bacteria from Wounds Enclosed in Plaster

SIR.—In the *Journal* of August 23 (p. 268) Dr. H. L. de Waal describes an ingenious method of taking bacteriological samples from wounds enclosed in plaster, and severely criticizes the method described by us a short time ago (*Journal*, 1941, 1, 877). We should hesitate to criticize Dr. de Waal's method without a thorough trial had he not done this to us. If he had tried our method and our apparatus he would have found that oedema does not occur; nor does granulation tissue grow into the base of the cylinder. But apart from any actual trial, since the base of the apparatus lies flush with the inner surface of the plaster and is completely closed it is difficult to see why oedema should occur and easy to see that penetration by granulation tissue is impossible. It seems that the type of window he describes as suffering from these defects is not ours, but one previously used by himself and discarded. When the window is properly applied samples obtained through it are indistinguishable from those obtained from other parts of the wound. Many of our observations were made on wounds without windows. Their flora, observed at changes of plaster, did not appear to differ from those with windows; nor did the removal of a window from a given wound or its insertion appear to influence the quality of the samples obtained. We conclude from this evidence that the bacterial flora at the base of the cylinder is representative of that in other parts of the wound.

As to his recommended procedure, we see many virtues in it and some possible vices, the reality of which could only be proved or disproved by experience. For example, the thread in being withdrawn has to be dragged, according to the diagram, across an intact skin surface which would presumably be coated with discharge in which irrelevant saprophytes would be pululating. Incidentally, this dragging might well be considered surgically undesirable as disturbing granulation tissue, especially in the early stages of healing. Again, the thread itself, like a dressing, constitutes a system of minute stationary foci of decomposing discharge, and may well be rich in microbes which are scanty on the actual wound surface. We found in the early stages of our work that if gauze dressings were put under the window our samples from the outside of the dressing were not representative, and we corrected this in the later part of the research.

As to the chances of secondary infection through the two types of window, Dr. de Waal alleges that ours is risky and implies that his is not. In theory there is not much to choose between the two in this respect, though we prefer ours: but in

practice we have published evidence that ours does not give this trouble, whereas his claims are unembarrassed by any documentation.—We are, etc.,

A. D. GARDNER.
J. C. SCOTT.

Puerperal Tetanus

SIR,—I am interested in the paper on puerperal tetanus by Drs. Bruce Maclean and P. Challen (August 30, p. 302). In the case of puerperal tetanus which I described in the *Chinese Medical Journal* (1928) I stated I could not find any record of a similar case in China, but tetanus neonatorum was very common in parts of the province (Fukien, South China), due, I am sure, to the custom of the native midwives using earth to dress the cord. The infant mortality was, of course, extremely high.

I hoped my report might bring records of other cases in different parts of China, but only one reply came in from South China later. In South India I had a case of severe puerperal tetanus brought in on the fifteenth day of the puerperium. The woman had been delivered by a native midwife.—I am, etc.,

Ipswich, Sept. 1.

L. H. H. BYRNE.

SIR,—Drs. Bruce Maclean and P. Challen, in their interesting report of this rare complication, suggest that the infection might have originated from the rectum or possibly from the perineal suture material. As the latter was silkworm gut they might be interested in the Tetanus Committee's report in the *Journal of Obstetrics and Gynaecology of the British Empire* for June, 1941, on the anaerobic infection of vulval pads, on the reinfection of cotton-wools and cellulose tissues after sterilization in manufacture, and on the difficulty of eliminating spore-bearing organisms unless an absolutely rigid technique of sterilization is followed. The committee's report gives some valuable information on the sterilization of all dressings, and paras. 2 to 5 (pp. 396-400) are of much general interest.—I am, etc.,

Minera, near Wrexham, Sept. 4.

R. OWEN-JONES, F.R.C.S.Ed.

Routine Radiography of Students' Chests

SIR,—I was interested to read the letter from the secretary of the British Medical Students' Association (August 23, p. 279), in which recognition is made of our scheme for the regular x-ray examination of our students' chests. This scheme has proved most successful in the detection of early cases of pulmonary tuberculosis, and hence, presumably, in the prevention of frank cases of the disease. It has been eagerly accepted by our students, and it is not surprising to find that there is now a demand for its general introduction at other schools.

There is, however, one point in Miss Tinker's letter which requires correction. The x-ray scheme as run at University College Hospital was conceived and originally established and financed entirely by this medical school out of its own funds. Hence, however, the Prophit investigation of the Royal College of Physicians was commenced, the two schemes have been run in co-operation, and we are very grateful for the assistance which we have received from the Prophit Scheme.

The routine x-ray examination of students' chests may prove to be the beginning of a wider organization of students' health services.—I am, etc.,

University College Hospital, London, W.C.1.

GWYNNE WILLIAMS,
Dean.

Recovery from Crush Syndrome

SIR,—Your annotation on recovery from crush syndrome (August 30, p. 311), in which my article on the same subject (*Journal*, August 9, p. 197) is mentioned, leads me to correct a misprint in the chart of the latter: "30 grammes sodium citrate" should have read "30 grains." I wish also to add the fact, interesting in view of the article by Longland and Murray (*Lancet*, 1941, 2, 158), that in my case the urine remained acid for twenty-three days after admission and for eleven days after the administration of citrate had begun. This observation and others were included in the original draft of my report, but were excluded from the final copy to satisfy the exigencies of space.—I am, etc.,

Carlisle, Lanarkshire, Aug. 31.

RONALD G. HENDERSON.

Rupture of the Drumhead as a Wartime Injury

SIR,—Points in Dr. A. B. Alexander's paper on "Rupture of the Drumhead as a Wartime Injury" (August 9, p. 195) aroused my special interest. He mentions that over 50% of cases due to blast injury seen by him were infected. A short time ago I had the opportunity of inspecting a considerable number of ruptured drumheads in naval personnel. Over 80% of these cases healed without infection. Those that failed to do so had either suffered immersion after reception of the blast injury, or had received drops in the ears previous to admission to hospital. Drops should never be inserted into a dry ear with a traumatic rupture of the membrana tympani. Unfortunately, this is not always realized, and drops are prescribed from a mistaken but praiseworthy desire to do something.—I am, etc.,

Aug. 24.

D. BROWN KELLY,
Surgeon Lieut., R.N.V.R.

Case of Shock from Burns

SIR,—Drs. R. T. Grant and E. B. Reeve (August 30, p. 293) describe examples of traumatic shock in which the blood pressure is raised, but in their nine cases the pulse rate remained comparatively slow, never rising above 92. A case of burn shock in which the blood pressure was high and the pulse rapid recently came to my notice and its features seem to be worth recording.

A pantry-maid aged 18 was admitted to hospital at 1.30 p.m., suffering from extensive second-degree burns of the back, thighs, and forearms. She was seen forty-five minutes after the accident, and appeared clinically to be severely shocked—pale, sweating, mentally alert, with a temperature of 97.2° F. and a pulse rate of 144. The blood pressure was 150/110. She was treated in the first instance by sodium bicarbonate compresses, morphine, and warmth. At 2.30 the blood pressure was still 150/110; at 4.0 it was 130/110 and the pulse 152; by 5.45 the blood pressure had dropped to 95/40; 900 c.cm. of plasma was then administered and the blood pressure rose to 130/90, the pulse rate being 128. At 8.0 the blood pressure had again dropped to 90/50; 450 c.cm. of plasma and 900 c.cm. of plasma-saline were given in thirty minutes and raised the blood pressure to 125/80. It was then considered that she was fit for treatment of the burnt areas, which was carried out under ether anaesthesia eight hours after admission.

The normal blood pressure, determined from the mean of several readings during convalescence, was 115/70.—I am, etc.,

Liverpool, Sept. 7.

WILLIAM M. BEATTIE, F.R.C.S.

Voluntary Hospitals

SIR,—Sir Frederick Menzies (September 6, p. 353) goes to the root of the matter in asking: "What are the particular virtues of the voluntary hospital system which are conspicuous by their absence in the municipal hospital system?" Your correspondent, Dr. E. Montuschi, on "Group Practice or Bureaucratic Medicine" (*Supplement*, September 6, p. 41) gets down to essentials also when he states that: "The last [national organizations] are concerned with broad issues of policy, the regional with the more concrete problems of organization, and the local with the living practice and execution of the demands for which the system came into being. For these demands are, in ultimate, the demands of human beings living diversely, in different places and in differing environments."

It is of importance that there should be some clear understanding of the difficulties confronting those who must soon face the problem of a reorganization of the health and hospital services of the nation. For the greater part of my life I have served in the dual capacity of a medical administrator—dealing with the concrete problems of organization—and as a practising physician (albeit a specialist) in intimate contact with personal demands of living human individuals. For the last two years I have observed with interest the working of what amounts to a voluntary hospital, uprooted and transplanted by the war, within the framework—indeed, the very walls—of the local authority hospital of which I still remain "in charge." After this experience I feel I may usefully attempt to give my answer to Sir Frederick Menzies's question.

One of the better features of the voluntary hospital is the feeling of independence and personal responsibility for their work and the welfare of their patients which the senior staff have and in consequence the loyalty which juniors accord them. Such a

not precluded by the municipal hospital organization and may be found, but its free existence is not securely provided for. On the other hand, I am equally sure that "problems of organization," more particularly between different hospitals or groups of hospitals, are more effectively secured in a municipal service. Those brought up in a voluntary hospital milieu are apt to be intolerant of the control which an "efficient organization" should exercise. This no doubt arises from a fear, not without some justification, that effective organization may mean only inefficient interference.

A satisfactory system, I believe, must ensure a clear-cut separation of the functions of the policy-making central powers, of the local organizing authority, and of the practising executive, and secure independence for each within its own field. Let me add that, while the functions of each should be distinct and separate, the working of the scheme will be helped by suitable individuals acting in more than a single sphere.—I am, etc..

St. Albans, Herts. Sept. 6.

W. J. T. KIMBER.

Remedy for Defective Sight

SIR.—In a recent radio programme of the series entitled "Any Questions" a question was submitted as to the possibility of remedying defective eyesight without the use of spectacles. In dealing with this question Prof. Huxley stated that there was such a treatment but he was unable to give details about it. In the next programme of "Any Questions" Prof. Huxley took occasion to make a special announcement to the effect that he had now ascertained that this form of treatment was practised in this country by . . . who had written a book on the subject entitled . . . and also by . . . who had written a book entitled . . .

One would wish to inquire whether this method of treatment has been approved by the leading ophthalmologists. Also whether it is to the advantage of the public to have this form of treatment propounded to them in this way.—I am, etc.,

Manchester, Aug. 11.

J. PARNES, M.B.

* Dr. Julian Huxley informs us that he had done no more than state that there were practitioners of these methods in this country (not mentioning any names), and that there were two books on the subject—namely, *Normal Sight without Glasses*, by Dr. W. D. Bates, and *Perfect Sight without Glasses*, by H. Benjamin. Dr. Huxley also tells us that he has personal knowledge of one case in which improvement of sight had been obtained in a patient treated for thirty years by other methods without success.—Ed., *B.M.J.*

The Services

NAVAL AWARD

In a *Supplement to the London Gazette* dated August 19 the name of Surgeon Commander Edward Heffernan, R.N., was misspelt. He has been awarded the O.B.E. for bravery and devotion to duty in boarding a burning merchantman during an enemy air attack.

MENTION IN DISPATCHES

Surgeon Lieut. Harry Winston Gothard, R.N.V.R., has been mentioned in dispatches for courage and devotion to duty when H.M.S. *Southampton* was lost.

EFFICIENCY DECORATION, TERRITORIAL ARMY

The Efficiency Decoration of the Territorial Army has been conferred on Colonel A. R. Laurie, Lieut.-Cols. D. W. E. Burridge, T. E. A. Carr, W. A. Ramsay, and A. B. Williamson, and Majors (Temporary Lieut.-Colonels) A. S. Pern and R. O. Townend, R.A.M.C. (T.A.).

Obituary

HERBERT SPENCER, M.D., LL.D., F.R.C.P.

Consulting Obstetric Physician, University College Hospital

The death of Dr. Herbert Spencer on August 28 breaks one more link between the *British Medical Journal* of former days and University College Hospital. Like T. W. P. Lawrence—pathologist, linguist, and anatomical draughtsman—he became acquainted there with Sir Dawson Williams, and formed a lifelong friendship with both. Many of his writings, obstetrical and historical, appeared first in these columns, and his wide and varied knowledge was always at the *Journal's* disposal for the benefit of readers. He had been a member of the Association for fifty years.

Herbert Ritchie Spencer was born on January 16, 1860, at Atherstone, in Warwickshire, the second son of Henry Spencer. He had a good classical grounding at Atherstone Grammar School and went on in 1879 to study medicine at University College, London, qualifying M.R.C.S.

and L.S.A. in 1883. A year later he gained honours in the Final M.B., B.S. examinations of London University, and proceeded to the M.D. in 1886. The foundations of his life-work were laid by Sir John Williams, then teaching at University College Hospital and at the height of his fame as an accoucheur. After holding the post of assistant in the midwifery department Spencer was elected assistant obstetric physician to the hospital in 1887. He was given the title of Professor of Obstetric Medicine by University College in 1893, and remained on the active staff until 1925. In the middle of that long period of service he held high office in his branch of the profession—President of the Section of Obstetrics and Gynaecology of the British Medical Association in 1905, President of the Obstetrical Society of London in 1907, and President of the Obstetrical and Gynaecological Section of the Royal Society of Medicine immediately after the amalgamation. He gave the Lettsomian Lectures before the Medical Society of London in 1920 and presided over that society three years later. In 1924 he was chosen as Lloyd Roberts Lecturer and took as his subject "The Renaissance of Midwifery," which he illustrated with a wealth of information about early books and their authors.

He became a Fellow of the Royal College of Physicians of London in 1899, was examiner in midwifery for four years, served on the Council of the College in 1917-19, and delivered the Harveian Oration in 1921 and the FitzPatrick Lectures in 1927. He had also examined in midwifery and diseases of women for the Universities of Oxford, Cambridge, and London. Academic distinctions of which he felt justly proud were honorary Fellowship of the American Gynaecological Society, of the Obstetrical Society of Edinburgh, and of the Società Medica Chirurgica di Bologna; honorary membership of the Société d'Obstétrique et de Gynécologie de Paris, and of the Société Belge de Gynécologie et d'Obstétrique; and an honorary doctorate of the University of Aberdeen.

Spencer revered the name of William Harvey and never lost an opportunity of paying homage to the man and his work. He took a keen interest in the project for restoring the tower of Hempstead Church in Essex, where Harvey's remains are deposited, and was from the beginning a member of the Harvey Memorial Committee. His Harveian Oration in 1921, the first to be delivered by an obstetrician for fifty years, dealt with "Harvey as Obstetric Physician and Gynaecologist," and came as a timely reminder that Harvey was the author not only of

an immortal book on the circulation of the blood but also of a great book on the reproduction of animals. How great and real was Harvey's knowledge of midwifery the Orator had no difficulty in proving. His FitzPatrick Lectures on *British Midwifery in the Seventeenth and Eighteenth Centuries* were the outcome of many years of research and laid before the profession a fine chapter of British scientific progress and discovery in the obstetric branch of medicine. Printed in book form soon after their delivery they stand as a permanent contribution to the history of medicine, with many curious sidelights on the old English obstetricians. In 1928 Spencer was elected President of the Section of the History of Medicine of the Royal Society of Medicine, and in 1929 he gave an address on medicine in the days of Shakespeare. His writings on the practical side of his specialty included books on *Caesarean Section*, and on *Tumours Complicating Pregnancy, Labour, and the Puerperium*, the latter being an amplification of his Lettsomian Lectures published serially in the *British Medical Journal*. Thirty years ago he shared with T. W. P. Lawrence the task of preparing a descriptive catalogue of the specimens illustrating gynaecology and obstetrics in the museum of University College Hospital. Among the good causes that appealed to his nature was the Royal Medical Benevolent Fund, of which he was a vice-president and member of the Committee of Management.

A man of large physique, with commanding eye and resonant voice, Herbert Spencer liked company and was a familiar figure at medical gatherings in London. His forthright speech proclaimed the firmness of his opinions. He read much and delighted in old books; travelled abroad and made a collection of lacquer ware and other objects of art; greatly enjoyed a day's shooting or fishing or bird study; and was a judge of wine and food. Advancing years and the coming of war cut him off from some of those pleasant pursuits, and the deaths of old friends one by one left him rather a lonely man, for his friendship, not lightly given, was very staunch. Our portrait, reproduced from a photograph by Lafayette, shows H. R. S. as many of us like best to think of him—in jocular mood.

We regret to announce the sudden death, which took place on August 27 in Kenya at the early age of 25, of Dr. DAVID HUGH MANSON-BAHR, second son of Sir Philip and Lady Manson-Bahr and grandson of the late Sir Patrick Manson. Hugh Manson-Bahr was educated at Rugby and Trinity College, Cambridge, and after taking his B.A. went on to the London Hospital. He qualified M.R.C.S., L.R.C.P. in 1940 and undertook the course at the London School of Hygiene and Tropical Medicine, obtaining the D.T.M.&H. early this year; also his Cambridge M.B., B.Ch. He entered the Colonial Service with the idea of serving eventually with the Colonial Forces in East Africa, but he was cut off within a few weeks of arriving in Kenya. He was good at all times and specially prominent at rugby football, playing for hospital and the United Hospitals team. He was fond of out-sport of every kind, and was a skilful and ardent falconer member of the Falconers' Club. His untimely death cuts off a career of much promise.

Medical News

The Right Hon. Sir Earle Page, G.C.M.G., M.B., Ch.M., Australian Minister of Commerce, has been appointed by his Government to come to London to establish personal Cabinet liaison between the United Kingdom Government and that of the Commonwealth.

An account of the Mental Health Report was published in the *Journal* of August 23. Copies of the report are obtainable from the Secretary of the Association, B.M.A. House, Tavistock Square, W.C.1, at the price of 6d.

A special luncheon in celebration of the twenty-first anniversary of the foundation of the Tavistock Clinic will be held on Monday, September 29, at Grosvenor House, Park Lane, at 12.30 for 1 p.m., under the patronage of H.R.H. the Duke of Kent. The wartime address of the clinic is Westfield College, Kidderpore Avenue, Hampstead, N.W.3.

The Council of Epsom College will shortly award St. Anne's Scholarships to girls attending Church of England schools. Candidates must be fully 9 and under 16 years of age, and must be orphan-daughters of medical men who have been in independent practice in England or Wales for not less than five years. The value of each scholarship is dependent upon the means of the applicant and the locality and fees of the school selected. The Conjoint Committee will in November next award a "Chalice" annuity of £32 per annum to a duly qualified medical man who, on account of old age, has been compelled to retire and who is in need. Forms of application for the scholarships and pension can be had from the Secretary's Office, Epsom College, Surrey, and must be returned by October 14.

The twentieth annual lecture conference arranged by the Industrial Welfare Society was held during last week-end at Reading University. It was attended by some 250 welfare supervisors, employment managers, personnel managers, and directors of firms, and these delegates were received by the director of the society, Mr. R. R. Hyde, who read a message from the King: "It is gratifying to me as your Patron to observe in the many factories which I visit that the principles for which the society has stood since its inception in 1918 are now being so widely accepted." Among the lectures given on September 6 was one by Mr. D. C. Norris, F.R.C.S., chief medical officer, Metropolitan Water-Board, on "War Production and the Health of the Worker," and another by Colonel J. R. Rees, medical director, Tavistock Clinic, on "War and the Worker: Some Psychological Aspects."

The *Anglo-Soviet Journal* will no doubt have a much larger circulation now than before the Nazi invasion of Russia. It is a well-illustrated quarterly, owned by the Society for Cultural Relations, edited by Dr. Geoffrey Ververs, and published by Lindsay Drummond, Ltd., 6, Buckingham Street, W.C.2, at 2s. a copy. The July issue (being No. 3 of Volume II) contains articles of topical interest, including one by Mr. Ruscoe Clarke on "Medical Theory in the Soviet Union." There are also some medical items in the miscellany headed Notes and News.

The Consultative Committee for the Director of Water Examination, Metropolitan Water Board, which is referred to in a leading article in this week's *Journal*, has the following composition under the chairmanship of Lord Horder: Dr. James Ferguson, Dr. Mervyn Gordon, F.R.S., Dr. Thomas Orr, Lieut.-Colonel G. S. Parkinson, Dr. Maitland Radford.

A Defence Regulation is to be issued immediately, the terms of which are: (1) This Order may be cited as the Paraffin Emulsion (Reduction of Liquid Paraffin) Order, 1941, and shall come into operation on the day of 1941; (2) on and after the date of operation of the Order no paraffin emulsion shall be manufactured containing more than 25% volume in volume of liquid paraffin. The reason for this Order is that while the use of liquid paraffin is essential in certain conditions it is possible to effect economy in its use. While proprietary brands of petroleum emulsions contain percentages of liquid paraffin as high as 65% by volume, the Therapeutic Requirements Committee and the National War Formulary Committee have both decided that an emulsion containing 25% of liquid paraffin is as effective as the pure oil. The National War Formulary, which is now in proof and will soon appear, includes a 25% emulsion. It will, of course, be permissible to dispose of existing stocks of emulsions containing more than 25%, but in due course the Order should effect a substantial saving in the quantity of paraffin used medicinally.

During the first two years of the war over £7,000,000 have been contributed to the Duke of Gloucester's Red Cross and St. John Fund. Lord Iliffe, chairman of the appeal committee, stated last week that the Red Cross and St. John War Organization was faced with ever-increasing commitments in all parts of the world, the outgoings of the Organization being nearly £11,000 a day. New calls were constantly being made upon the Red Cross from every front at home and abroad, and in recent weeks every service in the Middle East and Far East had been expanded and extended. Nevertheless revenue had so far progressively kept pace with expenditure.

Caldecote Hall, Nuneaton, was taken over by the Ministry of Health last year, but was later relinquished and has now resumed its normal functions.

No. 33

INFECTIOUS DISEASES AND VITAL
STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended August 16.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included), (b) London (administrative county), (c) Scotland, (d) Eire, (e) Northern Ireland.

Figures of Births and Deaths and of Deaths amongst Infants with infectious disease, don't (b) (d) The land.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

* Includes paratyphoid A and B for Eire and Northern Ireland.

† Includes primary form in figures for England and Wales, London (administrative county), and Northern Ireland.

‡ Includes one case of pneumonia not otherwise notifiable.

§ Owing to evacuation schemes and other movements of population, birth and death rates for Northern Ireland are no longer available.

EPIDEMIOLOGICAL NOTES

Infectious Diseases for the Week

A further decline in the notifications of measles was recorded during the week, 1914 cases being notified—a decrease of 362. A slight rise occurred in the incidence of scarlet fever, whooping-cough, and diphtheria. The notifications of these diseases exceeded those reported during the preceding week by 26, 52, and 22 respectively. In Scotland the incidence of diphtheria, measles, and whooping-cough declined, whilst scarlet fever showed an increase.

Dysentery

In striking contrast to the experience of the preceding week, when the number of cases was the lowest for several months, the notifications for the week under review showed a very large increase in England and Wales, and with a total of 196 reached a level that has only once been exceeded during the last three years. The largest of the local outbreaks were Essex (Colchester M.B. 17); Hertfordshire 60 (Berkhamstead U.D. 58); Yorkshire, West Riding 22 (Keighley M.B. 12); Pembrokehire (Pembroke R.D. 31). The increase in notifications in Scotland was due to an outbreak in the county of Inverness, 23. This county and the city of Dundee, 20, accounted for two-thirds of the total cases in the country.

Cerebrospinal Fever

One hundred and thirty-five cases of cerebrospinal fever were notified in England and Wales during the week reviewed, an increase of 14 compared with the preceding week. The largest number of cases were from Glamorganshire 10; Yorkshire, West Riding, 19; Lancaster 30 (Liverpool C.B. 9, Manchester C.B. 6). In Scotland the incidence declined, almost half the cases being reported from Glasgow, 12.

Typhoid and Paratyphoid

Twenty-six cases of typhoid and 166 cases of paratyphoid were reported in England and Wales. The largest increase was shown by Kent, and was due to 8 cases of paratyphoid occurring in Tonbridge R.D. The outbreak of paratyphoid in Cheshire and Lancaster persists, the number of cases reported for the past six weeks being: Cheshire 63, 44, 43, 25, 6, 15; Lancaster 146, 179, 133, 96, 76, 71, and of these 79, 78, 73, 70, 40, 40 were reported from Liverpool C.B.

Poliomyelitis

The number of cases reported in England and Wales showed a slight reduction, but isolated cases have appeared in several counties not previously affected. The outbreaks in Berkshire and Buckinghamshire are still the most important of the local epidemics. The returns for these counties are—Berkshire: New Windsor M.B. 2; Cookham R.D. 2; Buckinghamshire: Slough M.B. 4, Eton R.D. 2. A third death has been reported from the outbreak in the Slough area, a brother of a boy who died of the disease a week before. The only other area with more than one case was Southampton (Basingstoke M.B. 2). Multiple cases were reported from Scotland in the counties of Fife 2, Ayr 3, and the burgh of Glasgow 3.

F. I. Seymour and A. Koerner (*J. Amer. med. Ass.*, 1941, 116, 2747) record their observation on nearly 10,000 pregnancies obtained through artificial insemination, two-thirds of which were effected by use of the husband's semen alone. The proportion of boys to girls resulting was roughly 8 to 5 when the husband's semen was used and 7 to 5 when a donor's was used. Of the pregnancies 97% resulted in live and perfectly normal babies. The incidence of miscarriages and abortions was only one-fifth of that occurring normally in the population in areas where artificial insemination is not practised. The incidence of extra-uterine pregnancies was only one-sixth of that occurring normally. In all, 1,357 women had repeated pregnancies by artificial insemination. Successful pregnancies were reported with inseminations varying from 1 to 72.

A useful addition in bronchial cases is syr. toluatani, max to xss
In tonsillitis, potassium chlorate is not incompatible.

THE OPERABILITY OF CARCINOMA OF THE RECTUM

BY

J. C. GOLIGHER, M.B., Ch.B., F.R.C.S.

Formerly Resident Surgical Officer, St. Mark's Hospital, London

The Registrar-General's statistical review for England and Wales for the year 1936 reports 5,386 deaths from cancer of the rectum. This clearly indicates the magnitude of the problem presented by malignant disease in this situation—a problem, moreover, whose solution, in the present state of our knowledge, lies entirely with surgery. No assistance can as yet be sought from radiotherapy. It is particularly fortunate, therefore, that there are now available for this condition methods of surgical treatment, based on sound pathological knowledge, that are capable of yielding really excellent results. The writings of Miles (1939), Lockhart-Mummery (1934), and Gabriel (1937) leave no doubt on this point. If, however, the cure of rectal cancer on a large scale by surgery is to become a practical proposition it is essential that these methods should be widely applied: in other words, surgeons in general must endeavour to find operable a large percentage of the total number of cases of rectal carcinoma that they see. It seems to me that it is their failure to attain this objective that constitutes the most unsatisfactory feature of present-day treatment of this disease. Several surgeons have undoubtedly recorded high rates of operability in recent years: these for the most part, however, have represented the achievements of experts. It is strongly to be suspected that the unrecorded rate among surgeons who have no very special experience in this branch of surgery is still extremely low.

In considering the operability of rectal carcinoma it is essential to have a clear conception of the aims of radical surgery in this condition. The primary objective is—naturally to secure a complete eradication of the disease, as measured by freedom from recurrence over a period of five years; but even where this is not achieved the operation is not to be looked upon as having been completely valueless. On the contrary, excision has a high palliative value, which must not be disregarded in assessing the benefits of radical surgery. Practically all cases improve enormously in general health after an excision, and, even though recurrence should eventually take place, the patient may meanwhile have enjoyed two, three, or more years of comfortable and useful life. This contrasts very favourably with the fate of inoperable cases treated solely by colostomy. For though colostomy relieves the obstructive element it does little to alleviate the other distressing features of an inoperable growth—the severe sacral or sciatic pain, the profuse rectal discharge, the occasional severe haemorrhages, and the formation of fistulae externally or into other organs—which, singly or combined, may render death from this cause one of the most unpleasant imaginable. So that even for advanced growths, in which the chances of a radical cure are relatively slight, excision, where possible, is always justifiable, provided that the mortality can be kept within reasonable bounds. In the hands of surgeons who possess the skill to do this the standard of

operability can thus safely be raised so as to include a large proportion of these late cases.

It may be said at once that this is the attitude taken by the surgeons at St. Mark's Hospital, where approximately 120 new cases of carcinoma of the rectum are seen annually and where a high operability rate is observed. The present paper is a study of the operability of rectal cancer at that institution. It is based essentially on the recorded findings on all new cases of the condition dealt with over a period of ten years, from 1930 to 1939 inclusive—1,186 in all. Some additional material from the pathological department has also been included.

Definition of Operability

Cases classed as operable were those in which the surgeon considered the conditions favourable for a radical extirpation of the disease by operation. Not all of these patients did actually have a radical removal carried out. Some who were provisionally considered operable refused to have an excision performed because of their abhorrence of a colostomy; and others who were in the process of having such a removal and who were definitely known to be operable unfortunately succumbed after a preliminary colostomy operation or declined to proceed to the final stage. The prospect of ultimate cure was naturally less in some cases than in others, but no case was considered operable unless there appeared at the time of the operation to be some chance of complete cure. Patients on whom excision was performed but whose growths were known not to have been removed completely (as, for example, when a small secondary nodule was present in the liver) were not included. They were grouped as palliative excisions under the heading of "Inoperable" cases.

Table I shows the distribution of cases in operable and inoperable groups, and indicates the forms of treatment adopted.

TABLE I.—Analysis of Rectal Carcinoma Material at St. Mark's Hospital (1930-9 inclusive) (1,186 Cases)

Operable		Inoperable	
Expectant (refused operation)	23	Expectant	42
Radium	5	Curette and diathermy	4
Local excision	38	Radium	17
Colostomy or caecostomy	23	Laparotomy alone	10
alone*	14	Colostomy	357
Hartmann's operation	291	Palliative excision	11
Perineal excision	321		
Combined excision	715		
Total	715	Total	471
	(60.3%)		

* Died before the second stage of a radical excision or refused further treatment.

Inoperability was determined either by an unsatisfactory general condition of the patient which rendered him unfit for a radical operation, or by an advanced state of the growth which placed it beyond the reach of surgery.

Inoperability due to Patient's General Condition

A subnormal general condition of the patient was seldom accepted as a reason for refusing operation altogether, though it may have modified the form of treatment given. Actually only 92 (8%) of the cases were thus invalidated. This is important because the majority of patients suffering from carcinoma of the rectum are elderly, and often their general condition has been considerably undermined before they present themselves for treatment. In a number of cases no very special cause was present to account for the unsatisfactory state of the patient's general health, and such cases were merely described in the notes as being "in poor general condition." In others, however, some concomitant ailment (such as cardiac disease, chronic bronchitis, emphysema, pulmonary tuberculosis, unstable mental condition, diabetes mellitus, etc.) was noted, or the patient was very obese or elderly. It is to be emphasized, however, that as a rule these conditions constituted a contraindication to operation only when they were of an advanced nature, and not a few patients manifesting lesser degrees of the same conditions successfully withstood radical excision of their growths. Particularly to be stressed is the fact that no arbitrary age limit to operability was observed, as is clearly shown in Table II, which indicates the influence of age on the operability rate in 1,171 cases in which the data were adequate for that purpose.

TABLE II.—*Effect of Age on Operability*

Age Group	Cases in Each Group	Accepted as Operable	Operability Rate
20-29	25	15	60.0%
30-39	63	42	66.7%
40-49	145	106	73.1%
50-59	351	224	63.8%
60-69	443	260	58.2%
70-79	139	65	47.0%
80-89	5	3	—
All ages ..	1,171	715	61.1%

The optimal operability rate was in the age group 40-49. In older patients the rate declined, but even in the age-group 70-79 it was still practically 50%. The importance of a high operability rate in the upper age groups is amply demonstrated by the fact that more than half (587) of the patients were over 60 years of age. The lower operability rate in patients under 40 is not connected with the general condition at all; it is explained, as Dukes (1940) has shown, by the fact that in younger patients rectal carcinoma assumes a more malignant form, and by the time the patient comes to the surgeon extensive spread, rendering the growth inoperable, has more often taken place.

Inoperability due to State of Growth

Having excluded the patients whose general condition was completely unsatisfactory for any form of radical treatment, there were 1,094 cases in which the decision as regards operability rested solely on the state of the growth itself. Of these, 379 were found to be inoperable. The cause of inoperability was the presence of recognizable spread of the disease to points beyond the scope of an excision. This manifested itself in the following ways: (a) by local fixation of the growth (spread by direct continuity of tissue); (b) the presence of hepatic metastases (venous spread); or (c) extensive involvement of the lymph glands or peritoneum (lymphatic spread).

It is important to realize that it is only at laparotomy that an accurate assessment of the operability of a rectal carcinoma can be made. For, in the first place, clinical examination alone gives no reliable information as to venous or lymphatic spread, unless it is very extensive; and, secondly, fixity of the primary growth, as determined by rectal examination, is an untrustworthy sign on which

to base a diagnosis of inoperability. Growths which appear clinically to be fixed and inoperable are often found at laparotomy to possess enough mobility to permit of excision being performed. The explanation of this may be that during a rectal examination it is naturally difficult to impart movement with the finger to a growth that is sometimes so large as almost to fill the pelvis. At laparotomy it may be possible to grasp the growth with the whole hand and to test more exhaustively its range of movement in all directions. Whatever the explanation, however, there is no doubt of the fact, and it is one that thoroughly justifies the practice at St. Mark's Hospital of allowing all "borderline" cases to proceed to laparotomy.

Thus in the present series the decision as regards operability in no fewer than 893 cases (of which incidentally 621, or 69.7%, were operable) was deferred till the abdomen had been explored. In only 201 cases was a conclusion reached on clinical grounds alone; 107 of these were hopelessly inoperable cases (with fixed growths in nearly all, fistulae in 15, palpable enlargement of the liver in 19, ascites in 4, and fixed enlarged inguinal glands in 4), while 94 had apparently inoperable growths, in which confirmation of operability at laparotomy was precluded because the patient refused operation or because the treatment applied was of a restricted nature (e.g., local or perineal excision with "blind" colostomy) not involving exploration of the abdomen.

The part played by each of the three contraindications in determining inoperability will now be examined.

Contraindications to Operability: (a) Fixation of Growth

Fixation was noted in 261 of the inoperable cases. In 169 of them a laparotomy had been done and a definite opinion as to the presence of hepatic, peritoneal, or lymph-gland metastases could therefore be formed; in no fewer than 97 of these fixity of the growth was the sole cause of inoperability. An incentive is therefore provided for courageous handling of this complication.

The exact situation of the fixation was clearly defined in 174 cases. In 116 of these it was found anteriorly, in 23 posteriorly, and in 14 on the lateral walls; in 33 cases the rectum was fixed on more than one aspect. The enormous preponderance of anterior fixation is interesting, and is entirely in keeping with preconceived ideas on the subject; for it has long been recognized that the anterior aspect is the *face dangereuse* of the rectum. It is of course accounted for by the close application of viscera to the front of the bowel, so that a rectal carcinoma readily becomes adherent to them.

Influence of Site of Growth on Operability.—It follows from the above that the site of the growth in the rectal wall ought to have an important influence on its operability. Thus one originating in the anterior wall is early exposed to the risk of becoming adherent to the organs related to this surface, and its operability ought therefore, on the average, to be reduced. This is a danger which does not apply to posterior growths until such time as they have extended circumferentially round the rectum to form completely annular lesions, and their chance of becoming fixed to the sacrum is apparently slight. The operability of growths beginning in the posterior wall should thus be appropriately enhanced. The risk of a lateral growth becoming fixed to the parietes is probably not any greater than that of posterior growths, but the ease of extension to the vulnerable anterior wall would probably slightly diminish the operability of carcinomata arising in this situation. Confirmation of these conjectures is afforded in Table III, which shows the relation between the site of the growth and operability in 1,063 cases in which these points could be correlated.

TABLE III.—*Influence of Site of Growth on Operability*

Site of Growth		Growth in Each Site	Accepted as Operable	Operability Rate
Completely annular	Male	225	110	48.9%
	Female	112	60	53.6%
	Total	337	170	50.4%
Centred on anterior quadrant	Male	165	66	40.0%
	Female	71	42	59.2%
	Total	236	108	45.8%
Centred on one or other lateral quadrant	Male	165	130	78.8%
	Female	60	47	78.3%
	Total	225	177	78.7%
Centred on posterior quadrant	Male	190	157	82.6%
	Female	75	65	86.6%
	Total	265	222	83.8%

Influence of Sex.—Several surgeons have recorded their impression that the operability rate of carcinoma of the rectum is higher in women than in men, and have offered various explanations to account for this difference. A similar variation was observed in the present series. For of 354 women 228 (64.5%) were operable, but of 832 men only 487 (58.5%). It will be noted in Table III that the

Fig. 1.—Photograph of specimen with lymph-gland dissection from a case of carcinoma recti. A loop of adherent small intestine was removed along with the rectum by perineo-abdominal excision. Histologically the binding adhesion was composed entirely of inflammatory tissue. No lymphatic metastases were seen. The patient unfortunately died with hepatic deposits a year and eight months later.

difference in operability in the two sexes was especially marked in connexion with growths centred on the anterior wall, the higher operability rate for such in women undoubtedly being largely attributable to the greater feasibility, in female patients, of resecting portions of anteriorly related viscera when these are adherent.

The Nature of the Adhesions leading to Fixation of the Growth.—Though fixation is brought about by the direct spread of the primary growth, this does not necessarily mean that malignant extension to the adherent structures has occurred. The binding adhesions in many cases are purely inflammatory in character, presumably being formed as a reaction to the advance of the tumour through the rectal wall. Thus a histological examination of 34 operation specimens in which portions of adherent viscera were excised along with the rectum (vagina 20, uterus 3, prostate and seminal vesicles 8, small intestine 3) showed that actual malignant invasion had occurred in only 12 (vagina 5,

uterus 2, prostate and seminal vesicles 3, small intestine 2). The moral to be drawn from these observations is that the prognosis in cases submitted to these extended operations is often very much better than was imagined by the surgeon at the time of the excision. Where the general condition of the patient is good and the additional operative strain is likely to be well borne, therefore, the surgeon should not hesitate to employ these methods as a means of increasing the operability of growths adherent on the anterior aspect of the rectum. Fig. 1 illustrates a specimen removed by such an operation.

(b) Hepatic Metastases

It is naturally only in patients submitted to laparotomy that any accurate data are available as to the frequency of the occurrence of hepatic metastases. Of the 893 cases coming to laparotomy, liver secondaries were noted to be present in 103 (11.5%). It must be pointed out, however, that the surgeon's estimate as to the frequency is subject to fallacy. He can only determine the presence of secondaries on the surface of the organ (and not even all the surface at that!). Growths situated entirely centrally must of necessity elude detection. How grave a source of error this may be is illustrated by the following facts:

From 1930 to 1939 inclusive necropsy was performed at St. Mark's Hospital on 31 patients who had died a few days after perineo-abdominal or perineal excision of the rectum. In all cases a laparotomy had been carried out and the liver surface had been found to be smooth and free from secondary deposits; yet in no fewer than 5 cases secondary growths were discovered in the depths of the liver (see Fig. 2). These figures give an incidence of concealed liver secondaries of roughly 1 in 6 in cases coming to necropsy. If these findings obtain for the other cases which were considered at laparotomy to be free from hepatic metastases (790), then as many as 127 of these may have had such metastases hidden in their liver. The total number of cases with secondary involvement of the liver would therefore be raised from 103 (11.5%) to 230 (25.8%). The significance of these buried metastases is that many patients are inevitably subjected to so-called radical excisions when actually the disease has extended beyond the scope of any such operations and has involved the liver. This fact no doubt accounts in large measure for the frequency with which recurrence in the liver is recorded in the follow-up department in patients dying during the first two or three years after radical operation. In such cases the operation has unconsciously been merely palliative; but, quite apart from the impossibility of avoiding the mistake, the operation has probably justified its performance by the greater relief of symptoms than would have been obtained by colostomy alone.

Fig. 2.—Section of liver showing large central metastasis undetected at laparotomy. (From a patient who died one week after a perineo-abdominal excision for carcinoma of rectum.)

In 36 of the 103 cases in which liver secondaries were felt at laparotomy the growth was regarded as locally operable. In 11 of these, as an alternative to colostomy alone, a deliberate palliative excision was performed. In all the 11 cases the patient was in good general condition, and the liver secondaries palpated were very small and usually single, so that, though the liver involvement was almost certainly more extensive than appeared on the surface, that organ was not completely "riddled" with secondaries, and there was a reasonable period of survival to justify the additional risks of this most drastic form of palliation.

(c) Formation of Peritoneal Nodules and Extensive Involvement of Lymph Glands

These two occurrences represent spread of the growth by the lymphatic system. They were noted in 99 of the 894 cases undergoing laparotomy; in 88 of these cases, however, some other factor, such as fixation of the growth or hepatic metastases, was already present, rendering the condition inoperable. Lymphatic spread cannot therefore be said to play an important part in determining inoperability.

FIG. 3.

Peritoneal nodules or plaques were observed in 62 cases; they were usually confined to the floor or side walls of the pelvis or to the pelvic mesocolon. In 18 cases, however, extensive trans-coelomic spread had apparently taken place, and nodules were scattered throughout the peritoneum, being generally associated with ascites. The presence of any such plaques has in the past been held to contraindicate operation, but recently in a few cases in which the nodules have lain well within the limits of the operation field, and the growth has been otherwise operable, excision has been performed. Sufficient time has not yet elapsed to show whether the attempts at eradication of the disease in these cases have been justified either by success in the primary aim or by the degree of palliation afforded.

The extent of glandular involvement is often a difficult matter to assess even at laparotomy. Gabriel, Dukes, and Bussey (1935) have shown that 60% of the enlarged glands in association with rectal carcinoma are swollen purely as a result of inflammatory changes. The only cases in the present series, therefore, that were accepted as inoperable on account of glandular involvement were those (57 in number) in which hard fixed enlargement of glands, such as the para-aortic and internal iliac, provided unequivocal evidence of extension of the growth beyond the bounds of legitimate surgical enterprise.

In this connexion it is interesting to note the results of gland dissection of the operation specimens, which was made in 451 cases. In 231 cases lymph-gland metastases were present, and in 81 of these they extended right up to the ligature on the inferior mesenteric vessels, as shown in Fig. 3. That the involvement has extended to a still higher level in most of these latter cases is indicated by the frequent, almost universal, development of early recurrence. Fig. 3 illustrates an operation specimen from one of Mr. Gabriel's cases of carcinoma of the rectum. It shows widespread involvement of lymphatic glands (affected glands

shaded black). The patient surprisingly lived for four years after operation; and finally died of cerebral haemorrhage.

Choice of Treatment

It will be seen from Table I that a variety of methods have been adopted in the radical treatment of rectal cancer at St. Mark's Hospital. The principle underlying their application has been to employ the most radical operation that the individual patient may reasonably be expected to stand. The method of first choice, at any rate in recent years, has been the combined perineo-abdominal or abdomino-perineal excision. In a number of cases, however, the general condition has not permitted the performance of so severe an operation. It was to patients in this category, with growths of suitable situation and character that the alternative less drastic procedures were applied. Thus for patients with growths in the lower part of the rectum whose general health has not been good, perineal excision has had a wide sphere of usefulness. Similarly for growths in the upper third of the rectum it has occasionally been possible to carry out Hartmann's operation when the general condition would have made a combined excision especially hazardous. Finally, for many localized growths of apparent low malignancy in patients in poor condition it has sometimes been possible to use local excision or even radium treatment. Provided they are reserved for such early growths these local removals can be classed as radical operations; in fact, a number of five year cures are known to have followed their employment. The value of radium is admittedly less clear.

It may be affirmed, then, that the complementary use of these less radical methods in the manner indicated has played a valuable part in helping to achieve a high operability rate. The particular value of the perineal operation is demonstrated in Table IV, which shows that the operability of rectal cancer was greatest when the growth was situated in the lowest third of the rectum, this being explained by the fact that perineal excision was more readily available for "poor-risk" patients whose carcinomata were located in this segment than for those with growths at higher level.

TABLE IV.—Operability of Growths in Various Segments of the Rectum (1,096 Cases)

	Growths in Each Segment	Accepted as Operable	Type of Treatment Employed			Operability Rate
			Combined Excision	Perineal Excision	Other Methods	
Upper third ..	395	224	161	31	32	56.7%
Middle " ..	314	183	95	74	14	58.3%
Lower " ..	387	273	59	181	33	70.5%
Totals ..	1,096	680	315	286	79	62.0%

Operative Mortality

The operative mortality for the 321 combined excisions was 60 (18.7%). This figure, however, includes the earliest cases done by this method at St. Mark's Hospital, and is therefore unduly high. The present rate for this operation is just under 10%. The mortality for the 291 perineal excisions was 23 (7.9%). The number of cases submitted to other methods is too small to permit of any accurate statement of mortality. Altogether, of 687 operable cases receiving some form of surgical treatment (including cases whose sole treatment was colostomy or caecostomy) 10 were fatal, giving an overall mortality of 15.6%.

Summary

The operability of carcinoma of the rectum has been analysed in a series of 1,186 cases.

The operability rate for males was 58.5%, for females 64.5% and for both sexes 60.3%.

In 8% of the cases inoperability was due to the poor general condition of the patient, and in 32% to the advanced state of the growth.

With regard to age, operability was greatest between 40 and 49, and declined in patients older or younger than this.

Inoperability of the carcinoma itself was determined by the presence of one or more of the following conditions: local fixation of the growth, hepatic metastases, peritoneal carcinomatous plaques, or extensive involvement of the abdominal lymph glands. Laparotomy was usually necessary to decide on the existence of these contraindications.

Local fixation of the growth was noted in 23.9% of the generally operable cases, and in 18.9% of the cases that had laparotomy performed. The fixation was usually in front to the related pelvic or abdominal viscera. Growths involving the anterior wall of the rectum were much less frequently operable than those confined to the other quadrants of the bowel. The operability of anterior growths in women was higher than in men. The adhesions producing fixation were usually, but not invariably, inflammatory in character.

Hepatic metastases were palpable in 11.5% of the cases proceeding to laparotomy. The presence of concealed undetected metastases is postulated in another 14.3% of these cases.

Nodules of growth in the peritoneum or extensive involvement of the abdominal lymph glands were noted in 11.1% of cases submitted to laparotomy. These conditions, however, were seldom the sole cause of inoperability.

In endeavouring to secure a high operability rate the importance of having available several radical procedures of varying severity is stressed.

The operative mortality rate for all operable cases having some form of surgical treatment was 15.6%, for cases submitted to combined excision 18.7%, and for those submitted to perineal excision 7.9%.

I wish to express my thanks to the honorary staff of St. Mark's Hospital for permission to undertake this analysis of their cases, to Mr. H. J. R. Bussey for preparing the photographs of specimens and drawings, and to Mr. W. B. Gabriel and Dr. Cuthbert Dukes for their interest, criticism, and advice.

THE PARASITOLOGY OF SCABIES

BY

Professor P. A. BUXTON

London School of Hygiene and Tropical Medicine

It seems clear that scabies is increasing among civilians and soldiers. This has resulted in so many people inquiring for details of the life history of the itch mite that I venture to publish this account of what is at present known. I have not dealt with the methods of treating the patient or killing the mite, for it is believed that a summary of that side of the subject is in active preparation by other hands.

The correct name of the mite which causes scabies is *Sarcoptes scabiei* de Geer. There are a number of races which occur on different animals (see below), and that on man is known as var. *hominis*.

Appearance

The dorsal surface of the adult female itch mite is shown in Fig. 1. The figure is drawn from a specimen from the horse, but this variety is not distinguishable in structure from that occurring in human beings.

The general outline of the itch mite is oval: it is convex above and flat below, and of a dirty white colour, except the brownish bases of legs, etc. The body is divided into two regions by a constriction between the two anterior and two posterior pairs of legs. The greater part of the surface, dorsal and ventral, is covered with fine transverse folds, which are characteristic of *Sarcoptes* (and of certain related genera of itch mites which occur on domestic animals but not on man): the upper surface bears a number of specialized spines and conical scales.

FIG. 1.—Dorsal surface of adult female *S. scabiei* var. *equi*. (From Hirst, 1922.)

The anus is terminal. The legs are short; in the female the first and second legs terminate in suckers (ambulacra) carried on the ends of unjointed stalks; in the male there are similar suckers on the first, second, and fourth legs. The male also differs from the female in the large and elaborate genital organs lying on the ventral surface between the fourth pair of legs. The female is about 0.390 mm. long, the male 0.225 mm.

A full account of the external anatomy of the *Sarcoptes* of the horse (*S. scabiei* var. *equi*) is given by Buxton (1921a). There are grounds for thinking that the mites attacking horse and man are not to be distinguished from one another on anatomical grounds (Buxton, 1921b).

Biology: 1. Life Cycle

The life history of *S. scabiei* is extremely difficult to follow, for the mites are very small and delicate, and much of the cycle is passed beneath the surface of the skin of the host. The best account that we have is by Munro (1919), but there are many points on which knowledge is still most imperfect. According to Munro the adult female, removed from her burrow in the skin, is capable of burying herself completely in man's skin in a very brief period: she holds to the skin by the suckers of the front legs, and elevates her body into a nearly vertical position by using the long terminal bristles of the hind legs. This is generally done on some part of the human body of which the skin is thin. Once the mite is beneath the skin it rests if the man is in a cold place, and continues to excavate its burrow only if his skin is warm, as when he is in a warm room or in bed; it is when the mite is advancing through the epidermis that the itching is felt. It is assumed that the mites feed on the liquid that is available from the epidermal cells which they crush.

A part of the life history of the itch mite may be observed by opening burrows, or by dissecting them from the underlying tissues and mounting them whole (Fig. 2). It can then be seen that the first egg is laid within twenty-four hours of the female's becoming mature. The egg may

hatch in about sixty-five hours; but the period varies (probably with the temperature of the surface of the skin), and the stage may last as long as 100 hours, perhaps even longer. The egg produces an active hexapod larva (Fig. 3), which moults into an octopod nymph: at the next moult this produces either an adult male or an immature female, which has to moult once again to produce an adult female.

The duration of the successive stages is as follows (Munro, 1919): egg, $2\frac{1}{2}$ days or more; larva, $1\frac{1}{2}$ to 3 days; nymph, $1\frac{1}{2}$ to $2\frac{1}{2}$ days; immature female, 2 to 4 days. At

according to Munro (1919, p. 21) the isolated larva lives not more than thirty hours if kept moist. It is said that the infestation normally spreads to those with whom the patient sleeps, because the early stages of the mite normally wander about at night. But they are so small (the larva is only 0.15 mm. long) and inconspicuous, that they have seldom been seen.

2. Reproduction

The pairing of *S. scabiei* has not been observed. The accepted view (Vitzthum, 1931; Warburton, 1920; and earlier authors) is that the male pairs with the immature female, and that the adult female cannot pair. But it is now thought probable that it is the adult female which pairs, and that the orifice is on a minute papilla on the dorsal surface of the abdomen, not present in the immature female. If this is so the adult female has two genital orifices; for the eggs are laid through a transverse slit, the tocostome, on the ventral side, behind the bases of the legs of the second pairs (Buxton, 1921a).

The life of an individual female has never been followed through, but it seems probable that she lays rather more than two eggs daily, to a total of about forty to fifty.

3. Distribution: Seasonal and Geographical

The itch mite on or in man's skin must be exposed to extremely equable conditions of climate (even more so than *Pediculus*). It is not remarkable, therefore, that it appears to be cosmopolite, and that there is little evidence of seasonal change in abundance; where seasonal changes are observed they may be due rather to the effect of climate on the human beings (who may crowd together in cold weather) than on the *Sarcoptes*. The parasite may occur in people of all ages and races.

No information exists as to the upper temperature that is fatal for various periods of exposure. Disinfestation of blankets, etc., by heat is at present based on faith alone, and probably the temperatures used are needlessly high.

4. Hosts

It has been known for three-quarters of a century that mites very similar to the *S. scabiei* of man occur on many sorts of mammal, causing itching and mange. These mites have been recorded from the domestic horse, dog, pig, sheep, goat, camel, llama; also from a number of wild animals, among others the wolf, polecat, fox, lion, capybara, but generally from individuals kept in captivity. The earlier authors figured and described points of difference between *Sarcoptes* from different species of mammal, and their work was summarized by Warburton (1920): it is now held that the differences recorded are due to imperfect microscopes and technique, and that the anatomical characters are variable or non-existent. Hirst (1922) states that he has examined specimens from a large number of species of mammal, domestic and wild, "without being able to find a constant morphological character by which they could be satisfactorily distinguished from one another." I myself made a full study of the external anatomy of the *Sarcoptes* of the horse, and then examined much material collected from human beings: the conclusion reached was "that the *Sarcoptes* of the horse and the common species found on man cannot invariably be separated. Certain minute differences exist in scales and spines, but they are not constant, and the measurements overlap" (Buxton, 1921b). No species of *Sarcoptes* occurs on birds.

FIG. 2.—Diagram showing adult female itch mite and eggs in burrow in skin. Redrawn by H. S. Leeson, after Munro (1919).

shortest, therefore, the period from deposition of egg to emergence of adult female might be less than eight days.

The larva (Fig. 3) quits the burrow of its parent, in which it hatched from the egg, and makes its own burrow, which may be distinguished by minute vesicles beneath its floor. It seems probable that the nymph makes a separate burrow. Whether the males and immature females wander and make

FIG. 3.—Dorsal view of larva of *S. scabiei* (Buxton, 1921a). A, anal seta; an, anus; co, cone; D₁, first dorsal seta; H₁, terminal seta of third leg; L, lateral seta.

their own burrows or whether they continue in that made by the nymph is not known; but it appears to be well established that the adult female does not normally move, though she can start a fresh burrow if she is forcibly removed from the skin.

The larvae, and perhaps all stages, are sensitive to dryness, and one may suppose that there is a high mortality among those which are wandering over the host's skin or clothes. Even if humidity is high, it is thought that no stage of the mite is able to survive unfed for longer than a few days, though further information would be welcome;

As it seems that itch mites from man, the horse, and many other animals are not separable on anatomical points, though they differ physiologically, it is convenient to treat them all as belonging to a single species, *S. scabiei*. But as there is a high degree of specificity (see below) one would say that there are biological races associated with particular hosts. It is customary to speak of these varieties as *S. scabiei* var. *hominis* on man, var. *equi*, *canis*, *suis*, *ovis* on the horse, dog, pig, and sheep, and so on for other varieties.

5. Source of Human Sarcoptes

As we have no anatomical points by which *Sarcoptes* from different animals can be recognized one can only use the epidemiological method in studying the extent to which man may derive his infestation from other mammals. It is quite clear that one human being is normally infested from another: the itch generally spreads through a family, or a group of men living together, in the absence of infested animals. The condition is much more frequent in people who live crowded together and who have no opportunity of washing, changing clothes, etc. Moreover, experimental transmissions are on record: scabies has been transmitted to volunteers who used the underclothing or beds of infested people, or who wore gloves inside which *Sarcoptes* had been liberated (Munro, 1919; Macpherson, Horrocks, and Beveridge, 1923).

But though man generally derives his *Sarcoptes* from other human beings there are many records in which his infection was clearly traced from animals: such cases are often detected by veterinary surgeons. The disease seems to be not rare among those who keep small pet dogs, which can sleep on the bed or the lap, but it is rarer among those whose dogs are larger and less easily handled.

FIG. 4.—Dorsal surface of adult female of *Notoedres cati*. (From Hirst, 1922.)

It also seems probable that more human infections are derived from the horse than from other animals. The case described by Macdonald (1922) is instructive: a group of students spent periods of from two to five hours studying the dead body of an infested horse: all those who had direct contact with the horse suffered from itching and a papular eruption. In a similar way, men whose work brings them into contact with cattle or camels suffering from sarcoptic mange commonly acquire an infection: there are also records of its spreading to keepers in menageries from diseased llamas, kangaroos, chimpanzees, and other animals. The disease is therefore to some extent an occupational one among those whose pleasure or profession it is to breed dogs, nurse cats, milk cows, groom horses,

tame lions, box with kangaroos, or tend llamas. (Recent references: Sequeira, 1925; Whitfield and others, 1931. See also Warburton, 1920, for references to earlier authors.) A useful short account of the mites infesting domestic animals is given by Hirst (1922).

The mite *Notoedres* (*Notoedrus*) *cati*, parasitic on cats and rabbits (and less commonly dogs), occasionally produces infestation in cat-lovers. *Notoedres* is distinguished from *Sarcoptes* in its small size, the dorsal position of the anus, and other characters (Fig. 4).

The severity of scabies acquired by man from animals differs greatly with circumstances: in some instances the irritation is felt very soon after the mites have reached the skin—within an hour or so in some of the students described by Macdonald (1922). Mites derived from the camel appear to be particularly irritating; indeed, it is said that Robert's famous march from Kabul to Kandahar in 1880 almost broke down owing to sarcoptic mange in the camels and in those who looked after them. It is also thought that some of the cases of crusted scabies in man may have been derived from animals (see below). It seems that the biological races of *S. scabiei* which are proper to animals are not able to establish themselves on man, and that in many cases they make no complete burrows: moreover, the original human patient is not, apparently, a source of danger to other people. This specificity of different biological races of the mite is very marked, and it has proved difficult to infect one sort of animal from another by transferring mites and crusts. To what extent human beings suffering from *S. scabiei* var. *hominis* are a source of infection to domestic animals is not known.

Medical Importance: 1. Scabies

Scabies, or "the itch," is a specific disease caused by the presence of *S. scabiei* in man's skin. It seems that a period of eight to ten days commonly passes between the beginning of an infestation and the development of symptoms, and that period may be longer, perhaps much longer, in insensitive patients. The itching, which is the most noticeable symptom, is not caused by the presence of the mite in the skin, but by its activity in extending its burrow: it is therefore most troublesome when the patient is in bed or in a warm room.

The burrow (Fig. 2) is made in the deeper part of the horny layer of the epidermis, rarely reaching so deep as the granular layer. In sections it may be seen that the epidermis round the mouth of the burrow is oedematous. The layers of epidermis below the burrow are also frequently oedematous, with dilated lymphatics. A vesicle may be present beneath the burrow (perhaps only when the burrow is that of a larval mite—see above). In the papillary layer the blood capillaries are dilated and surrounded by inflammatory exudate. The burrow is tortuous and may reach a length of 5 to 15 mm.

Scabies is best diagnosed by finding the burrow or the mite. In a European the burrow may appear grey because its rough upper-surface catches dirt and because of the faeces of the mite within it: one may make it more evident by brushing ink over the skin. It is generally agreed that the burrow is difficult to see in a brown skin. The mites will generally be found in the burrow, more rarely on the surface of the skin. Backhouse (1929), working with dark patients in Melanesia, reports finding the mite in 35% of 424 cases. It is sometimes very important to detect scabies—for instance, in order to prevent its spread through labourers in the Tropics or troops under active service conditions: failure to diagnose the condition is common. There is also a tendency in the damp Tropics to take scrapings from the skin and grow from them various fungi, which

fascinate the dermatologist and may prevent his discovering the common humdrum mite.

The infestation may be on almost any part of the body, and mites confined under watch-glasses will burrow wherever they may be. But the parts most commonly affected are those where the skin is soft or folded, as at joints.

On the clinical side one may distinguish simple scabies, in which the irritation is due to the burrows, and complicated scabies, in which the symptoms are aggravated by septic complications. Common complications are impetigo and the dermatitis which follows the unwise use of sulphur ointment. The proportion of complicated cases depends on conditions of life and the care given to diagnosis and treatment.

2. Crusted Scabies

Clinically this is a well-defined condition, thick crusts and callosities being found on various parts of the body, especially the limbs. The crusts, which are stratified, may project 2 to 3 mm. above the surface of the skin: large areas of skin may be involved and the finger-nails be included. Enormous numbers of *Sarcoptes* of all stages live in the crusts, but they are quite capable of burrowing in the normal way (Backhouse, 1929; and Fig. 5).

FIG. 5.—Section of skin from case of crusted scabies. Note great thickening of stratum corneum, and numerous burrows and spaces in it containing mites and eggs. Malpighian layer shows proliferation and mites lying deep in it in capsules of semi-cornified epithelium. Drawn by H. S. Leeson from a photograph by Backhouse (1929).

Generally the condition requires at least a year for its development. The accumulation of crusts, consisting of dead epithelium and dried exudate full of itch mites, renders it very much like sarcoptic mange, such as one sees in the horse. The disease is generally rare; most authors remark on the fact that the cases are isolated, one only being seen in many years.

The condition was originally described among lepers in Norway, and it is sometimes referred to as "Norwegian crusted scabies." This name is unsuitable, for the disease has been recorded from most European countries, and Turkey; also from several tropical countries, such as Brazil, French Guinea, Melanesia, and Java.

With respect to the epidemiology diverse views are held. Many authors regard the disease as normal scabies which has been neglected, perhaps because it occurs in an insensitive or very careless patient: the fact that it sometimes occurs in lepers, whose skin is so often anaesthetic, supports this view. Moreover, Beatty (1915) described a case seen in Dublin in which the infection was attributed by the

patient to his having slept a year before in the same bed as a person suffering from ordinary scabies. This view is supported by Pozzo (1920) and Mandoul (1925). The view that crusted scabies is nothing more than ordinary scabies much neglected is also held by Backhouse (1929). Some of his cases were mild and localized common itch; others were generalized; others, again, carried masses of crusted exudate full of *Sarcoptes*: the conditions graded into one another. Material collected by Beatty in Dublin has been carefully compared with a large number of mites derived from human cases of common scabies. It was found that the mites were separable only on one character—the length of the spines on the posterior part of the body; but the differences were small, and as the spines are curved they are not easy to measure (Buxton, 1921b). It would be difficult to say whether the small differences might be attributed to the conditions under which the mites live beneath the scales of crusted scabies.

The alternative view, that the mites in crusted scabies are derived from animals and are completely different from those in the ordinary disease, was held by several of the earlier authors, including Mégnin, who attributed certain cases to infection derived from wolves. More recently Brug and Haga (1930) have reported on mites derived from crusted scabies in a Chinese leper seen in Java. It is clear that their mites differed in several important characters from those which cause the ordinary disease, and it is perhaps significant that the same authors examined mites from a tame monkey, finding them identical with those from the human case of crusted scabies. In a case observed at Rio de Janeiro the mites differed from those of ordinary human scabies: it was thought that they must have been derived from an unknown domestic animal (da Costa Lima, 1927).

It seems, then, that crusted scabies may be produced in two ways. Sometimes, perhaps most often, it is ordinary itch occurring in an insensitive or neglected individual. Other cases are due to infection with *Sarcoptes* derived from animals. Both views are supported by the evidence. The third possible view, that the disease is peculiar to man but essentially different from common scabies, is not tenable because of its rarity and its tendency to appear as single cases.

Figs. 1 and 4 are reproduced from Hirst's *Mites Injurious to Domestic Animals*, by permission of the Director of the British Museum (Natural History). Figs. 2 and 5 are redrawn by my colleague Mr. H. S. Leeson from the figures of Munro (1919) and Backhouse (1929). Fig. 3 is reproduced by permission of the editor of *Parasitology* (Cambridge University Press).

Summary

The paper deals with the external anatomy and life history of *S. scabiei* var. *hominis*, the causative organism of human scabies, and its relation to man. Destruction of the mite and treatment of the host are not discussed.

The mite is a specific parasite of man, and can live for only a short time away from him. It can go through its cycle from egg to adult in a minimum of eight days. It seems probable that two types of burrow are made—one by the larva, with a vesicle in the floor, and the other (the larger and more familiar type) by the nymphs: it is in this second type that adults, eggs, etc., are found (Fig. 2).

Normally the itch is derived from another human being. But man is occasionally infested by the *Sarcoptes* of horse, camel, etc., which appears to set up a transient form of itch.

Crusted scabies is sometimes due to prolonged neglect of ordinary scabies. There are, however, some cases which are probably due to infestation by *Sarcoptes* from some host other than man.

TREATMENT OF SCABIES

USE OF SULPHUR LATHER TABLETS

BY

DOROTHY L. CARTER, M.B., B.S.

Recently Assistant School Medical Officer in Middlesbrough

The increase in the incidence of scabies, started well before the war, has now become a wartime problem. Among the school population, where information of a non-notifiable disease is easiest to find, scabies increased 90% in Heston and Isleworth, 100% in the North Riding of Yorkshire, and 50% in Coventry, in 1938. These figures are pre-war, but it is legitimate to assume that conditions which caused such an increase then will have caused a still greater increase in wartime, for the war has exaggerated many of those conditions. One of the chief reasons before the war was, as stated by Sir Frederick Menzies, the fact that "children who have been treated return to homes where other members of the family are untreated and reinfection is frequent." This fact is surely the basis for the alarming increase. Scabies is a curable disease; the remedies are varied, but the majority are effective sarcoptocides. Given an isolated case of scabies few practitioners will fail to cure it in a week. The cure of the individual case is relatively easy, and yet the disease remains one of the most difficult to control, and is at present assuming the proportions of an epidemic.

Anyone dealing with scabies on a large scale will acknowledge that the more cases we cure the more we find to cure. It seems feasible, therefore, to deduce that the disease is increasing because: (1) supervision of contacts is not given the same importance as the treatment of active cases; (2) 50% of the cases never seek treatment and thus constitute a reservoir from which fresh cases are always arising. The majority of individuals in this reservoir of untreated cases are those who escape medical supervision in schools, factories, and industrial concerns—children below school age who elude the rather infrequent visits of the health visitor, mothers and female relations who do not work outside their homes, and children above school age who do not come under medical supervision at work. Medical supervision would have much reduced the incidence of the disease had it not been for these untreated cases. The importance of control of the contact is increased by the fact that the war has caused a dispersal of the family unit. A family which before the war kept its scabies more or less to its own house now carries it to the Army, the air-raid shelter, and the reception area. The soldier home on leave takes his wife's scabies back to the barracks, the school child returns to the reception area with the baby's scabies, and the "bombed-out" family crowd in with neighbours or in a communal shelter, and the

acarus, if present in clothes or bedding, spreads rapidly. Shelter life and, indeed, all conditions of overcrowding, too often associated with personal uncleanness, fewer baths, fewer washdays, all provide excellent facilities for the increased spread of scabies.

Infection is by contact. This must be close contact with an infected person's lesion or with his infested clothing, and must be long enough to allow the acarus to pass from one person to another and to establish itself by burrowing in the skin. Thus infection will result from sleeping in the same bed as an infected person, using infested blankets—for example, in the Army, the shelter, or the crowded house—or wearing an infested person's clothing; it is possible that in some cases infection passes from clothing to clothing. Infested clothing remains infective for at least eleven days (Gray, 1940).

Importance of Effective Treatment

Scabies, which is frequently venereal (Roxburgh, 1939), is often regarded as a trivial disease, and is put with "nits" into the class of normal affections of some of the poorer people. This is unwise, for the importance of scabies lies in the fact that while it is never a life destroyer it causes much loss of sleep—an important fact nowadays. The cardinal symptom is intense irritation at night-time. The scabetic child, unless inured by months of reinfection, is pale, listless, heavy-eyed, and dull, not, of course, only because of his scabies but because of loss of sleep and his perpetually irritating skin condition. Similarly, we can ill afford to let the war worker spend his days and nights scratching, with a resultant increase in nervous tension, lack of concentration, impairment of efficiency, and eventually loss of working time.

The ideal treatment must be: (1) short and effective to reduce the period of infectivity; (2) palatable to the patient, who often has to be cajoled into continuing with it; and (3) must include all contacts and clothing. The futility of treating the school children and neglecting the contacts is expressed by Macdonald (1941): "The usual means of dealing with scabies by treating the children with clinic baths and instructing the mothers is not only inadequate but in the vast majority of cases is a futile expression of hope." On the other hand, the effectiveness of dealing with case and contacts together has been proved in Canada (Currey, 1939). On the day of diagnosis of a case of scabies the health visitor treated the case and all the contacts of school age in their own homes with benzyl benzoate lotion. All were excluded and followed up in twenty-four hours. Advice was given to the parent and lotion left for the remaining members of the family. In this way the incidence of scabies was, during the first six months of 1939, twelve families out of a school population of 5,569. This is an interesting record, for although only school-age contacts were treated, yet incidence of scabies among the schools fell to a very low figure.

A New Method of Treatment

I have recently used a new method of treatment, on children of all ages in a school treatment centre. In a small series of cases this was agreeably successful, and I think it is justifiable to add yet another to the list of sarcoptocides, for this one has certain advantages over others I have used, especially in children. This treatment was first described in America (Nolan, 1937). The active principle is sulphur—the old favourite. This is incorporated in a bland soap—amount of sulphur being 18%—which is applied to the body in the form of a lather. As the lather dries a thin film of sulphur is deposited all over the body. Nolan had noted that on looking at a bubble of the lather

the finely divided granules of sulphur could be seen, and as the bubble burst these granules were deposited on the skin. It was estimated that 4 grammes of the soap were needed to cover the body with a lather, whereas 85 grammes of sulphur ointment were commonly used. Nolan estimated the equivalent of sulphur as 0.72 gramme against 12.8 grammes. This meant not only a saving of material but less likelihood of sulphur dermatitis, as the amount of sulphur used was so much less. Working on Nolan's principles, I used, instead of a soap, a tablet in which the amount of sulphur suggested as adequate—that is, 0.72 gramme—was incorporated with a lathering agent. This was thought advisable for several reasons. Scabies baths are often given by untrained persons, and with a cake of soap it is as possible as with an ointment to use too much and cause a dermatitis. I used these tablets on twenty-nine unselected cases of scabies at a school clinic. In the majority of these the baths were given by V.A.D.s on my instructions.

FIRST SERIES OF NINE CASES

Procedure.—(1) Each child was given a hot bath; five were scrubbed with a nail-brush or harsh flannel and four were bathed clean without friction. (2) Child removed from bath and lathered all over with the tablet, a foam being produced by rubbing the tablet between the nurse's wet hands. (3) Lather allowed to dry; this took about five minutes in a warm bathroom. (4) Clean vest put on. (5) Procedure repeated on two successive

the child from scratching the tags of dead skin. It is notoriously difficult to make children attend regularly for baths, and in this series the longest time taken to give the three applications was five days.

Result.—Out of twenty cases two defaulted. Eighteen were given three applications; all cured seven days after the last bath. One case of dermatitis. This child was seen to have a patch of urticaria on his abdomen at the follow-up inspection. No sign of dermatitis was seen during treatment, and in my opinion this was not a sulphur dermatitis; it cleared with calamine lotion in three days.

Comment.—The lathering method of applying sulphur has been used fairly extensively in America. I have found it in a very small series of cases to be a nearer approach to the ideal for children than either ung. sulph. or benzyl benzoate lotion. It is effective, as sulphur always has been, and the chance of dermatitis seems to be very small; moreover, by giving the patient three tablets treatment can be carried out at home without the fear of an excessive application by the zealous-minded. It dries quicker than a lotion and has none of the "messy" qualities of an ointment. Scrubbing before the application is probably necessary, or at least advisable; I found scrubbing was not necessary for children, in whom a hot bath and rub down with a flannel is generally sufficient to open the burrows. None of the children complained of pain after the lathering, even those with raw or septic areas.

Table showing Details of the First Series of Nine Cases

Case	Age	Sex	Degree	Complications of Disease	Duration of Treatment	Scrubbing	Previous Attacks (Recorded)	Complications of Treatment	Remarks
1	10	M	Moderate; abdomen, hands, and feet	None	1.2.3.	Yes	Baths at clinic with ung. sulph. since Nov. 1939	None	Attendance of this boy was very irregular before trial with sulphur lather. He was constantly getting reinfections
2	8	F	Severe; abdomen, back, and wrists	Septic burrows on wrists	1.2.3.	Yes	Several recurrences	None	Cured in 3 days with 3 baths
3	13	M	Moderate; abdomen round umbilicus, fingers	None	1.-2.3.	Yes	None	None	Brother of Case 4. Cured in 4 days with 3 baths
4	11	M	Severe; trunk, thighs, and feet	None	1.-2.3.4.	Yes	None	None	Brother of Case 3. Cured in 5 days with 4 baths
5	10	M	Slight; hands only	None	1.2.	Yes	None	None	Cured with 2 applications
6	8	M	Very severe; numerous burrows all over back, abdomen, thighs, and forearms	Septic burrows	1.-2.3.-4.	No	One recorded attack in Jan., 1939	None	Brother of Case 7. Cured in 7 days with 4 applications
7	5	M	Same as Case 6	Same as Case 6	1.-2.3.-4.	No	None	None	Brother of Case 6. Although this child was not scrubbed he opened most of the burrows by scratching
8	11	F	Severe; abdomen, buttocks, and forearms	Some areas of sulphur dermatitis on abdomen	1.2.3.	No	None	None	Scabies for 4 weeks before seen at clinic. Treated at home with paste of sulphur and lard after hot baths (no scrubbing). Thus, no doubt, account for sulphur dermatitis when first seen
9	12	M	Mild; abdomen and between fingers	None	1.2.	No	April, 1940	None	Cured after 2 applications. Reviewed 7 days later—still clear

Cases grouped into mild, moderate, and severe.

Duration of Treatment.—Each application of sulphur foam is numbered 1.2.3., indicating three applications on three successive days. If a day is missed it is denoted thus: 1.-2.3., indicating that the child did not attend on the second day so had its second application on the third day.

days. (6) Verbal instruction given to the parent about boiling the clothes and sheets.

Result.—Cases seen seven days after last bath: all cured. Average number of applications, three; average duration of treatment, four days. No cases of dermatitis.

SECOND SERIES OF TWENTY CASES

All children were given the treatment as outlined for the first series, but no one received more than three applications, as I thought this should be sufficient. Ten were scrubbed and ten were washed in hot water before lathering, four receiving their treatment at home. The majority were given ung. zinc. B.P. or calamine lotion to apply for the week following the last bath. This I found advantageous, as the skin often showed excoriations and scratch marks, although the scabies was cured. The ointment rubbed well into the skin promoted healing and prevented

Comparison with Other Treatments

Sulphur Ointment: Ung. Sulph. B.P.—This is the traditional treatment for scabies, and I have used it on children for some time. Its effectiveness is indisputable, but it is not my treatment of choice, for three reasons: (1) The use of any ointment spread thickly over the body means that underclothing and bedding become coated by the grease. This, combined with its rather pungent smell, makes the treatment objectionable to many people; their satisfactory co-operation is difficult to obtain. (2) There is the likelihood of sulphur dermatitis if the ointment is used too thickly or too frequently. Sulphur dermatitis associated with scabies is not only very difficult to cure but also often difficult to diagnose. (3) All the burrows

scratching had ceased and that the areas of skin most involved looked dull and brown in contrast to the bright pinkish points normally distributed freely in the scratched areas. Each child was re-examined after four days and again a week later. Subsequently the number of examinations was curtailed by omitting the second. The crusted or pustular areas of secondary infection were treated with a 1% ammoniated mercury ointment, after completion of the proscabin treatment. Under the procedure now in operation a child can be pronounced free from infection on the fifth day after diagnosis—that is, three days elapse between the signing of the exclusion form (school) and the issue of a return-to-school certificate, on two of which days proscabin is being applied. If a second course is deemed necessary the child can be passed fit for school on the ninth day. These results compare favourably with Canadian experience (Ministry of Health Memorandum, 1940). All cases are, of course, being observed one week later as a precautionary measure (Table I).

TABLE I.—Benzyl Benzoate Cases

Group	Number of Benzyl Benzoate Courses	Distribution of the Infection			Totals	Having Secondary Infection (%)	Later Sulphur Inunction (%)	Previous Infection with Scabies (%)	Number of Defaulters
		Trunk and Limbs	Limbs Only	Slight Cases					
I	1	40 (57.1%)	10 (83.3%)	17 (94.4%)	67 (%)	4 (%)	13 (%)	9 (%)	2 (%)
II	2	26 (37.2%)	2 (16.7%)	1 (5.6%)	29 (%)	6 (%)	4 (%)	13 (%)	0 (%)
III	3	4 (5.7%)	0	0	4 (%)	0	0	0	1 (%)
Totals		70(%)	12(%)	18(%)	100	10(%)	17(%)	22(%)	3(%)

It will be noted that the group requiring one course comprised 67% of the total cases treated; 29% required two courses before being pronounced free from infection; while four cases (4%) were given three courses. The proportion of cases given two courses is higher than it might have been because a misunderstanding on the part of the nurse attendant led to the omission of the preliminary bathing in about twelve cases. Most of these were early and mild, and it was the failure of cure to take place immediately—an expectation based on earlier experience—which led to the omission being discovered.

Twenty-five of the Group II cases were classed as not cured after one course of proscabin, and four were regarded as possible reinfections, recurrence taking place after an interval of one week or more. In this connexion I would like to emphasize the importance of having the everyday outer garments disinfested as well as underwear. Recurring infection of the thighs and groin from trousers (usually worn without underpants in most of our cases) and of the wrists from dirty and contaminated sleeves is of particular importance among poor children who have one suit of clothes only.

It will be noted further that seventeen cases of the one hundred treated were given sulphur inunction subsequent to benzyl benzoate. The ointment was applied solely to the cases in which itch continued, and only to the parts which are known to be particularly resistant to treatment and to be likely to harbour residual infection—namely, the thickened papule-ridden folds at the wrists, elbows, ankles, and groin. Thirteen of Group I cases (19.4%) and four of Group II cases (13.8%) were given such additional treatment. It is probable that a second course of benzyl benzoate might have cleared a number of those in Group I without the assistance of sulphur ointment, and we are proceeding along these lines now. The incubation period of the ova being three to three and a half days (Gray, 1933), it is not unlikely that, if any ova remained viable within the

thickened skin, larvae might appear after the completion of the single course of benzyl benzoate. Sulphur ointment was therefore prescribed as a prophylactic and precautionary measure.

I have already mentioned that quite a number of the cases which came under observation were from previous scabies-free households; these amounted to 88% of the total. The remaining 12% had had anti-scabies treatment within the preceding two years, and some were the victims of repeated attacks. In the group receiving only one course of benzyl benzoate there were nine cases (13.43%), while in the smaller Group II there were thirteen cases, or 44.82% of the group. These habitual sufferers formed almost half of the group which required two courses; they are the most difficult to cure and the most prone to reinfection. Default was practically negligible, only three cases being recorded. Two of these were due to intercurrent infection (mumps); the third patient was unwilling to attend after initial treatment.

Sulphur Inunction Cases

For comparison with the above and with particular reference to the length of time required to effect cure I include a brief summary of the last 100 cases treated by the sulphur inunction (ung. sulph. 5%) method. These cases are arranged according to the length of time between exclusion from school on account of scabies and the issue of a return-to-school certificate (Table II).

TABLE II.—Showing Length of Time to Effect Cure with Sulphur Inunction

Distribution of Infection	Cured within One Week	Cured within One to Two Weeks	Cured within Two to Three Weeks	Cured within Three to Four Weeks	Requiring Four or More Weeks	Prolonged Absence (illness, etc.)	Recurrences with Distribution of Infection			Totals
							1st Infection	2nd Infection	3rd Infection	
Trunk and Limbs	7	16	17	12	15	6	11	10	1	64 (%)
Limbs only	6	5	4	0	0	0	1	2	1	14 (%)
Totals	13(%)	21(%)	21(%)	12(%)	15(%)	6(%)	12(%)			100

It will be seen that only 13% of this series were reported fit to attend school after one week's treatment, as compared with 67% of the benzyl benzoate group, and as many as 15% were still uncured four weeks after diagnosis. These results cannot be used as a valid criticism of the efficacy of sulphur inunction, but they illustrate the difficulties of this method for out-patients who are receiving voluntary treatment and of whom many are apathetic and non-co-operative. As an indication of the position ten children in the "two to three weeks" group received no treatment on eight days or more of that period, so that in addition to week-ends without treatment each of these was absent on several days at least, usually irregularly and quite often at the most active stage of the treatment. Default during treatment reached even higher proportions in the "three to four weeks" and in the "four weeks and over" group. Irregular attendance at the clinic, principally due to the dislike many of the children have for this rather greasy and odoriferous treatment, and the prolongation of the course which default entails, are responsible for the deplorable figures that we have to record. That our experience is not unique is suggested by the recent Rotherham view that "the usual method of dealing with scabies . . . is not only inadequate but is, in the majority of cases, a false expression of hope" (MacDonald, 1941); while Peter, referring to his cases in Yorkshire, complains also of the difficulty of obtaining thorough treatment in the early stage of infection (Medical Officer, 1940). With regard to the

twelve recurrences recorded, all took place after an interval of one month or more from cessation of treatment for the previous attack: one case had had two previous attacks.

Conclusion

In my opinion the introduction of the benzyl benzoate treatment is an important advance in the treatment of scabies, and it is particularly valuable where large numbers are infected. The ease and speed with which the applications can be carried out, the absence of unpleasant effects apart from a temporary prickly sensation during the painting process, the rapidity of cure, and the almost immediate relief from itching combine to make it a satisfactory remedy from both the clinical and the public health aspects.

THE TRANSMISSION OF SCABIES

BY

KENNETH MELLANBY, Ph.D.

Sorby Research Fellow of the Royal Society

There has been a good deal of controversy concerning the way in which scabies is transmitted. Much importance has been attached to blankets, and an extreme view is expressed by Lydon (1941), who says that, at least in the Army, "it cannot be stressed too strongly that blankets are the chief means of spread of scabies infection, and unless strict control is instituted cases will continue to appear in their present numbers." The view that blankets are a common method of transmission is widely held in the Army, and the first reply made to the medical officer by the scabies patient when questioned concerning infection usually suggests that blankets were concerned—even from men—recently on leave to homes ridden with the disease. On the other hand, certain workers, particularly those in France, have considered that scabies is primarily spread by personal contact, and have suggested that it may be considered as a venereal disease. Working under controlled conditions, Munro (1919) has shown that scabies may be transmitted by fomites, but his results do not indicate how often such transmission is likely. The experiments described here are part of an investigation to find out exactly how the disease is normally transmitted.

These experiments were made using volunteers who lived under controlled institutional conditions and who were subjected to different types of contact with scabies infection. The volunteers were all pacifists who had offered to co-operate in this work and who, during the experiments, received board and lodging and a weekly payment similar to that which they would have received had they been called up for military service. They agreed to submit themselves to infection and to allow the course of the disease to be followed on their persons. Throughout the experiments the volunteers co-operated loyally, and I have had no reason to suspect that all instructions were not always conscientiously carried out. The expenses of the investigation were paid by the Ministry of Health.

Experimental Work

Fomites.—The volunteers were put in contact with blankets and underclothing previously used by scabies patients. Care was taken to use fomites only from patients about whom there was no doubt of the diagnosis of scabies. Where bedding was used it had normally been in contact with the patient for several weeks, and for the last twenty-four hours before transfer the two inside blankets in contact with the patient were the same as those subsequently in contact with the volunteer. In most of the experiments using blankets alone the volunteer was naked so as to ensure contact. The volunteer never bathed for a period of at least a fortnight after the beginning of an experiment; and later, when it was felt that it might be a disadvantage for him to start with too clean a skin, bathing was prevented for a further week before the experiment started. Bedding and underclothing were used by the volunteers for a period of seven days, the bedding being slept in at night only, whereas the underclothing was worn continuously, day and night. In the earlier experiments the blankets and underclothing were kept for periods of several days under conditions of known temperature and humidity. I hoped thereby to discover how climatic conditions influenced the infectivity of the materials. When a dozen or more experiments had been made without infecting the volunteers it was thought best to work under conditions which would appear to offer the maximum chance of infection. The results obtained in all these experiments may be summarized as follows:

- (a) Volunteer used blankets one to seven days after they had been used by scabies patient: 6 experiments, all negative (i.e., no volunteers infected).
- (b) Volunteer used underclothing two to seven days after it had been used by scabies patient: 6 experiments, all negative.
- (c) Volunteer used bed immediately it was vacated by scabies patient: 19 experiments, all negative.
- (d) Volunteer used underclothing immediately after it was removed from scabies patient: 32 experiments—30 negative, 2 positive (i.e., 2 volunteers became infected).

The men were stripped and inspected daily for a period of about a month (sometimes longer) after each experiment. The inspection took several minutes, and any suspicious lesions or areas in which irritation was felt were scrutinized with a high-power lens or a binocular microscope. Although work at present in progress shows that in some cases at least seven weeks may pass before clinical signs of scabies develop in an infected volunteer, some signs of infection are always visible to careful inspection at an earlier date, and, considering the care with which the daily inspections were carried out, I do not think it would be possible for any inspections to have been missed. Furthermore, the same men were used throughout the whole series of experiments, so that a slowly developing case would have eventually been detected.

Personal Contact.—When two infected volunteers were at last obtained it became possible to test the effects of personal contact. On four occasions uninfected volunteers slept together in the same beds as these men suffering from scabies. The scabies patients both had a general infection of the body (this was two to three months after their contact with infected underclothing), and the disease would probably have been detected at a routine inspection such as is commonly held in the Services, but the degree of infection was very much less than that usually seen in patients coming for treatment. The men wore pyjamas during these experiments. In three instances the volunteer and the infected man slept together for seven nights, and mites were found on all three volunteers after periods of

eight, nine, and twelve days from the start of the experiment. In a fourth case the volunteer slept for two nights under the conditions described above and did not develop the disease.

Conclusions

In 63 experiments using underclothing and blankets scabies was transmitted twice only, although everything was done to favour transmission. In none of the experiments (25 in all) using blankets alone was infection transmitted, and I think we are justified in assuming that under normal conditions blankets can seldom be responsible for the transmission of the disease. On the other hand, a small number of the experiments have shown that transmission by comparatively slight personal contact may be readily accomplished.

I believe that scabies is normally transmitted by personal contact either of a slight or of a venereal nature. There is no doubt that small children are often the first members of a family to be infected; the way in which children play with their arms around each other's necks suggests an easy means of transmission. Children then probably infect their mothers, who pass on the scabies to the father. An investigation of scabies in the Army shows that while a large number of cases may be traced to infection on leave, some other cases are due to illicit intercourse. It is difficult for an Army medical officer to obtain this information from a soldier, but it is possible to find out a good deal from resident patients by means of suitably chosen orderlies, to whom the patients will discourse more fully concerning their experiences. There is very little evidence to suggest that in this country scabies is being commonly spread from man to man in the Army.

One reason for the importance that is attached to fomites in scabies transmission is that lice are well known to be spread by this means, and as both scabies and pediculosis are parasitic diseases it might be expected that transmission would occur in a similar manner. As, however, the itch mite lives beneath the skin of the host during the major part of its life, and the body louse lives on his clothes, only going on to the body to feed, it is not surprising that considerable difference should exist.

The evidence given here is not sufficient to enable us to say that disinfection of clothing and blankets is unnecessary in cases of scabies, though this conclusion seems quite probable. I hope that it may be possible for other workers, particularly public health authorities, to obtain more extensive evidence. I may add that in many cases where reinfection has been attributed to fomites one of three possibilities has not always been excluded:

1. Contact with another case of scabies (a person who is once infected is likely to continue to have the same contacts, with continual risk of infection).
2. Incomplete cure, which may take several weeks to manifest itself.
3. Certain lesions remain visible and irritant for weeks after cure, and unless living parasites are found it is dangerous to consider that a reinfection or relapse has actually occurred.

G. D. Kettelkamp and W. W. Stanbro (*Amer. Rev. Tuberc.*, 1941, 44, 104) state that two identical male twins were admitted to hospital with a history of common initial symptoms of pain in the left chest, cough, and expectoration. Both were treated by artificial pneumothorax. The clinical course was similar, both patients developing laryngeal tuberculosis. Both died, and the necropsy showed in each tuberculosis of the lungs, larynx, intestines, liver, and spleen.

Medical Memoranda

Carotene Preparations as Substitutes for Vitamin A Preparations

Dr. H. Steenbock of Wisconsin, U.S.A., in 1919 and Prof. Hans von Euler of Stockholm in 1928 associated the carotenoid pigments of plants with vitamin A activity. The matter was settled by Dr. T. Moore of the Nutritional Laboratory, Cambridge, when he showed that yellow carotene fed to animals is converted into the colourless vitamin A found in liver oils. There are several carotenes and allied pigments, and of these β -carotene is the most effective for the formation of vitamin A, because one molecule of β -carotene plus a molecule of water can give rise to two molecules of vitamin A. A molecule of the other carotenes can be converted into only one molecule of vitamin A. Therefore it has been assumed that the carotenes can be used as substitutes for vitamin A.

In wartime, when there is a shortage of protective foodstuffs of animal origin rich in vitamin A, dietitians urge an increased use of foodstuffs rich in carotenes, such as carrots, green leaves, red palm oil, etc.

Recently attempts have been made in India and Ceylon to find substitutes for cod-liver oil, and it has been proposed to use products of red palm oil (*Elaeis guineensis*).

A new preparation has been made in Madras: it is a thick cloudy oil of a deep orange colour, and contains 516 γ per gramme of carotene, reckoned as β -carotene. It has been submitted to the following limited test in Ceylon.

Fifteen children in an orphanage who showed marked or very marked signs of phrynodermia were divided into three groups of 5 each. The first group were given approximately 30 grammes of the preparation; the second group received 30 grammes of unstandardized cod-liver oil daily; and the third group were used as controls. The children were examined weekly, and the result at the end of six weeks was as follows: 3 of the first group showed some improvement and 2 showed none; 4 of the second group were markedly improved, with considerable clearing up of the phrynodermia, and 1 was slightly improved. None of the control group showed any improvement. All the children received portions of the same diet.

Many children with phrynodermia have been treated with capsules of a fish-liver oil concentrate, each of which the makers guarantee to contain "not less than 9,400 I.U. of vitamin A activity." It has been our experience that, with a few exceptions, phrynodermia clears up in children in about three weeks when they are given three capsules daily. The international unit of vitamin A activity is 0.6 of β -carotene, and the amount in the new preparation given daily to each child was approximately 26,000 units reckoned as β -carotene. Even assuming that much of the carotene was in the form of α - and γ -carotenes the children were receiving a very considerable amount. Incidentally, although the cod-liver oil was far more effective than the preparation, it does not seem to have been of a very high standard.

DISCUSSION

Little is known concerning the absorption of carotenes from the alimentary tract or of their conversion into vitamin A in the healthy body, and still less is known of their fate in the body under conditions of disease. There may be little doubt that a healthy adult on a vegetarian diet can obtain a sufficient amount of vitamin A from the carotenes of the diet; but it does not necessarily follow that this applies to the infant or the growing child. There is a high incidence of signs of vitamin A deficiency among the poorer-class children of Ceylon, and this is especially so among the younger children and those being weaned to a more or less vegetarian diet. It seems as though the metabolism of the child's body does not quickly or readily pass from the utilization of vitamin A as it occurs in the mother's milk to the utilization of carotenes by converting them into vitamin A.

Fatal Cases of Poisoning with Sodium Nitroprusside

The following cases are worthy of record in view of the chemical compound which was the cause of death.

CASE I

The patient, a second-year probationer nurse aged 23, had had vague abdominal pain suggestive of chronic appendicitis in July, 1940. This settled down, but recurred in February, 1941, and she was to have been examined by a surgeon on February 13.

During the night of February 9 she had an attack of vomiting, but on the following day was apparently perfectly well. On the 12th she attended a lecture from 11 a.m. to noon, and at 1.15 p.m. she was heard to call out and was found leaning against the wall in one of the lavatories in the nurses' home. She was put to bed: her colour was poor, the temperature was 95° F., the pulse rate 132, and the respirations 26. She was able to answer questions, but was drowsy and had difficulty in concentrating. The pupils were slightly dilated; the conjunctival reflexes were present. She was transferred to hospital, where a diagnosis of a fit or poisoning was made. The stomach was washed out by 2.20 p.m. At 2.25 p.m. she was unconscious, and respiration gradually became slower and more laboured. At 2.45 p.m. the pulse rate had fallen to 45, the pupils were fully dilated, and trismus was present. After the stomach lavage there was some frothing at the mouth and nose. The patient remained unconscious, and she was placed in a Drinker respirator. She died at 3.45 p.m.

At the post-mortem examination the dependent parts of the body showed the characteristic bright pink coloration seen in cases of poisoning by hydrocyanic acid. There was a little frothy mucoid material in the trachea, and the upper lobes of the lungs were oedematous. The stomach contained a small quantity of partially digested food which had a definite smell, but this was not distinct enough to be identified with certainty as the smell of bitter almonds. The mucosa of the stomach, duodenum, and upper few inches of the jejunum was slightly congested, the congestion fading from the stomach to the jejunum. The vessels of the liver and kidneys were congested. As poisoning by prussic acid was not suspected no attempt was made to detect any smell when the skull was opened, and later no particular odour was noticed. Nothing else abnormal was seen except congestion of all the organs.

Analysis showed traces of hydrocyanic acid in the stomach contents, but the amount was very small, less than 1/3 grain. Sodium nitroprusside was found principally in the stomach contents but also in a specimen of vomit and in the stomach washings, the total amounting to about 6 grains. It is proposed to make a separate communication to the Analyst giving details of the method of analysis used.

CASE II

This case occurred at Rochester in 1936, but no details have hitherto been recorded.

A young surgeon was found dead in a hospital dispensary on a Monday morning, poison having been taken and death having occurred apparently on the Sunday afternoon. The case was complicated by the fact that a large dose of arsenic had been taken before the nitroprusside. Actually arsenic equivalent to over 45 grains of sodium arsenate and sodium nitroprusside amounting to over 400 grains were found in the stomach contents and viscera. Between 3 and 4 grains of hydrocyanic acid were present in the stomach. At the post-mortem examination the organs were all found to be congested. It was suggested that death must have taken place very quickly and that the arsenic played no part.

We are indebted to the matron of the hospital and to the member of the honorary staff who was called in for the clinical details of the first case.

AETIOLOGY OF CHOLELITHIASIS

Studies on the Etiology of Gallstones. A Subtilis-like Bacilli Group as an Etiologic Factor. By Karl Mårtensson. From the Department of General Pathology at Karolinska Institutet, Stockholm. *Acta Chirurgica Scandinavica*, vol. lxxxiv. Supplementum lxii. (Pp. 227; 74 illustrations.) Nordisk: Rotogravyr.

Dr. Karl Mårtensson of Stockholm has done a bold thing in publishing his *Studies on the Etiology of Gallstones*, for the discoveries which he has made are of the kind which has sometimes ultimately to be written off as a mare's nest. He began by tracing statistically a connexion between certain general disturbances and gall-stone formation, but concluded that these rather control the composition of the stone than determine its original formation, and therefore began a search for a local cause. Since the nucleus of a gall-stone often contains epithelial cells, inflammation accompanied by desquamation might well be the first stage of the process. The cause of this inflammation is identified as a spore-forming Gram-positive bacillus which can be demonstrated by special methods involving solution and sectioning of gall-stones as forming part of their stroma; it has also been demonstrated in the mucosa of the gall-bladder. It was cultivated from 33 out of 78 specimens obtained at operation or necropsy, more often from the stone itself than from the bile, never from the bile without also being present in the stones, and in no case from bile in the absence of stones. It was also found in the faeces of 5 out of 25 cases of cholelithiasis. The majority of strains of these bacilli were aerobes, and are therefore to be placed in the genus *Bacillus*, though their characters, which appear to be fairly constant apart from the small group of anaerobic organisms also recovered, are not exactly those of any named species in this genus. The inoculation of sterile bile with this organism was followed by acidification and cholesterol precipitation. Various other bacteria were also found in some of these specimens, but the newly described bacillus differs from them all in the fact that animals inoculated with it develop gall-stones. Not only did this occur in numerous animals of several species besides the obliging rabbit when the bacilli were introduced into the gall-bladder itself, but in some animals gall-stones were also formed after intravenous or subcutaneous inoculation, the addition of the bacilli to drinking-water, and even their insertion into the vagina before parturition. Further, rabbits immunized against the organism were thereby protected against cholelithiasis following inoculation into the gall-bladder. These animal lesions and the findings in human cases are profusely illustrated. No adequate criticism of such work as this is feasible in a small compass: we only feel that the facts should be stated in order that others interested in the subject may apply the author's methods, and either confirm, modify, or refute his conclusions.

PHYSIOLOGICAL REVIEWS

Annual Review of Physiology. Volume 3. Edited by James Murray Luck and Victor E. Hall. (Pp. 784. 55.00.) Published by the American Physiological Society and Annual Reviews, Inc. 1941.

The third year of publication finds this annual volume considerably augmented in size and in value. It is beyond question that our American friends have a genius for this sort of thing—collections of reviews on those branches of any subject that are of special present-day interest. This series of reviews on physiological topics made itself a place in the world's literature on physiology when the first volume

appeared, and the steady increase in the proportion of the world's physiological literature that is being published in the English language is sufficient proof of the dominance of our tongue in international scientific circles. The place formerly held by publications in German is steadily being taken by journals in English, and a majority of these come from the United States of America. The present volume is a good illustration of the type of review for which in the past Germany was held in proper esteem. Its contributors are of high repute, and the volume is an invaluable key to the current thought and investigation in the subject. Its outlook, in so far as present circumstances permit, is international, though the abundance and proximity of American work naturally make their influence felt.

It is impossible adequately to review that which is itself a very compressed review. It may be stated, however, that the bibliographical references alone form a complete and valuable survey of what is going on; the text is a sort of running commentary on this, and the index of names and subjects is exhaustive—another good feature of American publications. The following is a bare list of the contents, which shows how wide the net is spread: The Relation of Bioelectric Potentials to Cell Functioning (G. H. Bishop); The Physiological Effects of Radiant Energy (H. Laurens); Physiological Aspects of Genetics (A. H. Sturtevant); Developmental Physiology (E. Witschi); Growth (C. E. Palmer and A. Ciocco); Temperature Regulation (J. C. Scott and H. C. Bazett); Energy Metabolism (T. M. Carpenter); Respiration (C. F. Schmidt and J. H. Comroe, jun.); Physical Properties of Protoplasm (E. F. Adolph); Muscle (W. O. Fenn); The Digestive System (J. E. Thomas); Liver and Bile (W. B. Hawkins); Formed Elements of the Blood (G. M. Higgins); Heart (C. J. Wiggers and H. D. Green); Peripheral Circulation (V. E. Hall); Electrical Activity of the Brain (H. H. Jasper); The Autonomic Nervous System (D. Sheehan); The Special Senses—I. Hearing (E. Bárány), II. Visual Receptors (R. Granit), III. Vibratory Sensations and Pain (Y. Zotterman); Physiological Psychology (H. S. Liddell); Kidney (L. Leiter); Metabolic Functions of the Endocrine Glands (S. Soskin); Endocrine Aspects of the Physiology of Reproduction (O. Riddle); Reproduction in Mammals (M. H. Friedman); Bacterial Chemotherapy (E. K. Marshall, jun.); Histamine and Anaphylaxis (W. Feldberg); Exercise (A. H. Steinhaus). There can be not only very few physiologists, but also very few of those engaged on any branch of medical research, to whom some of these articles would not be valuable. The paper is matt and restful, and the type and get-up of the best.

DISEASES OF THE SKIN

Modern Dermatology and Syphilology. By S. William Becker, M.D., and Maximilian E. Obermayer, M.D. (Pp. 872; 461 illustrations in text, 32 full colour plates. 65s. net.) Philadelphia, London, Montreal: J. B. Lippincott Company. 1941.

Every professor of dermatology in America appears to think it his duty to write a textbook of skin diseases, and here is one from the University of Chicago. The authors have very rightly attempted to depart from the familiar pattern of the dermatological textbook and state that they have sacrificed comprehensiveness to a fuller discussion of those diseases which are commonly seen in the English-speaking world. They have also tried to adopt a style such as that used by a lecturer speaking to students rather than that of a compiler of an encyclopaedia.

A special feature of this textbook is a chapter on the neurodermatoses, among which are included the numerous varieties of pruritus, idiopathic chronic urticaria, alopecia areata, lichen planus, rosacea, and (rather curiously) vitiligo. But it appears that this disease is included among the neurodermatoses not because it is caused by neuro-

vascular instability but because in hypersensitive individuals it gives rise to unhappiness and neurosis. The authors also think that there is some possibility of preventing the extension of the affected area by ultra-violet rays and eau-de-Cologne. Most dermatologists will think that this is an unduly sanguine view to take. Our authors attempt to treat their patients suffering from these neurodermatoses on neurological or rather, perhaps, psychological lines. They emphasize the importance of regular and sufficient holidays, the daily nap and sunshine, natural if possible, but if not, artificial. They claim that they are more successful than the majority of physicians in dealing with this class of patient. Our authors also make a brave attempt to differentiate between the various types of eruption which are all commonly herded together under the old appellation of "eczema." In one important series of cases they follow the teaching of Kreibich, who brought forward evidence of disturbance of the cutaneous nerves, and they designate these cases as neurodermatitis, which may be either dry or exudative, and they state that such patients very rarely exhibit hypersensitiveness (or "allergy") on the application of patch tests. Their views are worthy of careful study.

Altogether this is a good textbook of dermatology; it is written in an attractive style, and, like all modern American books, is well printed and produced. A useful feature is the presentation of various subjects in tabular form, which enables the reader to get a clearer idea of the problem than he might otherwise. Among matters so treated are the causes of drug eruptions, of the chief occupational diseases of the skin, the methodical treatment of syphilis, etc. The main drawback to this book is its price, which is high, especially for students, but apart from that one may say that it is worthy of the university whence it emanates.

Notes on Books

The speedy demand for a new edition of Sir ARTHUR HURST'S *Medical Diseases of War* is the best evidence of its excellence. It has been thoroughly revised, and in view of the spread of the war to the Middle East the chapter on amoebic dysentery has been reintroduced from the 1918 version of this work, together with a new chapter on malaria from the pen of Colonel H. B. F. Dixon. Colonel Stott has contributed a new chapter on meningococcal fever, and shortly before his lamented death Dr. T. A. Ross wrote a postscript to his article on anxiety neuroses, of which he was such an admirable and successful therapist. Emphasis is also laid on digestive disorders, which have unexpectedly proved to be one of the most important medical problems of this war. Altogether a most useful book. It is published by Edward Arnold and Co. at 18s.

The Fire Protection and A.R.P. Year-Book 1941-42 is a kind of Whitaker of the fire brigade. It includes an alphabetical list of all the fire brigades and salvage corps of the kingdom, with full statistical details of equipment and operations. A directory of A.R.P. officers for every authority is another useful feature, and so is an epitome of the legislation affecting the fire service. The statutory rules and orders relating to fires are given, together with particulars of the standard specifications for A.R.P. equipment. The surprising amount of technical information embodied in this volume goes to show that fire-fighting is no longer a haphazard business but a science and discipline. One of the ironies of events is that all the records for this year-book with the material set in type were lost during the fire raid on London at the end of last December. But the data have been reassembled, and the result is a compilation which is useful to all engaged in the defence, but particularly to those called upon to deal with the menace of the incendiary bomb. It is published by Leonard Erskine and Co., Ltd., of Aldwych House, W.C.2, at 7s. 6d. free.

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY SEPTEMBER 20 1941

TREATMENT WITH BACTERIOPHAGE

The American Medical Association, among other valuable services rendered through its journal, sometimes commissions a report by recognized authorities on the status of some form of treatment. Such a report on bacteriophage treatment, by M. D. Eaton and S. Bayne-Jones,¹ appeared in 1934, and at that time we referred editorially² to the cautious and, indeed, somewhat sceptical conclusions to which these authors were led. It is now considered that a further review of the position is necessary, and this has been prepared by A. P. Krueger and E. Jane Scribner,³ whose full and thoroughly documented account of more recent work on bacteriophage is a valuable source of information apart from the conclusions they draw from it. Seven years of further work enable this review to begin with a statement of the nature of bacteriophage, and an analysis of the mechanism of its action and the factors controlling this.

Bacteriophage is not a micro-organism but a protein of high molecular weight formed from a precursor within the bacterial cell. For lysis to take place a concentration of about 100 phage units per cell is necessary. Well-founded calculations enable the concentrations attainable in a lesion by therapeutic use to be assessed, and it immediately becomes clear that even after direct application the lytic threshold is unlikely to be reached. Systemic administration assumes—in so far as therapy is based on any such reasoned assumption at all—"a chemotactic affinity of fantastic proportions between phage and pathogen," an affinity of which in fact there is no evidence. It has been found in animal experiments that phage given intravenously is rapidly removed from the circulation by the reticulo-endothelial system. But apart from loss of activity by dilution and sequestration, phage applied in any way to a bodily lesion has to operate in a medium immeasurably less favourable than a tube of culture medium. Its activity is known to be greatly impaired by the presence of dead bacteria, which adsorb it irreversibly, by leucocytes and leucocytic extracts, and by serum. These are exactly the materials of which an inflammatory exudate is composed. Thus local circumstances in the diseased tissue are "practically without exception inimical to the process of bacteriophagy." Hence it is concluded that however phage preparations may act in the body—and it is not denied that sometimes they may act—lysis of bacteria as seen *in vitro* is not the mechanism. The accepted theoretical basis of phage treatment is thus fallacious. It is also deliberately concluded that the spontaneous development of phage plays no part in natural recovery—a most important decision, setting aside an attractive

hypothesis which has captivated popular medical imagination in connexion with several diseases.

What, then, are the other effects which phage treatment may produce? There is another possibility involving a direct action on micro-organisms—namely, that in the presence of phage bacterial dissociation may occur, leading to the production of less virulent variants. That this may happen *in vitro* is known; to what extent it occurs in the body is doubtful, and an opposite effect—the production of variants of greater virulence—is a possibility of which at least one example is said to have been observed *in vitro*. There is also evidence of several kinds that phage may act as a stimulus to phagocytosis. The other effects which phage preparations undoubtedly may have all depend on impurities. The preparation is a lysed bacterial culture, and therefore contains, as well as phage itself, constituents of the bacterial cell in solution, any products of bacterial growth, and the remaining constituents of the culture medium. The intravenous injection of such a hotch-potch of materials has an entirely non-specific action in inducing a leucocytosis, and perhaps in stimulating the mechanism of resistance in other unspecified ways. But the preparation also contains the antigens of lysed bacteria, and these are calculated to excite the formation of specific antibodies. It is quite possible that bacterial antigens in this form have a more rapid and perhaps even a greater immunizing power than a suspension of the intact bacteria from which they are derived—that phage is in fact merely a means for producing a more efficient bacterial vaccine. Each of these arguments applies not only to systemic administration but to local application. Whatever view may be taken about local immunity in Besredka's sense, there is no doubt that applications of this sort to the tissues cause a reaction which is protective against infection, if only by causing leucocytic infiltration. In these authors' opinion "phage lysates in general should be agents *par excellence* for developing local immunity, since they contain several of the individual materials known to be active in this direction: it is our opinion that much of their therapeutic efficiency can be ascribed to this mechanism."

The second part of their paper is devoted to an assessment of clinical results in various conditions: here the plain facts of experimental study are exchanged for a maze of varied observations strongly coloured with therapeutic enthusiasm, forming altogether a prodigious haystack in which to seek the needle of truth. Its main subdivisions are intestinal diseases, infections of the urinary tract, superficial or local septic infections, and septicaemia. It would be neither feasible nor profitable to review in any detail the conclusions reached on this aspect of the subject. They are in any case mainly indefinite; nothing more can be said, taking reported results as a whole, than that they are suggestive of good effect. The disease for which the evidence of this is clearest is thought to be cholera. Here it should of course be remembered that conditions in the bowel are relatively free from those obstacles to phage action which are combined in concentrated form in pus. It is granted that there is clinical evidence of the immunizing and other actions by phage preparations which have already been set down as theoretically to be expected, but ques-

¹ *J. Amer. med. Ass.*, 1934, 103, 1769.² *British Medical Journal*, 1934, 2, 1110.³ *J. Amer. med. Ass.*, 1941, 116, 2160, 2269.

tioned whether these preparations excel or even necessarily equal products more specifically designed for the purpose, such as staphylococcus vaccine or toxoid and typhoid vaccine. Though it is often argued that phage preparations are at all events harmless, this is not entirely true: severe reactions have been seen which can be attributed to the presence in them of bacterial toxins or of the Duran-Reynals spreading factor. The whole of this admirable survey should have a healthy effect in a sphere of therapeutics which cries out for clearer thinking and more judicial study.

SELECTION FOR THE ARMY

Those who can recall the procedure of medical boards charged with examination of Army recruits during the last war will agree that methods have now greatly improved. The 1914-18 recruit was seen by two, or sometimes three, medical men, and the total time spent on examination, including eyesight test, in a case which presented no obvious difficulty was perhaps ten minutes. This sufficed to grade a man from A1 to C3 or to reject him entirely. The medical boards now consist of five medical practitioners, who altogether examine as a rule from 25 to 30 men during a session of two and a half hours. Each doctor sees each man for approximately five minutes, so that the full examination of one recruit occupies not much less than half an hour. The chairman of the board decides on the final grading and also whether the man should be sent to a specialist. The Select Committee on National Expenditure in its twenty-second report (H.M. Stationery Office, price 2d.) states that the examination as now conducted is fairly thorough, although there is still evidence that some physically unfit men are passed as fit. Even the extended time given to examination does not allow of any careful diagnosis to determine whether certain men who are strictly above the minimum standard are nevertheless likely to be of real use to the Army. The acceptance of unfit recruits is, of course, not only a personal misfortune to the men concerned, but may involve the State in large liabilities for pension and compensation. The committee believes that the present system leads to waste of public money and man-power and should be revised in accordance with modern medical and psychological experience, though it does not indicate the nature of the revision beyond suggesting that the boards would be much assisted in their work if they had past histories before them, especially the recruit's health records from the approved societies. Lack of uniformity between medical boards, shown by the type of man passed in one case and rejected in another, is mentioned.

The present report, however, is chiefly critical of the allocation of man-power once it has passed into the Service—not the occasional acceptance by the Army of medically unfit men, but the assignment of men to military occupations for which they are mentally ill adapted. This, with characteristic ignorance, is made the basis of an attack upon the medical profession in one of the more popular daily newspapers. Actually it is not a medical responsibility at all. After the medical

examination the recruits who reach the required standard of physical fitness are interviewed as to their preferences, and those not accepted for the other Services appear before the Army interviewing officer, who makes recommendations, generally on meagre data, as to the unit to which each man should be sent, and once sent it is very difficult to get him transferred to a unit more appropriate to his capacity. The committee suggests that when a man is called to attend the medical board his mental level should also be ascertained, so that men falling below a certain standard in this respect might be identified before being allocated to any branch of the Service. After receiving an intelligence grading they might be passed on to a depot for a probationary period where they would be further tested for vocational or other aptitudes. Some comments are made by the committee on the relation between age and proficiency in the Army. While the older men of military age have the advantage of greater experience, this is to a certain extent offset by relatively poor hand-and-eye co-ordination. Young men have proved of special value owing to their quickness of thought and action and also their greater physical fitness. It was stated in evidence before the committee that men of 18 and 19 are the most physically fit and mentally alert members of the community. The German authorities have been alive to this fact in the Hitler Youth Movement, in which youths of 17 are being given six months' intensive mechanized training. With regard to selection of officers the committee holds that while officers should, as a rule, be chosen from those whose intelligence as measured by tests reaches a certain level, the qualities essential to an officer cannot be ascertained solely by testing; therefore the system of reports by commanding officers on the suitability of men to be entered as cadets should be continued along with intelligence tests.

The system of selection by testing is new to the British Army, and could only be yielding its fullest value at the present time if it had been introduced ten or twenty years ago. In the unnatural selection of wartime there must be innumerable square pegs in round holes, but with the enrolment of men of higher ages and with more experience in every kind of civilian occupation, which is now taking place, it becomes imperative in the national interests, as well as in the interests of the men themselves, to ensure that their allocation to Army jobs is in some way related to their mental and physical capacity. The danger of enlistment at random of the mentally defective has lately been discussed in these columns. A paper by Dr. F. J. Esher opened the subject on August 9, and in some editorial comment upon it we raised the question whether a group intelligence test should not be used as a routine in all recruits. Intelligent personnel with some appropriate training could administer them, the assessment being left to the psychiatrists and trained psychologists. By such means the militarily useless and the unstable types of defective could be excluded and the stable types of higher grades allocated from the beginning to the kind of work for which they are fitted. It is not only important to avoid the insertion of square pegs into round holes, but everything possible should be done to reject rotten pegs of whatever shape.

HEALTH EDUCATION IN THE SHELTERS

Nearly a year ago Lord Horder pointed out that the air-raid shelter situation affords an opportunity for a new health education policy with a promise of success such as was never possible under pre-war conditions. Heavy bombing has deeply stirred the pool of social life; it has changed the nightly habitat of multitudes of people many of whom have had little or no experience of a well-ordered and hygienic community. The need and opportunity for education in health, in the care of children, in family diet, and in decent living standards and behaviour is written large across the shelters. How badly this education is needed is shown by the hundreds of noisy children who frequent them, the condition of the bedding, the state of cleanliness of parents and children alike, the misuse of lavatories, and the wilful damage and pilfering of which local authorities complain.

In the large shelters indirect education has been proceeding for a year now through the presence and example of doctors, nurses, and voluntary workers attached to social welfare organizations. The local authorities have also done much by providing sanitary facilities (in some instances washing facilities also), planned canteens, and medical aid posts. A governing factor in the situation is the popularity of the large public shelters as against the domestic or communal ones. People naturally insist on going where there are light, warmth, movement, social life, canteen, entertainment, and medical help. The small shelters, communal and Anderson, are used only by people who leave their homes if there is an "alert" or perhaps if heavy raiding is in progress. Shelters were designed, of course, to afford safety, but their successful use depends on certain other factors as well. There are instances where the authorities have been compelled to "build a shelter round the people" who insisted on a particular place because, perhaps, they had used it in the last war, or their neighbours used it, or they "thought it was safe." There is evidence of the continued use of condemned and forcibly closed shelters. One such was seen in the East End. The authorities had actually bricked up a certain railway arch on two occasions, but each time the bricks were pushed down by a crowbar and the people took possession, although there were very good shelters only a stone's throw away. People like the shelters where they "feel" safest, where there are a large number of their fellows, and where amenities are available, and these facts have to be recognized. The people who spend their time in the shelters would normally go to the cinema or a club or a pub: now to a large extent denied these social opportunities they will be more ready to learn of the possibilities of a new kind of social existence after the war. This is primarily a doctor's business, because only against a background of health knowledge can any real progress be achieved.

The educable material is there, but it will have to be carefully and judiciously handled. People should be encouraged (not discouraged, as they too often are) to take their children, and their own slight injuries and ailments, to the doctor and nurse in attendance. Those who are instructed to go to their own doctor or to clinic or hospital for treatment should be followed up to see that they do so. Again, to mention three specific instances, the methods followed by the Rev. W. E. Sangster of the Westminster Central Hall, to whom the Westminster City Council has given oversight of a number of shelters, the Rev. Father Groser of Stepney, and pacifist and similar organizations in various parts of London, are worthy of study. The practice of these workers is actually to live in the shelters, share the life of the shelterers, run the medical aid post and canteens, and introduce recreative and educational

influences. Shelter life, with all its hygienic hazards, affords an unrivalled opportunity for health education. This is the time to instil the principles of mothercraft, proper feeding, and a sufficiency of rest, and to deliver from the spoon-fed stage the people who have hitherto been satisfied to let the school medical service or the public health authorities do everything for them. The shelters where there is such leadership are unmistakable. If full advantage is taken of the opportunity a new pattern of community living may well take shape in these subterranean refuges that will be of incalculable value when the people once more come to live fearlessly in the light of day. No praise can be too high for the voluntary workers in the shelters. Indeed, they have received the highest of compliments, because wherever they have started something which is practical and necessary in any department of shelter life the authorities have had to recognize it.

The many thousands of pounds which have been spent in London and the big industrial cities on large air-raid shelters should surely be viewed as an investment for the post-war era, not merely as an amelioration of wartime conditions. Many of these places could be used as clinics, clubs, and gymnasiums when their present function is ended, though no one imagines that these great dormitories can be closed immediately on the signing of an armistice. They will be needed as temporary refuges while the homes of many are being built or reconditioned. But more important than any fabric will be the continuation into post-war life of the higher standards of health and hygiene and the spirit of community living now being fostered in the best shelters.

ANGLO-RUSSIAN MEDICAL CO-OPERATION

The heroic resistance of Russia in defence of her soil has stimulated various groups of workers in this country to express their sympathy and admiration in numerous ways. The most fruitful possibilities of co-operation lie in those fields where politics obtrude but little, and in medicine and in science movements are already on foot to start the collaboration that we hope will grow in intimacy after this war is over. About a fortnight ago it was announced that an Anglo-Soviet Public Relations Committee had been set up in London, with Lord Horder as president and Prof. A. V. Hill, M.P., as chairman of the executive committee, and the officers of this committee sent a telegram to the Soviet Ambassador on behalf of "members of the Conservative, Liberal, and Labour parties, scientists, scholars, religious leaders, publicists, editors, and writers." The British Association has organized a conference between representatives of Britain and the Empire, the United States, Soviet Russia, and China, to "demonstrate the common purpose of men of science in ensuring a post-war order in which the maximum benefits of science will be secured for all people." Last week a number of medical men met at the house of the Medical Society of London to discuss the formation of an Anglo-Soviet Medical Committee. At the meeting it was announced that prominent members of the medical profession had promised their warm support to a project having as its aim increased Anglo-Soviet medical co-operation. M. Maisky, the Soviet Ambassador, was present, and in a few words told the audience that he came of a medical family, and therefore had a strong interest in the medical profession. His father had been an army doctor, and his brother was at present in charge of a hospital on the Eastern front. He himself as a child had made a humble contribution to medical science by looking after the guinea-pigs in his father's laboratory. Sir Alfred Webb-Johnson, P.R.C.S., who took the chair, was elected president of the new committee, and various distinguished

medical men were elected vice-presidents. Support was promised from the medical branches of the Navy, Army, and Air Force. One practical proposal was made that translations should be made into Russian of medical literature bearing upon the war, and in this connexion Sir Philip Manson-Bahr drew attention to the valuable material that was available in the *Bulletins of War Medicine* edited by Sir Harold Scott. Whatever shape the various forms of collaboration eventually take, our Russian medical colleagues can be assured of our quick interest and deep sympathy in the terrible professional problems with which they must be faced at the moment.

RASPBERRY-LEAF EXTRACT

It is interesting to note that raspberry leaves are seeking an entrance into *materia medica*.¹ Recently Burn² and Withell³ described pharmacological effects of extracts of raspberry leaves which included the relaxation of the uterine muscle of the cat. In our last week's issue Sir Beckwith Whitehouse has presented new evidence that raspberry-leaf extract has the power of relaxing the uterus of the human subject. These clinical observations rest for the moment on two cases only, and more work is being done. The pharmacological investigation indicated that there may be more than one active substance present. Thus certain extracts when injected intravenously cause a large rise in blood pressure, though this followed a transitory fall of blood pressure due to an action on the heart. The depressor constituent, however, did not appear to be related to the substance acting on the uterus, since uterine relaxation was readily obtained when no fall of blood pressure occurred. The action on the uterus was not specific for the plain muscle of that organ, since a similar relaxation was produced on the muscle of the intestine. As Prof. J. H. Burn points out in our correspondence columns, the choice of the word "fragarine" is not altogether happy, and it would be well to wait upon the final verdict of the chemist before deciding what the active substance in raspberry-leaf extract should be called. Side by side with these scientific observations it may be noted with interest that raspberry leaves are being recommended in the daily press as a substitute for tobacco. They were commonly smoked in Germany during the last war. Those who have tried them, however, while finding them pleasant, complain that they lack tobacco's stimulating effect.

ANTI-TUBERCULOSIS WORK IN INDIA

The Tuberculosis Association of India was formed last year under the presidency of the Vicereine, the Marchioness of Linlithgow, who, as the daughter of the late Sir Frederick Milner, has a hereditary interest in anti-tuberculosis work. The association has already made good in a number of directions. It has undertaken broadcast talks, summoned a conference of tuberculosis workers, and arranged post-graduate courses for doctors—one of these courses was held in Bombay and another in Calcutta during the early part of this year, and a third will be organized in the autumn, probably at Delhi. Since the association came into existence new sanatoria have been opened at Amritsar and Quetta, eight are building, and eleven others are under consideration. Three new clinics have been opened, and thirty others, together with five tuberculosis hospitals, are planned. One of the most important events

of the year has been the opening of the Delhi tuberculosis clinic, which it is hoped will serve as a central model institution for imparting training to doctors, health visitors, and other tuberculosis workers. During the first four months of its existence 1,293 patients were treated, and the number now being seen daily is about 35. The clinic is working in collaboration with a tuberculosis hospital, with selected private practitioners of the district, and with care and after-care committees. Another important new beginning is the opening early this summer of the Kasauli Sanatorium, which is intended to teach modern methods of diagnosis and treatment to doctors and others who intend to specialize in tuberculosis. At the recent annual meeting of the association it was announced that the Government of Madras is introducing a nine-months course, leading to a diploma, in tuberculosis, and that the Bengal Government has decided to establish a sanatorium at Peshok, in the Darjeeling district. A generous donor in Calcutta has given a sum to build and equip the sanatorium. At the same meeting the medical commissioner of the association, Dr. C. Frimodt-Møller of Copenhagen, reported on his visit during the year to five Provinces and six States, when he inspected forty-five institutions and the proposed sites for a number of new ones. The association extended Dr. Frimodt-Møller's appointment for a further two years.

EXPERIMENTAL NEPHRITIS

The well-known experiments of Masugi⁴ are the only ones which have so far been successful in producing a glomerulo-nephritis in animals similar to that found in the human subject. Masugi's method was to inject into a duck an antigen consisting of ground and washed rabbit's kidney. After twenty-five to one hundred days the duck's serum is injected intravenously into a rabbit, and after an interval of from six to eight days nephritis develops in the latter animal. The commonly accepted explanation of this phenomenon is that it is allergic, and that the duck has developed antibodies which act upon the kidney of the rabbit. The experiment has been confirmed by numerous other workers, but there are difficulties in accepting the explanation that it is a simple reaction between antigen and antibody. One of these difficulties is the time factor, because reactions between antigen and antibody occur immediately. Sarre and Wirtz⁵ repeated the Masugi experiment, but injected the serum directly into one renal artery while the circulation of the other kidney was interrupted for about fifteen minutes. Only the kidney into which the serum had been injected developed nephritis. Thus the initial reaction takes place at once, and another factor is evidently needed to produce nephritis several days later. Kay⁶ suggests that this second factor depends on the development in the rabbit of antibodies against the serum proteins of the duck. Why this should be necessary is not yet clear.

Schoeber⁷ does not accept the allergic hypothesis completely, and has tried to support by experimental work the theory that glomerulo-nephritis in man is toxic in origin. He has injected into rats either plasma or serum or an ultra-filtrate of plasma (from which the proteins have been removed) obtained from human patients suffering from active nephritis, and he shows that in the majority of cases the rats develop histological changes of nephritis within four days. The experiment was not successful if the plasma was obtained from patients whose disease was no longer in

an active and progressive state. The renal changes in the affected rats were practically confined to the glomeruli, and consisted of proliferation of the glomerular cells with hyperaemia, increase of nuclei, and adhesion of the glomerulus to the capsule. This experiment appears to be the first to demonstrate in the blood of human nephritis a toxic substance capable of producing glomerulo-nephritis in animals.

VITAL STATISTICS IN SCOTLAND, 1939

The vital statistics for Scotland during 1939, a limited edition of which has now been published, are in several respects outstanding. For the first time in the history of the country the estimated population exceeded five millions. The lowest rates ever-recorded in Scotland were given by the birth rate, 17.36 per 1,000; the proportion of illegitimate births to total births, 5.97%; the death rate of 12.87 per 1,000 (with one exception); the infant mortality, 68.5 per 1,000 live births; diseases of pregnancy and childbirth, 4.49 per 1,000 live births. The marriage rate of 9.24 per 1,000 was with one exception the highest ever recorded in Scotland. Deaths from the principal epidemic diseases numbered 2,056, yielding a death rate for the second year in succession of 41 per 100,000, the smallest ever recorded in Scotland. The most frequent cause of death in this group was influenza with a death rate of 18; the next largest causes of death were whooping-cough and diphtheria with rates of 8. The death rate for measles was only 0.3, the smallest ever recorded. A new and important feature of the report was the comprehensive analysis of the 3,832 stillbirths registered during the first year of the Registration of Stillbirths (Scotland) Act. These have been tabulated by age of mother, cause, geographical divisions, month of registration, and number of previous children. Parity of birth and age of mother were correlated with stillbirths. The multiparae had a lower proportion of stillbirths than the primiparae, except under the age of 20, and the proportion of stillbirths increased with increasing age of mother. There was no evidence of a seasonal trend in the stillbirth rate. Of the 3,832 stillbirths there were 901 cases in which the cause was ill defined and 362 cases in which the cause was unknown. These high proportions may be due to novelty and may improve as the specifications become more apparent, but if no large part of the unknown group can be attributed to detectable causes, then an investigation into the factors causing stillbirths will be necessary before any improvement in the stillbirth rate can be expected.

FIFTY YEARS OF ANTITOXINS

On December 4, 1890, Behring and Kitasato published their epoch-making discovery of the nature of immunity in diphtheria and tetanus. They had shown that the serum of an immunized animal contained a substance which neutralized the toxin produced by the micro-organism, and that by it another non-immune animal could be protected not only against a lethal dose of that toxin but against the infection itself. Not only was this discovery the foundation of all future treatment with antitoxin, but its authors clearly foresaw and predicted its therapeutic consequences. The *Deutsche Medizinische Wochenschrift*, in which this announcement appeared, celebrated the fiftieth anniversary of the occasion in its issue of December 6, 1940, by reprinting the paper, apparently in its original type, inserting a full-page portrait of Emil von Behring, and publishing a series of contributions on related subjects as well as appreciations of von Behring's life and work. Aschoff's recollections of the man differ from the rest of these in

being no mere exercise in adulation: he is, indeed, a little critical, and recalls having been given antitoxin himself after contracting diphtheria from a necropsy. The immediate result was successful, but he appears to have suffered later from diphtheritic paralysis, whereas his wife and child, who also had diphtheria and received no antitoxin, made an uninterrupted recovery. Gundel writes on active immunization against diphtheria, confining himself to experiences with this in Germany; Magnus writes on the prophylaxis of tetanus; and an article by Schmidt on serum sickness is reprinted from a recent book by this author. Very strong national feeling is expressed in some of these contributions, and it is evidently a source of satisfaction under present conditions that von Behring's co-discoverer was a Japanese. This propagandist element is intensified by the introduction of a paper by Kikuth on what is really a quite unrelated subject—except that it represents another great German achievement—the action of germanin (Bayer 205) in sleeping sickness, with a pointed reference to African colonies now under foreign control. Less biased and more useful reviews of some of these subjects would have called for the more frequent citation of work done in other countries, particularly on various aspects of diphtheria immunization in Great Britain and the United States. It is contrary to the finest principles in science to allow racial prejudices to affect judgment on any man's work, and war, so far as we know, has led to no attempts in this country to detract from German achievements in medicine, or to overrate our own because they are British. It is unfortunate that this somewhat discordant element should mar a jubilee celebration which would otherwise be of the happiest kind. The profession in Germany may be assured that their colleagues in other lands accord full honour to von Behring and other great German pioneers whose work towards the end of the last century laid the foundations of modern medical microbiology.

MEETINGS AT HEADQUARTERS

B.M.A. House during the latter part of last week was a scene of unwonted activity in wartime. By this we mean visible and audible activity, for it is very far from being an idle place nowadays, as those who frequent Tavistock Square are well aware. On Wednesday, September 10, the Journal Board held one of its periodical business meetings. On Thursday, at 10 a.m., the Executive Committee met, and this was immediately followed by a meeting of the Council. At noon the Great Hall filled up for the opening of a special Conference of Representatives of Home Divisions under the chairmanship of Dr. Guy Dain, Chairman of the Representative Body. At 12.30 p.m. the President, Dr. Thomas Fraser, presided over the statutory Annual General Meeting of the Association for the year 1941, and at the end of brief formal business conferred, amid great applause, the Gold Medal of the Association upon Sir Kaye Le Fleming, whose memorable services are recorded in the book handed to him. During the resumed Conference of Representatives Sir Kaye once more showed his gift of statesmanship when the meeting found itself in a dilemma, largely brought about by the inexperience of new Representatives. At 5 o'clock the Council held another short session, when it reviewed the events of the early afternoon. The Conference went on with its programme throughout Friday, and after that was over the Executive Committee met again to consider a problem in procedure put up to Council by one of the Divisions. A full account of the first day's proceedings of the Conference of Representatives appears in our *Supplement*. The second day will be reported next week.

LONDON AIR-RAID SHELTERS REVISITED

Nine months ago an investigation was undertaken on behalf of the *British Medical Journal* into the health conditions of London public shelters.¹ It aroused a considerable amount of interest and, we believe, helped to awaken a conscience on this subject. With a view to discovering what improvements have been effected since last winter a further survey has lately been carried out during which various types of shelter in the City of London and Westminster and in about ten London boroughs have been thoroughly inspected. The investigation has also extended to seven of the principal cities of the country, and the results will form the subject of a second article. Some comments on the general lessons to be gathered from this investigation appear on another page.

Tube and Tunnel Shelters

Tube stations now used as shelters are bunked for 22,800, but ten times that number of people could shelter there, and many prefer sleeping on mattresses on the floor instead of in bunks. Although the stations used as shelters are under the control of the local authorities in whose area they are situated, they afford a good example of what can be done when the supply and installation is delegated to one authority, in this case the London Passenger Transport Board. Medical aid posts, canteen points, drinking-water facilities, and lavatories are standard at every station. In the City of London, Westminster, and St. Pancras there is now a laundry service, and at Leicester Square tube station a baggage room for shelterers has been opened, while others are being put in at stations under the Westminster Council's control. This room, where each shelterer has his "pigeon-hole," is disinfected twice a day, and the authorities believe that the bedding is kept much cleaner when dealt with in this way. At each medical aid post there are trained nurses and assistants, as well as orderlies, on duty all night, and a doctor visits during the evening. The posts have been roofed in to ensure quiet—incidentally making them rather warm—and there are bunks for treating cases of illness. Instead of the early canvas contrivances for sanitation, concrete structures have been built and mechanical ejectors installed, making a great improvement.

A criticism of the tube station shelterer, who may come from a considerable distance, was heard at Euston, where a warden complained that these people did nothing for themselves. Partly it is explained by the narrowness of the platforms and passages, which makes free movement out of the question and interferes with any community life. A further disadvantage of the tube shelter is the difficulty of ventilation during the night after the last trains have passed through. Fans are installed, but the people on the spot show a surprising unwillingness to make use of them. The non-dimming of the lights also interferes with the sleep of the shelterers, especially of the children, of whom there are far too many, and who are often seen running about at midnight. At St. Paul's tube station the medical aid post reported that something under 200 cases had been treated since January. These included a good deal of minor illness, a few cases of vertigo, and several of conjunctivitis.

Two large tunnel shelters deserve mention, one in the City and the other in Southwark. Much has been done in both to improve ventilation and sanitation, and both are bunked to take some thousands of people. The Southwark tunnel has three medical aid posts, three canteens, a play centre for children, and a space for recreation. Water-closets are being installed at intervals, but are much too close to the bunks. The lighting is fairly good, and considering the numbers who take refuge here there has been little to complain about on the score of health. The "under-fives" suffer most, tending to get bronchitis, especially those of them who return to shelter life after an infectious illness. All children under 5 in the Southwark tunnel are supposed to go to one of the medical aid posts every night for throat-spraying, and since this practice was started "throats" have greatly decreased. But the children, as their morning fretfulness indicates, are not getting enough rest. A

good deal of scabies has been noticed. Tunnel shelters are difficult to manage owing to their length and narrowness, but as time goes on better methods doubtless will emerge. There are not enough women wardens here.

Large Basement Shelters

A large City basement shelter was revisited. This was always one of the better shelters, but many further improvements have been carried out. Wooden bunks are being replaced by steel. Walls of the bays have been whitewashed. A laundry service, of which full advantage is taken, has been introduced. The canteen, run by the Shaftesbury Society, pays attention to the nutrition value of the food. Great improvements were also found in a large basement shelter in the East End, which was unrecognizable as the place seen eight months before. It had been bayed, whitewashed, and properly lighted, and water-closets had been substituted for the old latrines. There was a first-class medical aid post with a doctor and staff of nurses on duty all night, and there were two or three canteens.

The largest shelter in Marylebone is also excellent. It is air-conditioned, the walls have been colour-washed, and all pipes and fittings painted red. At a very good medical aid post nurses do their best to inculcate good habits among the shelterers. They have been very successful in arranging anti-diphtheria inoculations. The bunks in the bays are not too close together, and the water-closets and washing facilities are right away from the sleeping part. The people are allowed to keep bedding in the shelter, which is disinfected once a week. A section here is kept entirely for women.

Small Basements and Crypts

Two London boroughs, central and south-west, have concentrated on small basement shelters, sometimes reinforced basements in buildings, occasionally specially constructed semi-underground concrete structures. The central one was a two-story shelter with brick walls and concrete floors. Water-closets were installed and taps put in, but there were no arrangements for washing or heating, and no ventilation other than by the doors. The lighting also was not good. From a safety point of view, however, it was probably much better than some adjacent reinforced basements of houses. A few basement shelters seen in West London can only be described as slums. They were full of filthy bedding, the air was foul, and the walls in an appalling condition. The closets (chemical) were just inside the "front door." No one seemed to be responsible for these particular shelters.

A series of basement shelters under a row of shops in South-West London were being reconstructed and fitted with water-closets, sinks, and taps. It was stated that electric heaters had been tried in these shelters, but the people had abused the provision of points by bringing in too many fires and so causing fusing. The council is now installing tubular electric heating thermostatically controlled. These smaller shelters seemed to be very crowded because they were usually bunked to capacity. The medical aid and canteen arrangements (except in one borough) were satisfactory. Either they were visited by a doctor or nurse from an adjoining post or they contained a small first-aid point. Shelters of this type seemed to be fairly well occupied in the suburban areas by people who were evidently neighbours.

Finsbury, the only London borough which has had a definite air-raid shelter policy for some years, deserves special mention. One-half the Finsbury shelters are of concrete construction and the other half are reinforced basements, but the borough is trying to get many of the basements closed. The policy of this borough is to have concrete shelters with a high safety factor rather than dispersal in small inconvenient shelters. The policy does not end with the assurance of relative safety. For example, in the canteens iced milk, which is sold out every night, was provided during the hot weather, also national wholemeal bread sandwiches with salad fillings. Trouble had been previously experienced in getting what was considered to be proper food served in the shelters. Air-conditioning and alternative lighting are to be installed in most shelters. Water-closets are constructed well away from sleeping places. The shelters appear open to criticism only on the ground that they are too crowded with bunks, with not enough space for moving about or for

¹ *British Medical Journal*, December 7, 1940, pp. 790 and 795; December 14, p. 841; and December 21, p. 873.

recreational purposes. Here, as in other boroughs, a rise in the incidence of scabies has been noted.

Church crypts are favourite shelters and a cause of anxiety to most local authorities. Several of these were visited, but except for their more interesting architecture and the fact that there is usually a brick floor, they are much the same as the smaller basements.

Trenches and Railway Arches

The types of shelter which have caused most controversy are the specially constructed trenches and the railway arches, the latter being often taken over by the people against the wishes of the authorities. The condition of the trenches last winter is too well known to need description. Thousands of pounds have been spent in drying them out and in reconstruction, heating arrangements, and proper lighting. The best trench shelters seen were at Poplar, where they have been asphalted over the top, the walls cream-washed, electric fans, concealed lighting, and steel bunks have been put in, and altogether the appearance has been made most attractive. All the trench shelters seen in London were good, though not all had the Poplar "finish." Trenches which have proved impossible to recondition have been closed.

In the railway arch shelters also large improvements have been made. Arches have been re-roofed, in some cases re-walled and color-washed, lavatories have been installed, and medical aid posts and canteens made available. This type of shelter is extremely popular and has had to be "built round the people." The local authorities deserve much commendation on the enormous amount of work and planning which must have been put into making this type of shelter habitable.

What was described in our article of December 14 last year as the "worst shelter of all," in the East End, was revisited. This, too, has been re-roofed and drained. Cusa stoves have been installed in each arch, but unfortunately they are not in this instance successful. The arches are fairly well lighted. The lavatories are outside each arch, well away from the sleeping quarters, and the end arch is used for the purposes of a small medical aid post and a canteen. The local vicar, Father Groser, is responsible for the introduction of amenities which include a recreation room. He it was who pointed out that the people who occupy these arches have mostly only "bits of homes"—a living room, but no sleeping quarters—and therefore sleep in the shelter at night. Very many of them in their separate bunks are sleeping alone for the first time in their lives, and that, in Father Groser's opinion, may have accounted for the extraordinary lack of illness last winter.

Surface and Domestic Communal Shelters

Only two street surface shelters which were in dormitory use were seen, one in a north-west borough and the other in the east. Many street and domestic communal shelters are bunked but not in use. Some are bunked but have no lights; others, though well constructed, are just empty shells. Hundreds of these shelters have no gates or doors, with the result that they are fouled by human and animal excreta and are depositories for all the rubbish in the neighbourhood. The sanitary arrangements in them are extremely primitive. The two which were seen in dormitory use, however, were good, and, strange to say, popular, probably owing to the personnel in charge. In both cases they were a range of compartments and both had a medical aid post and canteen. Sanitation was water-borne. The sleeping bays were divided into smallish groups for families. They were bunked, but not too closely, and lights could be dimmed. Both of them had suffered from damp, but had been dried out and when visited were in good condition.

Generally speaking, domestic communal shelters are used either not at all or only on an "alert." Arrangements for keeping them clean are not satisfactory; they are left to the users, and the work does not get done. These shelters should be sprayed and cleaned out, or at least inspected, by the local authorities once a week. Many of them at present are breeding-places of disease.

Of all the types of shelters seen in London the basements of business houses, factories, or warehouses—the property of private firms—taken over by or lent to the local authority, were the most satisfactory. They proved to be better constructed and better lighted, and were usually warmed by central heating. A

member of the firm's staff is usually in attendance as warden. These shelters seem to be better cared for than any others. Much—almost everything—that has to do with the condition of a shelter depends upon the shelter warden. He is the keystone of an otherwise unsteady arch. Much also in the large shelters depends upon a shelter committee to give a lead to the users. From the point of view of sleeping, of recreation, and of such social life as is possible in these circumstances the tube stations are far behind even the small basement and trench shelters, but because depth gives a feeling of security they will continue to be largely requisitioned. New tube extensions are at present under construction, and these will afford fresh accommodation of this kind. The Ministry of Health informs us that, broadly the bunking and medical aid posts will be on the same lines as those at present in operation in the large public shelters. Work is now proceeding on reinforced street surface shelters, and it is believed that a solution has been found in the shape of a shelter much resembling in external appearance the original brick constructions, but with the walls reinforced throughout by means of steel surface rods. A shelter of this type has been subjected to a test, and its behaviour when the bomb exploded was satisfactory. There was no collapse of the structure, although it moved upwards and sideways to a maximum distance of over six feet. There was some cracking of the walls, but the steel rods in them were not broken, and no such breakdown of the structure occurred as could have caused casualties among its occupants. Another direction in which central work is proceeding is in experiments on the dust in different types of shelters and the part it may play in disseminating the organisms of disease. Experts working under the Ministry of Health are hopeful of reducing the possibility of infection which may be spread by dust before there is any winter crowding. The various methods of aerial disinfection are being explored. But the shelters are more than a winter problem. In July last, during a period of lull, there were over 100,000 people in the public shelters of London.

The warmest thanks are accorded to the officials of the various local authorities and to the workers in social welfare organizations for the facilities and help afforded.

AWARDS FOR GALLANTRY IN CIVIL DEFENCE

A Supplement to the *London Gazette* dated September 5 announces the award of the George Medal to Dr. Leonard Findlay, medical superintendent, Mill Road Infirmary, Liverpool, to Dr. Robert Wilson Wyse, resident surgical officer, Salford Royal Hospital, to Mr. D. M. Barlow, staff officer, A.R.P. Casualty Service, and to Mr. G. Aspin, leader, A.R.P. Rescue Party, Salford. The announcements read as follows:

DR. FINDLAY: "Dr. Findlay displayed outstanding courage and devotion to duty when the Mill Road Infirmary was badly damaged during an air raid. Although badly shaken and severely burned he immediately organized rescue work and personally led parties of volunteers to release persons trapped under the wreckage. He worked without ceasing throughout the night and following day, and refused to have his own wounds treated until he had accounted for all his patients and staff. Under his cool and courageous direction many lives were saved and all the patients evacuated to other hospitals."

DR. R. W. WYSE, MR. BARLOW, and MR. ASPIN: "A high-explosive bomb demolished the nurses' quarters of the Salford Royal Hospital, and several nurses were trapped under tons of masonry. Dr. Wyse led the rescue operations and, at great personal risk, reached the basement, which was in complete darkness and ankle-deep in water. Despite the danger from damaged electric cables and escaping gas he removed rubble and bricks, and was successful in extricating three nurses who, but for his gallant efforts, would have lost their lives. Another nurse was located by Staff Officer Barlow, who, in an attempt to release her, crawled under tons of debris. For hours he lay under the wreckage encouraging the nurse and moving masonry stone by stone. He was joined by Leader Aspin and, although there was danger of the collapse of about thirty tons of debris, the two men worked on without the slightest concern for their own safety. When it became clear that the nurse's arm was so badly trapped that further attempts to release it would prove fatal to the victim and rescuers, Dr. Wyse amputated the limb and the nurse was got out."

SCOTLAND'S HEALTH IN WARTIME

The health services of Scotland in the period from January 1, 1939, to June 30, 1941, are surveyed in a summary report issued by the Department of Health for Scotland. This report (H.M. Stationery Office, 4d.) is mainly concerned with the health of the people under wartime conditions and with the war emergency services of the Department. In some parts of the country the health organization and the emergency services have been severely tested by active war conditions such as heavy raids and the prolonged handicaps of black-out. The general conclusion is that in spite of wartime calls on personnel the health and social services of peacetime are being satisfactorily maintained; and the evidence to date indicates that the health of the people remains good.

Emergency Relief Organization

The heavy air raids on Clydeside in the spring of this year provided the first practical test for the Emergency Relief Organization. Following upon the lessons of these attacks the Department has maintained close touch with local authorities through personal visits, and many rehearsals have been staged to discover how services might be improved. Since the end of the period covered by the report instructional courses for workers in the Emergency Relief Organization have been organized.

Scotland possesses about 2,700 rest centres. Arrangements for the comfort of the occupants and for the provision of meals have improved steadily. Reserve stocks of equipment have been stored at various points throughout the country to meet any sudden emergency. To afford advice and assistance to persons—whether homeless or not—who find themselves in difficulty after enemy raids, information centres have been established in the large burghs, and smaller centres are being set up in small burghs and other populous areas in counties. Steps have been taken to strengthen the billeting organizations of local authorities.

Evacuation and Shelters

The first plans for the Evacuation Scheme were put into operation on September 1, 1939. A total of 174,605 people were transferred. By January, 1940, the number of evacuated persons remaining in receiving areas had fallen to 41,000. Reviews of the plans in 1940 brought new measures. The raids in the West of Scotland last spring led to a considerable increase in the numbers of persons evacuated. Since March, 1941, 12,000 school children have been transferred from Glasgow in official parties, and 90,000 persons in the priority classes have also been transferred from Glasgow to accommodation secured by private arrangement. Since May, 1941, the burghs of Greenock, Port Glasgow, and Dumbarton have been classified as sending areas and school children evacuated from them.

The health and comfort of people in air-raid shelters provided by public funds have been the responsibility of the Department since January, 1941. Improvements now being effected cover drying and ventilation, sanitation, seating, lighting, and bunking. The bunks are being supplied first of all in the smaller domestic shelters, and in addition bunks are being stored for installation in public and larger shelters should the demand arise. To ensure the maximum degree of dispersal of the population during raids the Anderson and other small shelters are being made as comfortable as possible.

The Scottish Hospitals

The hospital building programme is almost complete and the peacetime accommodation in fully equipped hospitals will soon have been increased by about 24,000 beds. These include the seven new country hospitals constructed and run by the Department of Health, as well as other institutions which have been upgraded and new hatted annexes to existing hospitals. Private houses lent to the Government have been converted for convalescent cases.

Many beds have been made available for non-urgent civilian cases so that the waiting lists of voluntary hospitals might be materially reduced. Urgent cases of ordinary sickness have never been refused admission to the Department's hospitals, but for less urgent cases an arrangement was made with the British Hospitals Association (Scottish Section) early in 1941, whereby patients on the waiting lists of voluntary hospitals might

be admitted to vacant beds in hospitals or annexes provided under the Emergency Hospital Scheme. The response to this arrangement has been slow. Up to the date of the report only about 750 waiting-list patients had taken advantage of it. This result has been described as "disappointing" by the Secretary of State, who emphasized in a recent speech the advantages to be gained by persons undergoing treatment in these magnificently equipped modern hospitals in country areas, under the care of trained nurses and under the direct control of highly qualified medical personnel. Though planned primarily for wartime use, these hospitals are substantially constructed permanent buildings.

Recent experience of heavy raiding in the West of Scotland showed that the Emergency Hospital Scheme is able to deal with considerable numbers of casualties without its resources being strained. A high degree of mobility has been achieved in casualty services by the establishment of twenty-eight mobile surgical units and five fully equipped and staffed casualty evacuation trains. To supply skilled staff for the Emergency Hospital Scheme an Emergency Medical Service was established. This provides a nucleus of whole-time resident staffs in hospitals, and the scheme is organized so that the staff of any hospital can be quickly strengthened by surgical teams from outside. The Civil Nursing Reserve was also recruited to supply additional nursing staff for emergency hospitals and first-aid posts, and for district nursing services.

In Scotland there are 271 fixed first-aid posts (for early treatment of casualties and to relieve pressure at emergency hospitals), eighty-two mobile first-aid posts, 145 public cleansing centres (to deal with gas attacks), and 652 first-aid points (serving small towns and villages). The ambulance service comprises large numbers of vehicles, of which 972 are whole-time ambulances.

Other Health Services

Six maternity homes for evacuated expectant mothers were functioning by June, 1941, and four more were held in reserve. Progress has been made in the provision of nurseries where women engaged in war work may have their children cared for. More recently, the Child Care Reserve has been formed to recruit women who are fond of children and desire to work as nursery helpers.

On the outbreak of war the evacuation scheme interrupted the school health services, and in 1940 there had to be undertaken an additional 25,000 medical inspections for the Children's Overseas Reception Board. Nevertheless, the health of the children is believed not to have suffered. Those sent out under the organized evacuation scheme have shown a noteworthy improvement, and the Department's medical staff report favourably on the healthy appearance and good nutrition of evacuated children, particularly of those whose parents have allowed them to remain long enough to benefit by country life.

In the Highlands and Islands the State-aided medical and nursing service and the air ambulance service are still operating successfully.

The incidence of only one infectious disease has been really affected by war conditions: cerebrospinal fever has risen considerably. There was a tendency to an increase in the numbers of diphtheria cases, but in recent months medical staffs have paid a great deal of attention to the immunization of children of school age, of whom over 40% have been immunized. More beds have been released for the treatment of tuberculosis, the incidence of which has been somewhat higher recently.

The Department of Health for Scotland has issued a circular drawing the attention of local authorities to the Milk (Special Designations) Amendment Order (Scotland), 1941, which has just been made by the Secretary of State for Scotland. Under the Orders of 1936 and 1938 provision was made for the process of milk pasteurization known as the "Holder" process. Difficulties due to several causes are being experienced in maintaining or replacing apparatus licensed under these Orders, but none the less it is most desirable for the safety of the milk supply that pasteurization should as much as possible be encouraged. The new Order allows local authorities to grant a pasteurizer's licence in respect of an alternative to the "Holder" process, known as the "high-temperature short time" method. The amending Order is published by H.M. Stationery Office, 120, George Street, Edinburgh, at 1d.

Nova et Vetera

THE FOLK-LORE OF PULMONARY TUBERCULOSIS

In a recent paper on this subject (*Tubercle*, 1941, 22, 55) Dr. J. D. Rolleston states that while engaged in the preparation of previous articles on the medical aspects of folk-lore (see *British Medical Journal*, 1939, 1, 995) he had been struck by the numerous popular as distinct from scientific views concerning pulmonary tuberculosis. He had therefore collected the folk-lore of this disease, most of which was concerned with its prophylaxis and comparatively little with its aetiology and symptoms. It is noteworthy that long before it was held by the medical profession to be an infectious disease, it was regarded as such in some country districts in England, as well as among the Karaya Indians and in Brazil. Among the causes of the disease in popular estimation were catching cold, inspiration of a very cold north wind, the sudden cure of skin diseases, especially scabies, and sexual excess. The last factor accounted for the administration of the testes of a fox or chicken in folk medicine long before the introduction of endocrinology by Brown-Séquard. Dr. Rolleston classified the various folk-lore beliefs and methods in the prophylaxis and treatment of pulmonary tuberculosis as follows: (1) Transfer of the disease to other persons, animals, and inanimate objects. (2) Animal, plant, and mineral remedies apart from any idea of transfer. (3) Religious factors, such as invocations, to the Trinity, Virgin Mary, and various saints, especially Pantaleon. (4) Charms of different kinds, some of which dated from Anglo-Saxon times. (5) Water in the form of drinking water and bathing in the sea, streams, wells, and fountains. (6) Miscellaneous remedies, such as the doctrine of signatures, the influence of the moon, odd numbers, and mechanical methods.

JOAN OF ARC

A gulf separates us from the Middle Ages, and at times we have to delve into psychopathology in order to understand the motives of some important movements of those days. Future generations may have to deal similarly with many of our own activities, but this does not alter the fact that our motivation is very different from that of the Middle Ages. The history of Joan of Arc is an illustration.

Her methods were those of her day; her inspiration was largely an anachronism; but in so far as she had a sense of national cohesion and destiny in a France that was still almost exclusively feudal in structure and outlook she heralded the future. She sensed the need for development of a centralized national State, and this made her a figure that neither her contemporaries nor future historians could ignore. This frail girl had a clearer vision than the learned ecclesiastics and the unlettered feudal warriors who were misruling the French provinces. The wonder is that she could impose her will on that motley crew of social pillars, plunderers, and adventurers. She did so by a method characteristic of her day. She urged national unity by presenting it as a divine command of which she was only the agent. In the Middle Ages this was sagacious statecraft. The anachronism in her actions was that she believed not only in her mission but in the origin of its inspiration. And she believed it so firmly that she could make others share her belief.

Was Joan Sane?

Historians have debated whether Joan was sane, but if Joan's sanity is in doubt the sanity of the whole of her generation must also be questioned. The sane do not follow the mentally deranged who hold a totally untenable position. An interesting approach to the problem of Joan's sanity is made by H. P. Bayon.¹ He tries to solve the issue by an analysis of Joan's behaviour in the ordinary circumstances of life, in childhood, at the hey-day of her achievement, and on her road to martyrdom. He stresses that all her actions indicate a courageous, simple

mind, and none of her recorded utterings show evidence of mental unbalance. He explains the "voices" that gave Joan her divine mission as autosuggestion occurring in an age and an environment where this was not unusual. There was no deception here, though history is still left wondering whether deceit was not practised by those who made use of Joan. She may have been a tool in unscrupulous hands, but her own approach, which merely bears the stamp of her age, reveals neither insanity nor hysteria.

A. S.

Reports of Societies

OPHTHALMOLOGICAL CONGRESS

OCULAR INJURIES IN WAR

The Ophthalmological Society of the United Kingdom held its annual congress at Cambridge on September 4 and 5, with an attendance of about eighty members, under the presidency of Dr. R. AFFLECK GREEVES. Hospitality was extended by Trinity and King's, and a very successful meeting resulted.

A discussion, contributed to by more than twenty members, was held on "Ocular Injuries resulting from the War." Mr. O. M. DUTHIE, who opened, said that ruptures had proved the most frequent of all war injuries of a serious type. Even when the injury was not severe the end-results were deplorable. Many cases of rupture, especially those due to flying glass, were virtually untreatable. Subconjunctival ruptures, with or without dislocation of the lens, were not infrequent. Dr. S. ZUCKERMAN, who restricted himself to civilian air-raid casualties, dealt with the problem of injuries supposed to be due to blast. He had studied the records of the last war, and had found nothing to suggest that there were changes in the eyeball due to blast. At relatively high pressures, only to be experienced when the casualties were very close to the bomb, changes, of which the commonest was retrobulbar haemorrhage, would be experienced, but such cases would probably be fatalities in any event. He gave an interesting account of a great deal of research work on the question of blast.

Mr. E. B. ALABASTER analysed 100 cases of eye injury admitted to a casualty hospital after air raids. Of these, 60 were cases of traumatic conjunctivitis, 21 were penetrating wounds caused by metal or glass, 6 were corneal abrasions, 5 were subconjunctival haemorrhage, 5 were injuries to the lids only, and there was one case each of central retinal block, detached retina, and orbital cellulitis. Of the 21 cases of penetrating wounds, 12 required enucleation of one eye. Mr. HERBERT CAIGER said that nothing had brought home to him the horror of this war so much as the case of a man aged 65 who was injured in a shelter last November. One eye was absent, and the man declared that it had been blown right out of the socket by blast, while the other eye showed detachment of the retina.

Several speakers mentioned cases in which there was no apparent injury to the eye except as the result of blast. On the other hand, it was suggested that the term "blast" was used wrongly. One speaker, for example, had referred to a blast injury in a patient who had been thrown 40 feet, another speaker remarking that it would be as logical to ascribe to blast the injuries received on a fall from a high roof. Mr. A. B. NUTT mentioned the desirability of the ophthalmic surgeon seeing eye cases as soon as possible after admission to hospital, before they were "lost" in the surgical wards on account of other injuries. Sometimes when there were extensive injuries to the face it was found that gross stitching with thick silkworm gut had been done without regard to alignment or normal anatomy of the part. Mr. R. C. DAVENPORT and other speakers referred to the frequency with which intra-ocular foreign bodies were found to be non-magnetic, in keeping with the low ferrous content of shell and bomb cases used in this war. Mr. VICTOR PURVIS mentioned that on the night of the great incendiary attack on London, December 29, 1940, 128 firemen were treated at Moorfields, all but four of whom had corneal or conjunctival foreign bodies

¹ *Proc. roy. Soc. Med.*, 1941, 34, 161.

and a staining of the cornea probably due to smoke-irritation. None of the 128 required in-patient treatment; and all but 24 did not need to come to hospital a second time.

Eye Protection

Sir JOHN PARSONS opened a brief discussion on eye protection in warfare, dealing with the subject only from the military point of view and giving the substance of the report on the Cruise vizor by the subcommittee of the Military Personnel Committee dealing with body armour. Sir RICHARD CRUISE said that at least 50% of eye casualties such as ophthalmic surgeons saw in the last war could be prevented by some form of practical eye protection. It had been urged against his vizor that visibility was seriously impeded, but even if that were so the vizor need not be lowered on any occasion when it was likely to handicap the wearer. Dr. HARRISON BUTLER pleaded for the use of an official vizor not only for soldiers but for fire watchers and others engaged in civilian protection, and it was remitted to the Council of the Society to consider taking up with the Ministry of Home Security the question of the issue of some form of eye protection along with the steel helmet for civilians.

Refraction under Service Conditions

Squadron-Leader J. H. DOGGART gave an interesting paper on refraction under wartime service conditions, suggesting a number of ways of facilitating refraction tests when large numbers of men awaited examination. Some discussion followed on deception by the examinee. It was the general testimony that, although malingering was frequent in the last war, it was very unusual in this, but, on the other hand, there were cases of men who tried to conceal defects of vision in order to obtain a particular job. One speaker said that it was common for the vision of recruits to improve after entry into service, so that the man who when he joined up had a vision of 6/9 was found to be 6/6 some time afterwards; but against this it was pointed out that the examiners on the two occasions were not likely to be the same person, nor the conditions of examination quite the same.

Unusual Symptoms of Migraine

A long discussion followed a paper by Dr. T. HARRISON BUTLER on unusual symptoms of migraine. Dr. Butler was of opinion that a comparatively small number of migrainous cases had an ocular origin. Headache newly arising must be due to some recent cause, and an ocular defect which had been present for some years, if not from birth, was unlikely, suddenly and independently, to give rise to it. Even large errors of refraction and muscle balance did not generally cause headache, and, moreover, if headache was present it was often not relieved by glasses. The PRESIDENT was of opinion that many headaches were wrongly put down to errors of refraction. Migraine was excited by different causes, an important one being fatigue. Another speaker, Mr. A. B. NUTT, suggested dietary deficiency as a possible cause. Lack of nicotinic acid was said to give rise to a complex series of symptoms, including headache and deafness. Mr. FRANK HECKFORD, who had kept certain records of persons said to be suffering from headaches, said that the large majority seemed to have no errors of refraction or disturbance of muscle balance. Persons specially subject to headache were young people between the ages of 15 and 25 who suffered from vasomotor disturbances, and nearly always complained of cold hands and feet and a feeling of weight on the top of the head, especially pronounced in girls during the period.

Oedema of the Macula

The PRESIDENT contributed a paper on oedema of the macula, a condition which, he thought, was always accompanied by distortion of central vision, varying in degree according to the severity of the oedema. A sense of diminution in the size of objects was also a common phenomenon. The clinical signs included loss of retinal transparency, common to all cases, but in the slighter degrees of oedema calling for very minute ophthalmoscopic examination and careful comparison with the appearance of the macula in the other eye for its detection. With regard to the ultimate clinical effects of oedema, central vision might be restored, improve up to a point, remain permanently reduced, or be destroyed as in most cases of central venous

thrombosis. Complete restoration of the normal appearance did not always mean full recovery of vision.

Other Communications

Other papers can only be mentioned. Mr. H. NEAME brought forward 17 cases of dendritic ulcer, in 8 of which there was association with herpes simplex. Mr. WILLIAMSON-NOBLE described three cases of unsealed retinal holes. His conclusion was that it was open to doubt whether the presence of a hole with a small peripheral loss of field and no interference with central vision called for operation, particularly at a time like this, when air raids might interfere with proper operative cure. Mr. FRANK LAW read a paper on squamous-celled carcinoma of the conjunctival surface of the lid—a rare condition and one in which it was difficult to determine the site of origin of the neoplasm. He described the appearance of the lesion in one case—an ulcerated area some 6 mm. across in a position just nasal to the midline. Removal was undertaken under general anaesthesia, with a good result. Mr. G. T. W. CASSELL described a case of orbital angioma. Wing-Commander KEITH LYLE some cases of diplopia due to head injury, and Mr. LINDSAY REA a specially interesting case of keratitis and its treatment by the osmotic action of warm magnesium sulphate.

Correspondence

Puerperal Tetanus

SIR,—In describing their very interesting case of puerperal tetanus Drs. Bruce Maclean and P. Challen (August 30, p. 302) state that cases of this condition are mainly described in America, France, China, and Germany, and they proceed to quote only foreign references. I am writing to draw attention to a long report upon this subject by a committee set up by the Royal College of Obstetricians and Gynaecologists which was published in the *Journal of Obstetrics and Gynaecology of the British Empire* as recently as June, 1941. This committee arose out of an inquiry addressed to the College by Sir Frederick Menzies (at that time Medical Officer of Health to the London County Council) as to the possible part played by infected dressings as a source of puerperal tetanus. The committee included among its members Prof. McIntosh of the Middlesex Hospital and Dr. Goodhart of the London County Council pathology service.

The report shows that cotton-wool, and still more wood-wool (cellulose tissue), as supplied to the public, contains many spore-bearing organisms. The lesson to be learnt from this is that cotton-wool and wood-wool must undergo thorough sterilization before being used in surgical and obstetrical dressings, but the report should be studied in detail by those interested in this work. In the past catgut has been blamed for the few cases of tetanus following "clean" surgical operations, but it seems likely that dressings rather than catgut may have been responsible for some, if not most, of these cases.—I am, etc.,

W. FLETCHER SHAW,

President, Royal College of Obstetricians and Gynaecologists
London, W.1, Sept. 9.

Raspberry-leaf Extract

SIR,—I have read with some interest the paper by Sir Beckwith Whitehouse on the action of raspberry-leaf extract on the human uterus. Having been engaged with Mr. Withell in pharmacological investigations, the positive results of which led Sir Beckwith Whitehouse to make his clinical trials, I was hoping that clearer evidence of value to patients would be obtained. The evidence, however, rests on two cases, and the record of the observations in the second case appears to me to show nothing. Even the record in the first case is not conclusive, since inhibition of uterine contractions may occur as a result of nervousness.

In the second place, some comment is surely needed on the choice of the word "fragarine" as a name for the substance which inhibits the uterine movements. *Fragaria* is the Latin name for the strawberry, and "fragarine" clearly conveys the idea that the substance is something present in the strawberry. The Latin name for the raspberry is *Rubus*. In any event, it is a good scientific rule to await the chemical isolation of the active

constituent before giving it a name, as was done by Dudley and Chassard Moir in the case of ergometrine. I trust that the name "fragarine" will be dropped.

Finally, I must make some comment on the references to me made by Sir Beckwith Whitehouse in his paper. He says that Mr. Withell "undertook to prepare extracts" as a result of his approach and that "when enough material was obtained the extracts were submitted to" me. This is not so. Mr. Withell had mentioned to me that Sir Beckwith Whitehouse had asked whether anything was known of the action of raspberry-leaf extract. Stimulated by this inquiry, I suggested to Mr. Withell that he and I should carry out an investigation, and in the initiation of this investigation Sir Beckwith Whitehouse had no share. As a matter of interest I sent him a preliminary account of our findings as they stood in March. This he has published in his paper without my concurrence and despite the fact that these observations were rendered obsolete by our later work, as described in our paper in the *Lancet*.—I am, etc.,

Department of Pharmacology,
Oxford, Sept. 13.

J. H. BURN.

Care in the Use of the Group O Card

SIR.—We wish to draw attention to the risks that may be run when the recorded blood group of a volunteer blood donor is accepted without confirmation. There are now so many members of emergency donor services available that when a volunteer is required for an urgent transfusion the chances of one with a donor group card coming forward are high. If there is extreme urgency and the donor presents a Group O card there may be a temptation to use his blood without further test. Danger is, of course, entirely obviated if a direct compatibility test is employed; but in an emergency the doctor, who often finds the collection of a sample of a patient's serum for the test a tedious affair, may be tempted to dispense with it and rely entirely on the evidence of the card that the volunteer is a universal donor. He may regard it as an additional safeguard that this donor has been used before, not realizing that the destination of the previous donation might have been a plasma or serum pool, where a knowledge of the group is immaterial and rechecking is often dispensed with.

Errors in mass-grouping have been estimated to be as high as 10% in some places, and these may be due to either technical or clerical mistakes. In our experience the commonest mistakes have arisen from the presence of cold agglutinins—Group O being reported as A, and A as AB—but we have recently had an instance of a Group AB donor being issued with a Group O card in error by the clerk. There are also many other possibilities of clerical error even with the most careful checking. Since one of the main purposes of mass-grouping in wartime is to segregate into an emergency list selected individuals of Group O who live or work near the bleeding-centres and who can be called upon at short notice, the question arises whether the issue of the Group O card should be permitted to the emergency donor without an independent confirmation of the group.

The possession of a group card gives the volunteer donor a real sense of responsibility, and it is to him a source of satisfaction to know that he is registered in a National Transfusion Service. Moreover, the card is of value when he wishes to transfer to another district, and for these reasons it would be undesirable to limit the issue of these cards in any way. We feel, therefore, that the cards of guaranteed universal donors should be clearly marked "Group O Confirmed" by means of a rubber stamp or preferably with a punch, and that this mark should have a definite significance throughout the country. The fact that the group had been checked by an accepted standard would reduce the risk to the extremely remote possibility of a repeated clerical error, and the donor could be used with confidence in an emergency. This system of double checking could, of course, be extended to all blood groups.

In conclusion, however, we wish to stress that a direct compatibility test should be made in all cases.—We are, etc.,

W. H. CANT,
Regional Transfusion Officer, Birmingham.

W. H. McMENEY,
Pathologist, Worcester Royal Infirmary.

A. G. SANDERS,
Regional Transfusion Officer, Oxford.

Hypertonic Sodium Sulphate

SIR.—I would add my voice to that of Dr. Tresilla L. Pires (September 6, p. 355) when, in writing of hypertonic sodium sulphate treatment of wounds, she pleaded for "a wider use of so simple and effective a substance."

I first learnt of this when Dr. Lyth introduced it to the profession in his presidential address to the Yorkshire Branch of the B.M.A. in 1935. I was so struck by it that I there and then decided to try it in my ophthalmic work.

My first case was one of orbital cellulitis resultant on a wound to the upper eyelid which came late into my ward. It cleared as if by magic, though too late to obviate damage to the nerve. I then tried it on corneal ulcers, including those with hypopyon, with almost invariable prompt success. At first I used it in an eyebath as frequently and continuously as the patient could be induced to apply it, but later on a pad of cotton-wool soaked in the solution with a fine wick of the wool introduced between the lids at the inner canthus. The pad is covered with some impervious substance, such as oiled silk, and is kept moist with a pipette by the nurse without moving it from the eye.

Since retiring from my hospital I have seen but little of corneal ulcer, but on my experience up to then I should invariably make sodium sulphate application my first line of attack. The cornea and conjunctiva stand the application of a saturated solution without trouble.

As to insect bites, etc., I was stung on the foot by a wasp. I put on a pad soaked in saturated solution, covered it with gutta-percha tissue, wrapped my foot in a towel to protect the bed-clothes, and went to sleep. In the morning there was no trace of swelling or other inconvenience. This had not previously been my experience with wasp stings.—I am, etc.,

York, Sept. 9.

PETER MACDONALD.

Voluntary Hospitals

SIR.—In your issue of September 6 (p. 353) Sir Frederick Menzies asks, "What are the particular virtues of the voluntary hospital system which are conspicuous by their absence in the municipal hospital system?" I should like to put forward three examples; others may add to them.

(1) *Initiative*.—Each member of the honorary staff of a voluntary hospital is free to treat his patients in the way he thinks best. It is fortunate that this has been so, or many of the greatest advances in medicine would have been stamped out as heresies before they had a chance to prove themselves. In the municipal system the amount of initiative allowed is under the absolute control of the resident medical superintendent. Many who occupy this position are men who welcome it, but there are too many others whose sole thought is that nothing shall be done in their hospital which might lay them open to criticism from outside. I cannot withhold sympathy from the latter group; if they had informed criticism alone to face there would be no excuse, but I have some knowledge of the way in which men in their position may be harassed by ignorant and ill-informed critics.

(2) *Independent Criticism by Colleagues*.—The work done by the honorary staff of a voluntary hospital is subject to open comment and criticism by colleagues who are in a perfectly independent position. In the municipal system the personal interests of the junior staff are too dependent on the good will of the R.M.S., and his position in turn is too vulnerable to lay criticism. The inevitable result is a soft pedal on all criticism and a tendency to keep any that does arise strictly within the four walls of the hospital.

(3) *Emphasis on Skill in Treating the Sick as the Highest Quality in a Medical Man*.—Under the voluntary hospital system the highest positions, the honours, and the rewards are enjoyed by those who are foremost in advancing the knowledge and practice of their profession. Under the municipal system promotion usually means curtailment of clinical work and concentration on administrative duties; moreover, the highest honours and rewards go to those who have excelled as administrators rather than to the clinicians or research workers. Were this universal it is hard to see how we could avoid a stultifying influence on the advance of knowledge; for with a few exceptions the most able and brilliant men will naturally follow the path which leads to the highest honours and rewards.—I am, etc.,

Redhill, Surrey, Sept. 13.

KENNETH WATSON, M.B.

SIR.—Sir Frederick Menzies asks: "What are the particular virtues of the voluntary hospital system which are conspicuous by their absence in the municipal hospital system?" This simple question has a simple answer: "There are none." Sir Frederick asks his friends another question: "What they mean by the best features of the voluntary hospital system." Others abler than myself will tell him what he already knows, but I would like to make my little contribution.

The best of our island institutions were founded in the past, and with the passage of time they are modified and adapted to the present age and to present purpose. In their long life they acquire a tradition and prestige which is a human spirit carried on from generation to generation by those who serve within the walls of the institution. It is independent of bricks and mortar. The Houses of Parliament may be destroyed by fire, the Bank of England may be rebuilt, but the spirit which animates these institutions survives, perhaps strengthened. The voluntary hospital system has tradition. This is the first thing.

Some of the voluntary hospitals were founded by religious orders and others by charitably disposed persons. The religious spirit survives and in some sense animates their activities, in some more and in some less, but at least in the sense that it animates the Mother of Parliaments. It is certainly evident in the vocational spirit which finds expression in the nursing staff of the voluntary hospitals, and I would say in parenthesis that the women who work in the voluntary hospitals contribute enormously to the atmosphere that pervades them. The war has brought this home to many of us. The voluntary hospital system depends to an extent on charity. It is customary nowadays to decry charity. It is, however, quite certainly blessed to give, and the impulse is love. To love one's neighbour as oneself and charity are Christian virtues, and these virtues are strong in the tradition and in the present working of voluntary hospitals. Together I account them the second thing in the voluntary hospital system, and their importance cannot be overestimated. The stark realism of Lenin and Hitler has emphasized the interdependence of religion and politics. If the peoples of the world could but accept the Christian philosophy wars would be no more. This, however, belongs to the future, because, as Mr. Wells has said, the teaching of "this Galilean is too much for our small hearts."

The third thing about the voluntary hospital system is personal service. The head of the hospital, generally called the chairman or treasurer, devotes the greater part of his life to this voluntary work. The governors, nursing and medical staff, and the employees all give personal service in varying degree without calculation as to immediate reward. This makes for a personal relationship with the patients, and gives them an affection for the institution and those who work in it. The reputation of a voluntary hospital depends very largely on the quality of the personal service which its members give.

The fourth important feature of the voluntary hospital system is the independence of its units. This makes for *esprit de corps* and encourages initiative. It creates self-reliance and self-dependence both in the institution itself and in every person connected with it. It extends to the patients, who therefore contribute to the funds of the institution. Freedom is said to be the essential feature of democracy. I believe that self-reliance and self-dependence in the great majority of the members of the State are the real foundation of democracy. Such absolutely English institutions as the voluntary hospitals are an integral part of democratic structure. Their survival contributes to the maintenance of British character and to the permanence of our Constitution.

Lastly, there is the medical work done in the voluntary hospitals. The members of the medical staffs include a selection from among the best men in the medical profession, because of the honour and advantage of being attached to a voluntary hospital and because of the effect of the institution on the character of those who work in it. Further, some of the voluntary hospitals provide members of the honorary medical staff with opportunity for teaching and research, and some members of these staffs are among the leaders of the profession, and some contribute to the advance of medicine and so add to the good name of their hospital in this or in other ways. The great majority of the members of the medical staffs are in private practice, general or specialized. This keeps them in contact with

the world at large, while it keeps their hospitals in touch with the lives of the people.

I realize shortcomings in the voluntary hospital system, but I see it improving year by year. The improvement can be quickened, and I have no doubt that if it performs its service adequately there is no danger as to its financial support. Indeed, I believe its service will be financially self-supporting if it is made good enough for those who require its help.—I am, etc.,

London, W.I. Sept. 6.

GEOFFREY EVANS.

SIR.—Sir Frederick Menzies (September 6, p. 353) asks for a list of virtues found in the voluntary hospital system but which do not occur in the municipal system. I am not among those who believe that the voluntary hospital system is indispensable, and, indeed, I hope to see very drastic reforms in the near future. There is, however, a fundamental principle which I think must not be overlooked in planning a better hospital service. At present the members of the honorary staff of a voluntary hospital are subjected to competition in order to make a living. I fully realize that this is detrimental to the efficiency of the younger members of the staff, who should be obtaining experience without being obliged to worry about making money. But such competition does help senior men to keep up to date.

Nobody outside a lunatic asylum would go into the medical profession with the idea of making a fortune, but most of us need a carrot of some kind in front of our nose, such as promotion or a livelihood, to keep us trotting in the latter years of life. There are, of course, many men for whom the thirst for knowledge is sufficient stimulus for efficiency, but the medical profession cannot rely on being composed entirely of such men.

I believe that if every municipal hospital had a paying block, and if private practice within the hospital was allowed to senior members of the staff, there would be a considerable improvement in the hospital service of the country.—I am, etc.,

London, W.I. Sept. 8.

MALCOLM DONALDSON.

SIR.—Surely Sir Frederick Menzies has been unfortunate either in the way he puts his questions or in his circle of friends. I assume he means exactly what he says in the first seven lines of the second paragraph of his letter.

"To be stared at with withering contempt" or to be "overwhelmed with a Niagara-like cataract of words which are entirely meaningless" must be a very odd experience when you seek an opinion. I must confess that so far I have never been treated like this when seeking a variety of information of all sorts. Perhaps, however, he does not mean these remarks to be taken literally. However, let me recommend that he reads the *Report on the British Health Services*, published by PEP in 1937, or the *Lancet* monograph on hospital reorganization, or, lastly, "The Case for a National Hospitals Board," by G. Stewart Smith, *Lancet*, July 26, 1941. I am sure he will find information and possibly opinions tending to supply an answer to the question he poses.—I am, etc.,

Plymouth, Sept. 8.

ERIC WORDLEY.

Future of Medical Education

SIR.—As student subscribers to the *Journal*, we would like to express our great appreciation of Mr. Donald McDonald's excellent article on the future of medical education.

It is undoubtedly desirable, as he emphasizes, that there should be a closer relation between the student's pre-clinical (and especially pre-medical) studies and those which engage his attention during the clinical period. One of us has a vivid recollection of hearing a lecturer (not in our own College) informing his botany class that knowledge of the subject-matter of his lecture that afternoon was essential for their examination, but that it did not matter how soon afterwards they forgot it, as they would have no further use for it. Such a desirable relation between preliminary and more advanced studies would, however, seem to require a rather more radical alteration of the curriculum.

We can fully endorse, too, from a little personal experience and much conversation with our fellows from other hospitals, Mr. McDonald's statements regarding the tendency of the specialist to teach from the rare case. "You must examine and learn all about this case—you'll never see another one like it" is an instruction we have heard more than once. We must, however, admit that we ourselves have been fortunate in that the

majority of our own teachers have recognized that the "every-day" case is the one that the student must know thoroughly before concentrating on the rarities. In fact, some of them have actually deplored the reputation, which students from this hospital have earned from examiners, of knowing the "small print"—sometimes to the exclusion of much that is of more practical importance. In this hospital, too, the "lecture," pure and simple, has been very largely replaced by the lecture-demonstration or clinical lecture in the ward—to the general satisfaction of staff and students alike.

On one point, however, we would, like Goethe, crave for "more light." We agree with Mr. McDonald's condemnation of the reasons for which many students enter medical schools, but fail to see how more scholarships will select students "because they will make good doctors." Mr. McDonald must know, as we do, students who can be relied on to pass any examination but whose intellectual ability seems limited to this examination "cramming." The scholarship, too, which will elicit the desirable type of temperament will be, surely, a revolutionary affair. It seems to us that a well-planned and well-administered curriculum might do much during its five to six years to mould temperament in the desired direction.—We are, etc.,

IAN A. J. MCCREADY.

St. Bartholomew's at Friern Hospital, Sept 8 R. T. ROUTLEDGE.

SIR,—May I take this opportunity to express the hope that "A Medical Student's View" on the future of medical education (September 6, p. 327) will not be accepted as the view of all students. This view is in striking contrast to that of the great teacher which precedes it, where the necessity for less instruction and more education in the wider sense is emphasized; one might be tempted to believe that the majority of students wished to be spoon-fed with courses on the evolution of behaviour, psychology, and sociology.

Early pre-clinical teaching may be "uninformative, and a deadweight on the enthusiasm" of an unimaginative student, and this may reflect on the way it is taught, but not on the inclusion of these subjects in the curriculum. If the student stops to light his pipe and think, there is more to be learnt from dissecting "parts" and reading "Gray" than can be remembered by mnemonics. Ward rounds do not provide the best opportunity for "asking questions and taking part in discussion." We are all too familiar with the type of person who asks all the questions. If the phrase "reading from textbooks has been redundant since the invention of printing" means anything, it is not in accordance with the results, whether judged from the point of view of examinations or of the ultimate production of doctors "blessed with humanity and judgment."

I hope that the future of medical education will not be dependent on more lectures and more people to answer questions. The most valuable source of education is what the student can learn for himself from his patients. The writer of the second of the two articles makes no reference to this except to say that "out-patient clinics are fairly good for this purpose if they are not overcrowded." The general out-patient clinics which I have attended have only been overcrowded with patients; let there be more time spent in bandaging cut fingers and less in listening to expert talk on obscure diseases. The experiences of the midwifery student on the district must remain an outstanding source of the type of education which is required. Are junior house appointments, when the newly qualified doctor has to make his own decisions for the first time, to be ignored as a source of education? Surely the improvement of these facilities of contact with patients is of greater importance than more teaching.

When the medical practitioner has to be the physical (and sometimes spiritual) adviser to men and women of every type the need for a broad outlook is obvious, but this is not to be learnt from a course of lectures. There is no call for a year in the curriculum to be set aside for gaining experience, for those who ask all the questions will gain nothing, and those who do not will find their experience for themselves. The student will be better able to cope with the "maladjusted, possibly mildly neurotic, patient" if he spends a proportion of his time drinking beer in low pubs than if he attended a course on "oecology."—I am, etc.,

A. P. BENTALL,
House-surgeon.

London S.W.3, Sept. 5

Medical Education, Culture, and State Aid

SIR,—While Prof. J. A. Ryle (September 6, p. 323) laments the decay of medicine as a cultural profession and is anxious to counteract this tendency, the statement is made in your leading article (p. 340) that 45% of university students are in receipt of State grants.

Is it not possible that the cultural degeneration to which Prof. Ryle bears evidence may be an outcome of this profuse State aid to entry into the profession? It must be obvious that a boy whose parents have the means to put a son to medicine will have more opportunity of exercising a choice of career than one whose career is determined by obtaining a scholarship. Culture is a process of slow and continuous growth from a very early age, largely dependent on many factors, such as environment, heredity, etc., involved in education and not necessarily associated with mere instruction and the possession of a good memory.—I am, etc.,

St. Mawes, Cornwall, Sept. 7.

B. H. SHAW.

Planning for Mental Health

SIR,—I was very interested in your leading article in the *Journal* of August 23 and the article, "Planning for Mental Health," in the same number. I have specialized in the treatment of the neuroses and psychoses since 1918, and the results of my psychotherapeutic experience may be of interest.

1. I am entirely in agreement with you that there is an immense need for preventive measures if the problem is to be dealt with at all. I have long ago come to the conclusion that this is the major need, and as the result of practical experience come to the opinion that a great amount of mental ill-health could be prevented by a judicious nation-wide propaganda and the education of prospective parents in the elements of mental hygiene in children.

2. I agree that for successful psychotherapy patients should be caught young. I have urged the need for this for years, but in practice it very rarely happens. This is the fault partly of the parents and partly of the attending doctor. I have long ago been forced to the realization that completely to cure a chronic neurosis in a person, say, over 35 years is a herculean and probably hopeless task. The most that can be hoped for is usually improvement only and/or prevention of further deterioration. This may sound pessimistic, but it is not; it is realistic, and had better be accepted to avoid future disappointment.

3. The number of doctors adequately trained in psychological medicine or having any knowledge of the mechanisms of the neuroses and psychoses is practically nil. The vast proportion of medical practitioners are sceptical of the real existence of the psychoneuroses and have no realization of their numbers, their seriousness as illnesses, their symptoms, or methods of diagnosis. They practically never refer such cases to specialists for diagnosis and treatment, and if they do it is after every form of physical treatment has been tried and failed. Frequently it is the patient or his relations who insist in the end.

4. With the exception of two or three post-war years, when there was a greater interest in the psychoneuroses, it is certain that in the last twenty years there has been no change for the better in the state of affairs described in para. 3.

5. You are right in saying that a special type of personality is needed to be successful in this branch of medicine. Infinite patience, sympathy, tact, common sense, and a complete lack of criticism are some of its ingredients. Without these, technical skill and knowledge are useless.

6. You ask whether it is possible to pick out such personalities before they become trainees. In my experience only those spontaneously take up psychotherapy who have some degree of neurosis themselves or who have been cured by psychotherapy. Within my time a number have come and gone. They could not stand the pace or perhaps the poverty. I feel sure, however, that if the teaching of psychological medicine were really adequate a number of students would make this fascinating branch of medicine their speciality and by so doing reveal the possession of a suitable form of personality.

7. In my experience the practice of psychotherapy requires more sacrifice of time and patience for less financial return and involves more disappointments than probably any other form of medicine. All one's efforts can be nullified by some un-

favourable but unalterable element in the patient's environment. I do not believe that there is a reasonable income to be made regularly except by the very few psychotherapists, and there is certainly no room for more. I do not wish to dissuade anyone from taking up this branch of medicine, but the facts are as stated. I have never made nearly as much as I made in general practice with less effort.

8. I have come to the conclusion that a knowledge of the technique of psycho-analysis is essential whatever form of psychotherapy it is intended to practise. By this knowledge alone can come an understanding of the mechanisms of neurosis and an appreciation of the nature of the underlying mental conflict. Psycho-analysis is the best form of therapy for the young. No other form can equal its results if successful, as they generally are or ought to be. For the middle-aged and elderly a combination of very superficial analysis with some form of suggestion is probably the best and only permissible form of psychotherapy. —I am, etc.,

Leeds, Sept. 1.

E. WRIGLEY BRAITHWAITE.

The Mental Defective in the Army

SIR,—Dr. F. J. S. Esher's article on this subject (August 9, p. 187) and the correspondence it has elicited show clearly how ineffective existing legislation concerned with mental defect has proved in practice in discovering mental defectives in the community, and thus, incidentally, preventing their recruitment in the Army. Dr. Allan Warner (September 6, p. 353), referring to three extreme cases quoted by Dr. Esher, asks appositely "how the education authority dealt with them at school, and expresses the opinion that "if the section of the Education Act relating to mentally defective children had been properly administered, they would have been notified to the mental deficiency authority." Dr. Warner, like myself a former education medical officer, knows very well the flaws in that administration and even in existing legislation.

There can be no possible doubt that the ascertainment of defectives in the community and the application to them of the provisions of the Mental Deficiency Act will never be adequate so long as the section of the Education Act relative to mentally defective children is not properly administered. That Act has, of course, no reference to the two lowest grades—the idiot and the imbecile—who are directly certified under the Mental Deficiency Act and who are, in any case, not so likely to be enlisted accidentally in the Army. The Education Act is concerned with feeble-minded children, for whom it is made a duty of local education authorities to provide special schools or classes. The Mental Deficiency Act imposes on education authorities the further duty of notifying to the mental deficiency authority children leaving these special schools or classes when it is thought desirable that they should be dealt with under that Act by way of supervision or guardianship or institutional care.

While it is true that most of the larger cities and towns have provided special schools sufficient at least for the education of a considerable section of their feeble-minded children, others have failed to do so, and in some areas, mostly rural, special schools or classes are not practicable. Although the Act encourages authorities not having a special school to send their children to the special schools of an adjacent area, this provision is for the most part ignored. There is the further difficulty that it is only the children who have attended a special school or class who can legally be notified under the Mental Deficiency Act. An authority that has no special school or class has, therefore, no incentive to discover its defectives and, as a rule, does not discover them.

Obviously there are two remedies for this position. One is that education authorities should be compelled to carry out their duties under the Education Act, so far as special schools or classes can be justified in their individual areas. And the second is that as special schools or classes are admittedly not possible everywhere, it should be made legal to notify any child found to be defective, whether or not he is, or has been, in a special school. The mentality of the child is the prime consideration, whatever type of school he has attended. This second provision, which would require an alteration in the existing law, would also meet the case of the child who is only discovered to be defective late in his ordinary school career—too late, perhaps, to justify admission to a special school.

This suggestion for an alteration of the law, together with others relative to the education of children of subnormal mentality, was put forward just before the outbreak of war by a committee (of which I was a member) appointed at the instance of the Central Association for Mental Welfare, representative of many bodies, social, educational, and medical, concerned with mental defect. In the report of that committee it is stated that one of the greatest obstacles to the efficiency of the Mental Deficiency Act has been this restriction upon notification of defective children.

The remedy for these difficulties is in the future. Meantime Dr. Esher and your correspondents are in search of a method of preventing recruitment of defectives unsuited for Army service which can be applied now. The examiners on a medical board are naturally chiefly concerned with physical fitness, and it is no reflection upon the profession to say that the majority of them have had no experience in the diagnosis of mental defect. As Dr. Warner emphasizes, there are no quick and easy methods of detecting mental defect except in its lowest grades. One can in a rapid survey find only grounds for suspicion, and then reference to an expert for a more definite opinion should be possible. Suspicion may be aroused by the recruit's facial appearance in some cases—so-called stigmata should be ignored—or by his general demeanour or by his sluggish responses or movements. As suggested by more than one of your correspondents, a short reading test may be given, but much will depend on the matter given to be read. There appears to be no reason why examiners on medical boards should not be equipped with a copy of Burt's standardized reading tests for this purpose.

Not every mental defective is unfit for some form of Army service, and even the expert's decision in individual cases may not be easily made. Too much significance should not be attributed to mental age. A case with a relatively high mental age approaching the normal may be quite unsuitable on other grounds—difficult behaviour, lack of initiative or staying power—while one of lower mental age may by virtue of stability be a useful recruit. For that reason I would deprecate the fixing of a minimum mental age, but I agree with Drs. W. J. S. Reid and David Russell (September 6, p. 353) that the age suggested by Dr. Esher is too high and does not admit sufficient latitude in selection. It is most important that the examiner should be able to obtain reliable information as to the possible recruit's history—school history if possible, general social reactions, success or otherwise in work. These, together with the results of personal examination by such tests as he prefers, including, of course, performance tests, should give the examiner a sound basis for decision.—I am, etc.,

Epsom, Sept. 9.

HENRY HERD.

Treatment of Impetigo

SIR,—The interesting letters on the treatment of impetigo contagiosa by Dr. F. R. Craddock and Captain M. H. L. Desmarais (September 6, p. 356) persuade me to mention one or two points in the treatment of this far too common disease. As many who suffer from it are poor, expense is a most important factor, while the national necessity for economy in chemicals must also be borne in mind. Dr. Craddock refers to 20% gentian violet—an excellent treatment; but the 2% aqueous solution of gentian violet used for years in this department is just as efficacious, is cheaper, and is less liable to irritate the skin. With this method the average time for cure is just over ten days, all types of the disease included. Squibb's compound quinolor ointment, which Captain Desmarais mentions, is invaluable, particularly for impetigoes of the scalp and for those cases of the subacute type which tend to develop into sycosis barbae, but it is expensive, and some patients' skins do not tolerate it well. The application of sulphanilamide, either in powder or paste form, gives good results, but appears to be no more efficient than gentian violet, is much more expensive, and seems wasteful at a time when supplies are required for more urgent purposes. Finally, the classic treatment with ammoniated mercury, either as ointment or paste, though often successful, tends in many instances to cause a chemical dermatitis with a spread of the infection, especially if an ointment is used.—I am, etc.,

Skin Department, Royal Infirmary,
Edinburgh, Sept. 8.

G. A. GRANT PETERKIN.

SIR.—I was interested in the number of articles on the treatment of impetigo contagiosa in your recent issues, and while I agree with continual changes in the interest of progress in the therapeutics of dermatology, do we not find that in the simple conditions like impetigo contagiosa many "new" medicaments with so many different proprietary names tend to lead us astray and into treatment which is prolonged and often costly? Why not go back to the "old" treatment taught to many of us as students and use ung. hydrarg. ammon. dil. This should be applied twice daily and only following removal of the crusts and scabs by dry hot boracic fomentations. The condition invariably clears in seven to ten days.

In children and in those adults where there is difficulty in finding the areas of infection and where there is a tendency to auto-infection, I have found that after two to three days of the above treatment the application of lotio eau d'Alibour N.F. (lotio cupro-zincica) i.d.s. has a most gratifying effect: the condition is immediately arrested and cure in ten days can be expected. The application of adhesive plaster over a wool pledget soaked in cupro-zincica, as suggested by Dr. M. E. J. Packer (September 6, p. 364), could be used in those cases where the areas are small and isolated, but I should think that adhesive plaster would tend to devitalize the healthy epidermis and so form a nidus for further infection, particularly on the face, where the condition is commonest. I agree with Captain M. H. L. Desmarais (September 6, p. 356) that rest and institutional treatment, particularly for children, help.

Might I suggest that the temperature observed by Dr. Noel C. Bleasdale (September 6, p. 363) in his cases treated with mercuriochrome may have been due to a mild streptococcal septicaemia or to a nephritis, which is a complication of impetigo.

I would like to tabulate the following few points: (1) Impetigo contagiosa is usually a mixed infection with either staphylococci or streptococci predominating—ung. hydrarg. ammon. dil. clears these where the former preponderate and cupro-zincica where the latter are in ascendancy. (2) Treatment with sulphapyridine or other sulphonamide may be necessary in resistant cases and in those cases where a temperature develops. (3) Resistant cases with a temperature should have a chemical analysis of the urine done. (4) Auto-inoculation is common, and detailed instructions must be given to avoid this, and for this reason institutional treatment with rest is often advisable.—I am, etc.,

Sheffield, Sept. 9.

E. BERSTOCK.

Bronchogenic Tuberculosis

SIR.—Your annotator has misinterpreted (p. 343) my use of the expression "bronchogenic tuberculosis" (p. 154), which was intended to indicate the mode of spread of the disease and not its origin. Although his further comments point to rather superficial reading of my paper, a few words on the use of the expression may be generally helpful. The suffix *-gen*, of Greek derivation, signifies "born" or "of such a kind" (Concise Oxford Dictionary). The bacilli which cause a fresh pulmonary lesion in an already infected person may come from the outside air (exogenous lesion), from the blood stream (haematogenous lesion), or by the bronchi from a focus which may itself originally have been aegrogenous or haematogenous. A focus arising in a bronchus gives rise to tuberculous bronchitis, which is not an essential feature of the early lesion that spreads later by the bronchi, and may itself be haematogenous in origin. From this it appears that the expression "bronchogenic tuberculosis" has no *raison d'être*. Its use, though not strictly etymologically correct, was therefore unlikely to cause confusion in connexion with the common type of tuberculosis that spreads by the bronchial system. Moreover, such an interpretation of *-gen* seems in keeping with the meaning "of such a kind." Your annotator states that "the origin of such a lesion [isolated pulmonary focus] is still obscure and may well be haematogenous." That this is a very common origin was definitely established by Pagel as far back as 1930,¹ and was clearly indicated in my paper to which your annotator refers.

I hope it will be generally agreed that a distinct term for the common type of tuberculosis that spreads by the bronchi is necessary. Three other alternatives were available. The use of "phthisis" is condemned by some because its meaning of "con-

sumption" is not specific. I frankly lacked the courage to introduce "bronchophorous tuberculosis," which would be etymologically accurate. And "bronchovectorial tuberculosis," containing a hybrid word, would have been even less acceptable. The term "bronchogenic" in this connexion is not original. Thus the distinguished American physician, James Alexander Müller, uses it in the expression "bronchogenic phthisis." If "phthisis" is rejected, "bronchogenic tuberculosis" appears to be a case of *faute de mieux*.

I should like to comment on one further relevant point. Contrast plays a very large part in radiological technique. Texture as well as size of focus matters in the final result. The same technique will show up a minute calcified focus or a small fibrotic lesion, but not necessarily a larger infiltration. Your annotator states that "the films so obtained [by miniature radiophotography] are sufficiently detailed to show even very small lesions." Does this apply to very small infiltrations? I find it difficult to reconcile his statement with that of Dr. Sparks, whose paper he quotes. "The image [of miniature radiophotography] was, in fact, reminiscent of that procurable in a chest radiograph of about twenty years ago." Careful study of the cases published in comparisons of miniature radiophotographs with full-size films fail to show among them any definite cases of early bronchogenic tuberculosis. Those workers who nevertheless affirm that miniature radiophotography is quite satisfactory for the detection of early pulmonary tuberculosis must think of "early pulmonary tuberculosis" as pulmonary tuberculosis in a person with no symptoms, or with symptoms that have not yet led him to consult a doctor. Such a definition will include many people with lesions far from early, and is therefore likely to do a disservice to the cause of mass radiography and the control of the disease.—I am, etc.,

Hounslow, Middlesex, Sept. 8.

G. GREGORY KAYE.

Cardiac Arrest during Anaesthesia

SIR.—As I intimated in my article on cardiac massage, I expected criticism. Far from wishing to evade Dr. H. J. Brennan's question, I thought that my letter of August 16 (p. 243) would have given him the data he required.

Obviously, it is ridiculous to assume that anaesthetists located in widely separated surgical centres (six English cities) are "grossly incompetent." Further, it should be obvious that these anaesthetists would employ the anaesthetic agents which are in vogue in England. In other words, my experience should represent a good cross-section of anaesthetists and anaesthetics. This being so, I am sure that Dr. Brennan will understand how impossible it is for me to state that no chloroform has been used in this or that case.

I wonder whether surgeons for whom Dr. Brennan anaesthetizes pry into the anaesthetic room and watch what drugs are being employed. I have little doubt that his surgeons also are too occupied in preparing for the operation, and I am sure they have too much confidence in Dr. Brennan's judgment to warrant such intrusion.—I am, etc.,

London, W.1, Sept. 9.

HAMILTON BAILEY.

* * This correspondence is now closed.—ED., B.M.J.

Status Lymphaticus and Sudden Death

SIR.—It has been contended that a diagnosis of status lymphaticus is not sufficient as a cause of death; but, in spite of the eminence of the members of the Committee that reached this conclusion, there are many who doubt the truth of their decision.

I have recently performed necropsy on a soldier aged 30 who collapsed and died suddenly while on duty. He was a well-built man with no history of previous illness. Indeed, he was quite famous as an athlete. The relevant post-mortem findings were as follows: narrow aorta; spleen rather larger than normal, with very prominent Malpighian bodies; mesenteric glands enlarged and numerous; two small areas of white fibrous tissue in the posterior wall of the left ventricle; and a thymus that weighed 5½ oz. (fortunately I have three witnesses to this remarkable finding.). In every other particular the body appeared to be healthy.

Is status lymphaticus to be regarded as having killed this man, or are the small areas of myocardial fibrosis to be blamed? The latter were so small that it is difficult to suppose that they had

¹ "Lungen-tuberkulose" in *Handbuch d. spec. Path. Anat. u. Histol.*, ed. Henke and Lubarsch, Vol. 3, Part 2, pp. 225, 344, 413.

much bearing on the matter; but when I came to read up the whole subject I found that Vasilu (*Man. Anat. patol. clin.*) states that in cases of sudden death of persons with status lymphaticus interstitial myocarditis (or cellular infiltration of the myocardium) is present. Unfortunately, I did not keep any portion of the heart for histological examination, either in this case or in any other case of status lymphaticus I have seen.

As far as I am aware the committee mentioned above did not investigate the structural changes in the heart; and I write this note in the hope that every case of status lymphaticus will in future be subjected to detailed histological examination.—I am, etc.,

London, W.1, Sept. 6.

A. PINEY.

The Thomas Splint

SIR,—I heartily agree with Major Hosken's remarks on the use of the Thomas splint (September 6, p. 355).

The first-aiders at my post can apply the splint in under ten minutes. They have been instructed to work in teams of two. The splint has been applied in the dark, working with gas masks on, and with the use of one hurricane lamp only. It was assumed that the electric current had failed. Just recently, at a Red Cross inspection by a well-known surgeon, one team was highly commended for the way the splint had been applied.

The practice has come in very useful, for a fractured femur was brought into the post and a Thomas splint was applied; the patient was comfortable and did very well subsequently at the hospital to which he was removed. Incidentally, this patient was so grateful that he offered £5 to the post, which, of course, could not accept the money.—I am, etc.,

Willesden, Sept. 6.

LOUIS SHELDON,
M.O. in Charge, First-aid Post.

Anglo-Soviet Medical Committee

SIR,—An Anglo-Soviet Medical Committee has been formed to arrange the interchange between the medical profession of this country and the Soviet Union of the latest material on the clinical and scientific aspects of medicine. Such an interchange can be of considerable value at the present time to members of the profession in both countries, and we believe that a large number of doctors in this country would be willing to co-operate in the work. Those interested and those prepared to assist by summarizing and abstracting English articles and translations of Russian work should write to the Hon. Secretary, Anglo-Soviet Medical Committee, c/o the Royal Society of Medicine, 1, Wimpole Street, W.1.—We are, etc.,

Obituary

HASTINGS GILFORD, F.R.C.S.

We regret to announce the death of Mr. Hastings Gilford at the age of 80. He practised for many years as a surgeon at Reading and was well known for his thoughtful writings on disorders of growth and development and on various aspects of the problem of cancer.

He was born at Melton Mowbray in 1861 and studied medicine at Guy's Hospital, whence he qualified M.R.C.S., L.R.C.P. in 1887. He took the F.R.C.S. in 1889, after working as clinical assistant at the Evelina Hospital for Sick Children. He was for many years surgeon, and afterwards consulting surgeon, to the Reading Dispensary and a vice-president of the Reading Pathological Society. During the last war he worked as surgeon-in-charge of the Sutherland War Hospital.

Hastings Gilford joined the British Medical Association in 1889 and was for years a regular participant in the scientific work of the Annual Meetings; between 1901 and 1904 he contributed six papers to the Surgical and other Sections. His book *Disorders of Post-Natal Growth and Development*, appeared in 1911; in 1913 he read a paper at the seventeenth International Congress of Medicine on "The Influence of the Ductless Glands on Development," and in the same year he was appointed a Hunterian Professor by the Royal College of Surgeons of England and lectured on "The Nature of Old Age and of Cancer." Thenceforward his mind was almost continuously occupied with the origin of tumours. His book *Tumours and Cancers: A Biological Study*, was published in 1925, and another, *The Cancer Problem and its Solution*, in 1934, and many letters from his pen on this subject appeared in the *British Medical Journal*. Relying solely on the clinical and post-mortem observations made during the last hundred years, he rejected the vast mass of information that has emerged from laboratory experiments. His view was that our civilization makes for degeneration; that everywhere around us, in our hospitals and charitable institutions, movements are at work which act benevolently on the individual but malevolently on the race; in short, that sentimentality prevails over common sense, to the detriment of civilized man. The effect of this general degeneration, he held, was to produce a degradation of cell structure, a precancerous condition in which the cells, if left to themselves, tend to die out, but under suitable stimuli take on the abnormal proliferation obtaining in cancer. In his last letter published in these columns (July 2, 1938) Mr. Gilford proclaimed anew his faith that not only were the causes of cancer to be found, but that they had already been found and were now being sorted out and investigated. "Cancer is not one disease but a vast group of diseases. Cancers are primarily of internal origin, as contrasted with the bacterial diseases, which are primarily of external origin. Cancers vary in kind with the nature or species of tissue or of animal, so that cancer of one species of tissue differs from that of another, and cancer of one species of animal from that of another species. As with the bacterial diseases, the causes in general are twofold: (a) predisposing, and (b) activating." This idea lay at the centre of an argument which he had often expounded before at great length. Brimful of his subject, he could not realize that prolixity lost him many readers.

Dr. AENEAS ROSE, medical officer of health, East Barnet, who died on August 26, was a son of the Highlands, his father having been chief forester to the Duke of Atholl. He was educated at Edinburgh University, where he graduated M.A. with first-class honours in moral philosophy, and became a master at Edinburgh Academy. While continuing to teach Rose studied medicine, and took his M.B., B.Ch. in 1906. After holding house appointments at the Queen's Hospital, Hackney, and Great Ormond Street Hospital, he settled in New Barnet, where he quickly built up an extensive practice, becoming also in 1924 medical officer of health to the urban district council. Rose was a man of brilliant attainments coupled with social charm and a gift for entertaining that made him both a delightful host and a welcome guest. Children of all ages adored him, and nothing gave him

greater pleasure than the tea-parties to which he invited his young friends in the school holidays. During the war of 1914-18 he served as a surgeon in the Royal Navy, and was for some time on the staff of Dartmouth College, a post for which he was admirably fitted. He took a very active part in the work of the Barnett Division, B.M.A., of which he was chairman in 1933-4 and 1939-41, and it was largely due to his efforts that the yearly programmes invariably contained the names of many eminent lecturers. If the annual dinner which opened the winter session was an outstanding success it was mainly because Rose had a hand in organizing it. Outside his professional activities he was an enthusiastic fisherman, and all his leisure was spent in fishing the rivers of Hertfordshire or those of his beloved Scotland. He will be greatly missed in New Barnett both by his patients and by his professional colleagues. Of few can it be more truly said: he was a brilliant scholar, a great sportsman, and a prince of good fellows.—W. G. H.

Mr. OSWALD TILSON DINNICK, F.R.C.S.Ed., who had been practising for many years at Launceston, Cornwall, died there on September 4 after a brief illness. He was born in Canada of Cornish ancestry, and graduated at Toronto University as M.B. in 1904. After holding resident appointments both in Toronto and in New York, and acting for a while as a ship surgeon, he came to this country, took the Conjoint diplomas and the Edinburgh Fellowship in surgery, and worked several years at the Royal Cancer Hospital in the Fulham Road, London. Two or three years before the war of 1914 it was discovered accidentally (in the course of a life assurance examination) that he was suffering from glycosuria, which prevented him from joining the R.A.M.C., though he actually did see some war service in a voluntary capacity under the Red Cross. Most of the war period, however, was spent in the Royal Cancer Hospital as surgical registrar, where the absence of most of the surgical staff on service gave him very wide operative experience under the tuition and encouragement of Sir Charles Ryall, then senior surgeon. After the war his illness progressed, and he was actually in coma when the first consignment of insulin reached England from Canada, just in time to save his life and allow him many years of useful service to his fellow men in Cornwall. A fine natural surgeon, and a ready-witted amusing companion, he was a very well-read and cultured man, with many outside interests as well as a first-rate knowledge of his profession: he was also well known as a raconteur. Mr. Dinnick is survived by his second wife (*née* Mitchell), also a member of our profession.

Dr. GUY EDWARD MILLS WOOD, formerly medical officer to Merchant Taylors' School, died on September 4 at Hungerford, Berks. He was born in London on February 5, 1869, and from Rugby School went to study medicine at the Newcastle-upon-Tyne College of Medicine. He took the English Conjoint diplomas and the M.B. of Durham University in 1890, and many years later obtained the M.R.C.P.Lond. Between 1890 and 1893 he held a succession of house appointments at University College Hospital and the National Hospital, Queen Square, and was then for five years senior assistant at Rainhill Asylum, Lancashire. He came to London to take up the post of resident medical officer at the Charterhouse (Sutton's Hospital); in 1913 he was appointed medical officer to Merchant Taylors' School and medical officer in London for the Merchant Taylors' Convalescent Homes, Bognor. During the last war Dr. Wood served as civilian medical officer at the Fulham Military Hospital.

The North-East Ulster Division has lost a staunch member by the death of Dr. DAVID HUEY, of whom an obituary notice appeared on September 6. S. M. B. writes: Although one of the busiest of practitioners, he had the proud record of never having missed a Divisional meeting in the period between the last war and the present one and invariably appeared fifteen minutes before the stated time of the meeting. A past chairman of the Division, for years he represented it at the Annual General Meeting. He had all the best attributes of the old family practitioner, and kept himself familiar with the modern trend in medicine. He had the distinction of becoming an F.R.C.S. of Edinburgh at the age of 66. His genial smile and bluff personality will be missed by his colleagues in Northern Ireland and by the many friends he met each year at the Annual Meeting.

The following well-known medical men have died abroad: Dr. PAUL FERDINAND SCHILDER, aged 54, clinical director in the psychiatric division of the Bellevue Hospital, research professor of psychiatry at New York University College of Medicine, and one of the founders and past president of the Society for Psychotherapy and Psychopathology; Rear-Admiral WILLIAM CLARENCE BRAISTED, F.R.C.S.Ed., formerly Surgeon-General of the United States Navy, aged 76; and Dr. JOHN JOSEPH MACPHEE, emeritus professor of neurology at the University of Vermont College of Medicine, aged 80.

The Services

CASUALTIES IN THE MEDICAL SERVICES

ROYAL NAVY

Surgeon Commander ARCHIBALD NEWLANDS FORSYTH, R.N., who is reported missing, presumed killed on active service, was the son of the late Mr. and Mrs. Alexander Forsyth of Aberdeen. He was educated at Robert Gordon's College, Aberdeen, and at the University of Aberdeen, graduating M.B., Ch.B. in 1926. Two years later he entered the Royal Navy as surgeon lieutenant, was promoted to surgeon lieutenant-commander in 1934, and to surgeon commander last year. In March, 1940, the King granted him permission to wear the Insignia of Chevalier of the Order of Maritime Merit conferred upon him by the President of the French Republic in recognition of valuable services rendered in connexion with the rescue of survivors from the French steamer *Yolande* when wrecked on the coast of Shantung, China, on March 6, 1938. Surgeon Commander Forsyth was a member of the British Medical Association. He leaves a widow and one daughter and one son.

Surgeon Lieut. RALPH MORTON CALDER, R.N.V.R., who is reported missing, presumed killed, on active service, was educated at the University of Glasgow, where he graduated M.B., Ch.B. in 1935. He had held the posts of house-physician at the Western Infirmary and the Royal Hospital for Sick Children, Glasgow, and house-surgeon at Ayr County Hospital. He was awarded a postgraduate scholarship in experimental pathology by the Medical Research Council in 1937-8, and was a University of London Graham scholar in pathology at University College Hospital Medical School. In 1939 he contributed an article on splenic tissue to the *Journal of Pathology and Bacteriology*, and as recently as August 9 this year he reported a case of allergic shock following a Schultz-Charlton test in the *British Medical Journal*. He became a member of the British Medical Association soon after qualification. On the outbreak of war he joined up for service as an officer of the R.N.V.R.

ROYAL ARMY MEDICAL CORPS

Prisoners of War

Captain Ian MacDougal Guthrie Stewart.
Lieut. Louis Falconer Smith.

DEATHS IN THE SERVICES

Surgeon Captain EDWARD BUTLER PICKTHORN, R.N. (ret.), died at Culmington, Shropshire, on August 27. He was the youngest son of the late Inspector-General Thomas Russel Pickthorn, R.N., and qualified M.R.C.S., L.R.C.P. in 1892. He entered the Royal Navy soon afterwards, became fleet surgeon in 1904 and surgeon captain in 1918. He served throughout the war of 1914-18, receiving the medals. He leaves a widow.

Lieut.-Colonel KENNET BRUCE BARNETT, R.A.M.C. (ret.), died at Beaconsfield on August 31, aged 73. He was born at Hollywood, Belfast, on September 22, 1867, and was educated at Queen's College, Belfast, graduating M.B., B.Ch., and B.A.O. of the Royal University of Ireland in 1892. He also studied in Dublin and London, and took the F.R.C.S.I. in 1904. Entering the Army as surgeon lieutenant in 1894, he became lieutenant-colonel in 1915, and retired in 1919. He served in the Tirah campaign on the North-West Frontier of India in 1897-8, and received the Frontier medal with two clasps.

The Minister of Health has issued an Order, which came into effect on August 25 (Statutory Rules and Orders, 1941, No. 1294), requiring any person employed as a nurse in a mental institution to continue in such employment until his services are dispensed with. Conditions in regard to exemption and other matters are set out in the Order, which may be obtained from H.M. Stationery Office (price 1d.).

Medical Notes in Parliament

Silicosis and Anthracosis

On September 9 Mr. J. GRIFFITHS asked the Secretary for Mines whether any further measures were being taken to prevent silicosis and anthracosis among coal-miners. Mr. GRENFELL said that in regard to stone drifts and headings the measures recommended by the Royal Commission were being applied wherever the conditions so required; but the provision of the apparatus was not enough, and there was still need not only for the managements but for the workmen and subordinate officials to see that it was used more regularly and effectively and kept in good order, and he appealed again for their co-operation. Very prolonged and thorough investigation had been directed to the conditions associated with the incidence of the disease, and the Department were hoping for enlightenment and guidance from the report soon to be forthcoming from the committee of the Medical Research Council. Meantime, the chief undertaking in the anthracite area of South Wales in consultation with the divisional inspector of mines had issued to all its officials a far-reaching code of instructions about precautionary measures, and this had been made known to the representatives of the workmen, on whose co-operation they must largely depend in seeking to bring about a change in the long-standing methods and customs of their work. He was hopeful that this scheme of co-operative effort would prove successful, although a standard set of statutory regulations might well be necessary later when the position was clearer.

Blood Transfusion

Mr. ERNEST BROWN, Minister of Health, on September 9 informed Sir Robert Gower that considerable numbers of blood transfusions, for which both blood and plasma were required, had been given in dealing with air-raised casualties and Service patients, and increasing use was being made of transfusion therapy in hospital practice generally. The existing donor panels and their associated blood stores, together with the plasma produced at the processing centres, should provide adequate resources for casualties on a considerably larger scale than were experienced last autumn and winter.

Allocation of Medical Personnel

In reply to Sir E. Graham-Little on September 11 Mr. ERNEST BROWN said the Central Medical War Committee continued to act as a supply committee in providing doctors required by the various civilian and military services. It was not in any way superseded by the Medical Personnel (Priority) Committee presided over by Mr. Shakespeare, although in selecting the individual doctors it would naturally conform with any decisions taken by the Government on the recommendation of that committee as to the order of priority in which the demands of the various services were to be met. It was not intended that an appeal from a practitioner should be entertained by the Medical Personnel (Priority) Committee.

Number of Evacuated Children.—On September 9 Mr. BROWN told Colonel Carver that the estimated number of evacuated children now in the reception areas, compared with six months ago, was as follows:

	Unaccompanied Children	Children with their Mothers
February 28	490,000	346,000
August 31	450,000	300,000

Distribution of Oranges.—Major LLOYD GEORGE announced on September 11 that a scheme had been prepared for distributing any oranges which might become available. Children under 6 would receive priority. Distribution would be limited to one or more areas in rotation, and for the first seven days after oranges were in the shops they would be available only for the children. Difficulty of distribution would occur if the oranges were sent direct to maternity and child welfare clinics.

Medical Certificates for Miners.—On September 9 Mr. T. MORRIS asked the Secretary for Mines whether his attention had been called to the refusal of medical certificates by some doctors in Wales for miners who had been ill for one day and who needed such certificates

to secure the payment of the 1s. a day attendance bonus. Mr. D. GRENFELL replied that the general question of furnishing medical certificates had been raised by the British Medical Association, and was receiving consideration by the Departments concerned. In view, however, of the decision last week regarding the payment of the bonus, the question of certificates had ceased to be important in this connexion.

Fortification of White Flour.—Major LLOYD GEORGE stated on September 10 that the proposal to add calcium to white flour had not been abandoned. Fortification of white flour with vitamin B₁ had begun in mills supplying South Wales and would be extended to other districts soon.

EPIDEMIOLOGICAL NOTES

Discussion of Tables

Owing to difficulties arising out of war conditions a considerable time-lag has existed between the publication of the weekly summary of infectious diseases and the week for which the returns were recorded. It is now possible to reduce this interval by one week, and accordingly the statements for two weeks are given this week.

The incidence of measles has continued to fall, and the number of notifications for the week ending August 30 was the lowest figure recorded in England and Wales since notification of this disease began nearly two years ago. The notifications of scarlet fever and diphtheria have shown a small increase, and mark the beginning of the seasonal rise of these diseases. At present the rising trend is shown only by the northern counties, the largest increase in both diseases being recorded in Lancashire. In Scotland the increase in diphtheria is fairly general, although two-fifths of the total cases were reported from Glasgow. Whooping-cough has remained almost stationary in England and Wales since the large decrease in the number of cases recorded in the week ending August 2. The present notifications of this disease are a little more than three times those of last year. The increased prevalence reported from Scotland was mainly due to the experience of the towns of Greenock and Glasgow. The number of notifications of cerebrospinal fever has declined, and the figure of 99 for England and Wales was the lowest since the first week of January, 1940.

Dysentery

The number of cases of dysentery has fallen during both of the weeks reviewed. The largest of the local outbreaks during the week ending August 23 were: Essex 28, all in Colchester M.B.; Gloucestershire 26 (Bristol C.B. 25); Northamptonshire 16 (Northampton C.B. 8 and Northampton R.D. 8); Suffolk 40 (Leiston-cum Sizewell U.D. 34—this district had an outbreak of 37 cases during the week ending August 2). During the week ending August 30 there were 20 cases in Bristol C.B., and this was the only large outbreak in the country. The increase in the notifications for Scotland was due to outbreaks in the counties of Lanark and Renfrew.

Poliomyelitis

The number of cases of poliomyelitis has declined during August. Only two areas had more than one case during the last week of the month—Lincoln (Lindsey): Lincoln C.B. 2; Buckinghamshire: Aylesbury M.B. 2.

Paratyphoid Fever

An outbreak of paratyphoid fever in Bristol C.B., which had its origin in a girl who handled food in a catering factory, resulted in 39 and 83 cases respectively during the weeks reviewed. In the second week the cases from Bristol were almost half of the total reported in the whole country.

Tuberculous Meningitis in South Wales

The recent quarterly report of the Cardiff and County Public Health Laboratory revealed that a large increase in the number of cases of tuberculous meningitis has occurred. The number of cases for the first six months of this year was 29, as compared with 11 and 14 for the whole of 1939 and 1940 respectively.

No. 34

INFECTIOUS DISEASES AND VITAL
STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended August 23.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included), (b) London (administrative county), (c) Scotland, (d) Eire, (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London), (b) London (administrative county), (c) The 16 principal towns in Scotland, (d) The 13 principal towns in Eire, (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

Medical News

Recruitment for the Sudan Medical Service, which has been suspended since the outbreak of the war, is to recommence. A notice of a vacancy will be found in our advertisement columns.

The address of the National Radium Commission office is now 6 Westminster Hospital, St. John's Gardens, London, S.W.1. Telephone: Victoria 8161, Extension 72.

The name of Dr. George McCracken, medical practitioner, Manchester, has been brought to notice for brave conduct in civil fence.

A sympathetic obituary notice of Sir D'Arcy Power appears in the *New England Journal of Medicine* of July 3.

A pamphlet entitled "Clothing Coupon Quiz: Answers to Questions on the Rationing of Clothing, Footwear, Cloth, and Knitting Yarn" was issued last week by the Board of Trade and is published by H.M. Stationery Office, price 2d. This provides ready reference to official rulings on the many questions put to retailers and to the Board of Trade since the introduction of the clothes rationing scheme. The coupon requirements for the clothing needs of man, woman, and child are clearly set out in tables. There is also a list of coupon-free articles.

Arrangements are being made in Eire for the manufacture of anaesthetics. For months past hospitals and chemists have found it difficult to secure adequate supplies, especially of ether.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, W.C.1.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated.

Authors desiring REPRINTS of their articles must communicate with the Secretary, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors over-seas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

ADVERTISEMENTS should be addressed to the Advertisement Manager (hours 9 a.m. to 5 p.m.). Orders for copies of the *Journal* and subscriptions should be addressed to the Secretary.

TELEPHONE No.—B.M.A. and B.M.J.: EUSTON 2111.

TELEGRAPHIC ADDRESSES.—EDITOR, *Aitology Westcent*, London; SECRETARY, *Medisera Westcent*, London.

B.M.A. SCOTTISH OFFICE: 7, Drumsheugh Gardens, Edinburgh.

QUERIES AND ANSWERS

Treatment of Phosphorus Burns

Major-General T. S. COATES, in reply to the inquiry about treating phosphorus burns (September 6, p. 363), writes: (1) Wash the burn immediately with a solution of sodium carbonate (two tablespoonfuls to a pint of water). This treatment neutralizes any phosphoric acid formed as the result of the combustion of phosphorus, and partially destroys any free phosphorus present. (2) To free the burn from all traces of phosphorus, wash with 1% solution copper sulphate. Copper sulphate combines with free phosphorus, forming copper phosphide, thus preventing further ignition. (3) Remove the resulting dark-coloured deposit with forceps, and thoroughly wash with water containing a little antiseptic. For extensive burns requiring hospital treatment, ultra-violet radiation is recommended and dressings of picric acid, etc., as for ordinary burns. Phosphorus burns suppurate much more than ordinary burns, and the healing period is usually three to four weeks.

Timepiece for Blind Person

Miss CATHERINE E. WILLIAMSON writes: In answer to "Inquirer" (August 16, p. 254), if he would get into touch with the National Institute for the Blind in London he would receive full particulars as to the watches which were supplied in the last war for members of His Majesty's Forces in connexion with St. Dunstan's Hostel for the Blind in Regent's Park. These watches were inexpensive, rather large in size; the face was covered, and upon pressing a spring above the winder the face opened and disclosed the time, marked

by raised dots on the dial. I worked for three years at St. Dunstan's, and observed that these watches could be used by all types of cases, even those who were extremely badly injured and unable to lead a normal life. They were also used effectively by those who were slow of thought and perhaps not so well educated as others.

LETTERS, NOTES, ETC.

Abortus Fever and Sulphapyridine

Dr. J. WHITTINGDALE (Sherborne) writes: Since my note on the response of *Br. abortus* infection to sulphapyridine (August 9, p. 210) has provoked comment, may I be permitted to reply. The patient has remained well, and one may suppose that the dose of sulphapyridine effected a *sterilisatio magna* in this instance. Sir Weldon Dalrymple-Champneys, whose interest in this disease is well known, has been kind enough to inform me that of the reported cases that have been treated with the drug about 50% have apparently been cured. In this "vale of small dairies" cases of human infection with *Br. abortus* are not infrequent; it is therefore encouraging to be able to hope for a proportion of cures by means of a new drug, in place of the former regime of bed, with occasional doses of boiled milk intramuscularly.

Red Cross Work in Abyssinia

Red Cross work in Abyssinia is being carried out by a unit consisting of a medical officer, two surgeons, four Red Cross and St. John nurses from England, and native dressers. Dr. A. J. Last, the medical officer to the unit, wrote on June 27 to the Deputy Commissioner of the British Red Cross Society, Khartum: "The larger towns . . . are staffed by military doctors and the original Italian doctors. The latter cannot be sent to outlying districts, but must be kept in the larger towns on account of their personal safety. Tigre, on the other hand, had one Italian doctor only—in Adowa—and he was frightened and wanted to leave. . . . Dr. Gurney and I came to Adowa on June 13. We have taken over from the Italian doctor a former military hospital of some 200 or more beds. It is poorly equipped and staffed with incompetent native dressers. We have already begun to reorganize the place. In addition we see nearly 100 out-patients a day in the civil dispensary."

"Relaxation"

Dr. W. NUNAN (London, W.1) writes: Not being an Olympian, either as a permanent resident or in the guise of a tourist or passing explorer, but as a humble student of the literature and practice of what should be, and will be, an integral component part of the medical curriculum, may I draw attention to the airiness of the use, abuse, and ill use of the word "relaxation" in the literature of psychotherapy. A few recent examples of the nonchalant dismissal of the question of relaxation must suffice for my present purpose. In the communication of Majors F. L. McLaughlin and W. M. Millar (August 2, p. 158), which has given rise to this discussion, the authors wrote somewhat as follows: "Having placed the patient in a state of relaxation, etc." In a recently published book on the war neuroses one of the distinguished contributors to the symposium writes: "I get the patient to relax" (*sic*). Such quotations could be multiplied indefinitely, but the point is raised. One hears daily of such phrases, used by medical men to patients, as "You must try to relax," "You must relax," "Relax all your muscles," and so on. Patients say, "I cannot make myself relax," "I try to relax." The outstanding state of such patients is one of anxiety, and the anxious patient is tense. He tries to relax. He fails, because he becomes even more tense—trying and relaxing being "opposite numbers." A very contradiction in terms. His doctor, however, has insisted that the patient must relax—and the law of reversed effort at once applies. *Quis custodiet ipsos custodes?* The anxious one, indeed, does not relax even when he sleeps, and so is "more tired in the morning than when he went to bed." Naturally, because he has worked a "double shift." Perhaps these few incoherent remarks, touching lightly on the outside edge of a large, complicated, neglected subject, put up as a target, *ballon d'essai*, or what not, may draw some (informative) fire. What is relaxation? How is it obtained? Has one not seen exhausted soldiers—landed from Dunkirk and all that—lying on railway sidings, platforms, trucks, lorries, in waiting rooms, anywhere, everywhere—asleep and tense? The cat on the hearthrug, the tired dog, can relax. *Homo sapiens* cannot relax automatically. He must, alas! be taught.

Corrigendum

In his letter on the treatment of impetigo contagiosa (September 6, p. 356) Dr. F. R. Craddock is made to say that he uses a 20% solution of gentian violet. This should have read 2%. Dr. Craddock states that he has never attempted to use gentian violet in a solution stronger than 5%.

REHABILITATION OF INJURED AIR CREWS

BY

Flight Lieutenant R. N. HOULDING, M.B., B.S., F.R.C.S.Ed.

Medical Officer in Charge of Rehabilitation of Orthopaedic Casualties at an R.A.F. Hospital

Flying accidents are associated with peculiar injuries, many of which are rarely encountered in civilian practice. When the flight of a machine is suddenly arrested by impact with the ground it is only to be expected that those portions of the body which are in contact with or are attached to the machine will be subjected to the greatest stresses. The incidence of injuries of the feet and legs is high because they are less well protected against missiles than the rest of the body, and the small bones of the feet are liable to be fractured by impact against the rudder-bar. In the days when machines were not fitted with safety harness the skull was often smashed against the instrument panel. The safety harness has saved many lives, but is associated with another injury—compression fracture of the spine due to hyperflexion at the level of the retaining straps. Gunshot wounds produce a number of interesting peripheral nerve lesions. Petrol has caused many cases of severe burning of the face, hands, and legs, for some of which tannic acid treatment has proved quite unsuitable. Internal derangement of the knee-joint is a frequent cause of disability, due to lesions of the menisci and of the lateral and cruciate ligaments. The treatment of these casualties aims at the restoration of complete or maximal function, and the criterion of treatment is the category of the patient when he returns to his unit. He may be fit for full operational or restricted flying duties or fit only for ground duty. Every effort is made to make him fit enough to take to the air again, and many patients who might be discharged to ground duty are kept in hospital until maximal function has been regained.

If function is to be restored in the shortest possible time muscular wasting and joint stiffness must be prevented. Union of a fracture in perfect alignment means little to a patient until he has regained the synergic activity of his muscles, and recovery from paresis of a muscle group is of little avail if the joint which it activates has become stiffened. Muscles cannot be synthesized, and their power and tone can only be regained by voluntary contraction and relaxation. Progressive remedial exercises form a basis for treatment, but the willingness of the patient to contract and relax the affected muscles at all hours of the day, wherever he may be, is the real key to success.

The value of organized rehabilitation of orthopaedic casualties has already been established by such pioneers as Mr. H. E. Griffiths at Greenwich, Dr. H. E. Moore at Crewe, and Mr. E. A. Nicoll at Mansfield. Mr. R. Watson-Jones has stressed many times the importance of rehabilitation, and his endeavours have not been without result in the Royal Air Force.

General Organization

Having received the necessary surgical treatment in an orthopaedic hospital, casualties are transferred to one of

several rehabilitation centres as soon as they have recovered sufficiently to become ambulant. The rehabilitation department attached to this hospital is contained entirely within a very large gymnasium, so that, having entered, patients have no occasion to leave until the end of the morning. The keynote of treatment is activity, in the form of progressive remedial exercises and games. The onus of recovering the function of an injured part is thrown on to the patient. The nature of his lesion is explained to him simply, and he is told what to do in order to overcome it. Passive treatment in the form of massage and electricity is avoided unless definitely indicated. By recording daily the range of movement of a stiffened joint with an angle

FIG. 1.—Suggestion and Co-operation! (The notice on the wall reads: "We cannot cure your weak muscles and stiffened joints, but we can show you how to cure them yourselves—and it is up to you to pull your weight.")

measurer, or the strength of a wasted muscle group against the resistance of weights running over pulleys, the patient becomes interested in overcoming his disability and enthusiastic over his progress (Fig. 1). Having gained his co-operation, it remains only to supervise his progress and to ensure that his activities are graduated. The progress made by every patient is recorded weekly in a folder, which has followed him from the R.A.F. hospital in which he received his initial treatment and which contains prints of the pertinent radiographs. This folder is subsequently returned to the surgeon who performed the initial operation.

The rehabilitation department is in the charge of a medical officer, who is assisted by a physical training officer, a sergeant, and three masseuses. The department is run in close collaboration with the sports officer, who organizes all kinds of games of a competitive nature for those in

walking plasters as well as for those who are nearly fit. The gymnasium contains a small but adequate four-cubiced physiotherapy department, the medical officer's office, a milk-bar at which the patients obtain some compensation for their expenditure of energy, and cloak-rooms. The floor space, approximately ten square feet per patient, is divided into four parts: the two largest areas are used for the general remedial classes and for special remedial exercises, the third area is used for skittles and other games, and the fourth is opposite the milk-bar and contains chairs and tables at which the patients may rest.

Every orthopaedic patient performs at least two sessions of special remedial exercises, mostly of a non-weight-bearing character, under individual supervision by a masseuse. When muscular tone is regained he joins the "nearly fit" class, in which he performs general remedial exercises of a muscle-developing nature and swimming, in addition to his special exercises, which he is encouraged to perform at every opportune moment throughout the day. Finally he graduates to the "fit" class and participates in all organized activities. The general remedial classes are run concurrently and last for three-quarters of an hour. They are followed by a ten-minutes rest interval and then by competitive games such as skittles and volley-ball; both classes then adjourn to the swimming-bath.

During the afternoon golf, tennis, swimming, and volley-ball tournaments are arranged by the sports officer, who is advised as to what each patient should and should not do. It is not always appreciated that dancing has considerable remedial value.

Occupational therapy is not employed to any great extent, since it is considered that more improvement is made in the early stages of treatment by encouraging the patient to concentrate on overcoming his disability by working away at it all day long. In the later stages the patient's attention is diverted from his injured part by participation in competitive games. Patients do not undergo vocational training whilst at this hospital.

The Need for Individual Supervision

In the words of Dr. Moore: "A certain percentage of injured persons will work out their own salvation after receiving the necessary surgical treatment, with little or no help and without any special prolongation of incapacity. However, there will always be quite a fair percentage who will require something more if they are not to drift and greatly prolong their disabilities. This is due to many causes, of which the chief are failure to get over their earlier difficulties, all kinds of retarding psychological factors, apathy, a desire to escape return to their former duties, and so on. Consequently individual supervision of their progress is an essential part of their treatment."

A patient who is left to his own devices after receiving surgical treatment will quite naturally be fearful of exerting too much activity rather than too little. It is therefore most important that he should realize that the function of a plaster cast is not to prevent him from using an injured part but to enable him to use it to the greatest extent that is compatible with immobilization of the fracture. If the plaster is properly applied and remains intact it will immobilize the fracture whatever the patient may do. Supervision is necessary to ensure that the plaster does remain intact and comfortable and that the patient does make frequent use of every joint which is not necessarily immobilized.

Manipulation and arthrotomy are followed by effusion into the joint and surrounding tissues, and if the effusion is allowed to persist adhesions and wasting will develop rapidly. By means of teaching the patient to contract the

muscles which activate the affected joint before the operation, and by ensuring that he contracts them at frequent and regular intervals after the operation, the duration of incapacity is considerably shortened. Wasting and loss of tone of the quadriceps femoris muscle is of common occurrence and is apt to be associated with pain and effusion in the knee-joint if the patient performs too violent weight-bearing activity. This is because the lateral ligaments of the knee-joint were never intended to withstand strains in a mechanical sense but to evoke increased tone in the quadriceps muscle whenever they are subjected to tension. Should the quadriceps, "the guardian of the knee-joint," be weakened, the lateral ligaments may easily be stretched and cause effusion and pain, which is liable to keep the patient awake at night and is to be distinguished from stiffness on awakening, which wears off with exercise. Without supervision a patient with wasted thigh muscles may either be fearful of exerting sufficient activity to regain the strength and tone of the quadriceps or may exert too much weight-bearing activity, so that in either event the vicious circle of wasting and effusion will become chronic and incapacity is unnecessarily protracted. With supervision excessive muscular wasting is avoided and, by restricting activity to non-weight-bearing exercises until muscular tone is regained, the period of incapacity is minimal.

It is most important to treat the patient as well as his lesion and to ferret out any "fears" which he may hide in the back of his mind. A careless statement such as "he will never fly again," if overheard by the patient, may greatly retard his progress by destroying his will to recover. Daily observation of progress engenders optimism, and the progress made by others, in addition to suggestion by posters and by the staff, ensures co-operation from the patients. Compulsion is seldom necessary, and is avoided to the greatest possible extent because it tends to evoke an attitude of obstinate resistance. Before discharging a patient to flying duties it is important to ensure that he has regained confidence in his ability to perform all normal activities. A patient who has regained full movement and muscular tone after excision of the patella may yet be fearful of running. Encouragement and participation in competitive games will overcome this natural phobia.

Physiotherapy

Physiotherapy is of great value for selected cases. It is a form of passive treatment and as such is given sparingly, because some patients are only too happy to lie at their ease on a couch and receive treatment which, for remedial purposes, is a poor substitute for their own activities. Warmth facilitates the movement of any joint by inducing hyperaemia and relaxation, and the only problem is how to direct the heat where it will do most good. A hot bath, a radiant-heat cradle, and a diathermy set each have their particular uses, but in the rehabilitation department only radiant heat is used to loosen up stiffened joints before starting remedial exercises. Faradism is used only to assist a patient to acquire the knack of contracting muscles that are very much wasted, and once he has learnt to do this the faradism is discontinued, because it is considered better to avoid passive treatment and to encourage the patients to regain muscular strength and tone by their own exertions. Galvanism serves to reassure a patient with a peripheral nerve lesion that the paretic muscles will still contract, and is also of some value for the dispersal of static congestion. An experienced masseur is able to loosen muscular adhesions by deep massage, but this treatment is seldom necessary if the patient has contracted his muscles at regular and frequent intervals throughout any period of necessary immobilization.

Patients perform their remedial exercises under the supervision of a masseuse, and this arrangement is found to be more satisfactory than to use a specially trained physical training instructor for exercises and restrict the masseuses to physiotherapy, because otherwise certain patients will tend to evade the physical training instructor for more pleasurable treatment at the hands of the masseuse. It is probable that masseurs are more suitable for the treatment of non-commissioned ranks, but I believe that masseuses are better able to obtain the co-operation of young officers.

Fractures

For the purpose of rehabilitation, patients with fractures fall into two groups—those who are uniting and require immobilization, and those who have united and require remedial treatment to restore the strength and tone of their muscles and the movements of their joints. Obviously effective treatment of the first group will minimize the treatment required by the second group and will curtail the period of incapacity.

There is no really practical method of hastening the union of a fracture, and a month or a year may pass before union is sound, but this period can be minimized by completely immobilizing the fragments and stimulating their blood supply by muscular contraction. Incomplete immobilization must retard union by shearing across the developing callus which bridges the gap between the fragments. Repeated shearing of the callus will lead eventually to sclerosis of the bone ends, which is the cause of established non-union, and the pseudarthroses which reside on the shelves of our pathological museums.

To immobilize a fracture of the shaft of a long bone it is necessary to fix the joints at each end of the bone in a degree of flexion sufficient to prevent rotation occurring between the fragments. Complete immobilization of a fracture can only be ensured by internal fixation with a bone graft or a plate, and it is probable that a plaster cast alone seldom effects complete immobilization because of the interposition of soft tissues between the plaster and the bone. Union of a fractured tibial shaft may be slightly delayed when treated in an above-knee walking plaster; nevertheless if the patient walks properly, rocking from the

by muscles: the bones form only a frame, and our object is to restore function.

To adapt a leg plaster for walking purposes our practice is to use a wooden heel, which is laced on to the plaster by means of a canvas "spat," and a toe-cap (Fig. 2). The heel is hollowed out on its upper surface, to which is glued a layer of half-inch sorbo rubber. The heel and toe-cap are standardized so that they may be used on almost any plaster. They enable a patient in a below-knee plaster to walk so naturally that a casual observer would not notice

FIG. 3.—Activity!

FIG. 2.—Walking-heel and toe-cap used to adapt a leg plaster for walking purposes. This heel affords sufficient stability for the patient to be able to balance on his injured limb, and encourages heel-toe movement.

heel on to the forefoot and pushing off with his toes, there will be a minimal amount of muscular wasting and stiffness when the plaster is discarded. This is because venous drainage from the dependent limb is maintained by intermittent muscular contraction, and static congestion, which causes partial anoxaemia, rapid muscular wasting, and adhesion formation, is prevented. In the treatment of any fracture just as much attention should be paid to the soft tissues as to the fracture. For movement is effected

anything wrong with him; and if the heel of an above-knee plaster is raised with a three-quarter-inch plaster slab before applying the walking-heel, and the heel of the shoe on the sound leg is raised with a three-quarter-inch wooden block, the patient is able to walk without sticks or crutches with an almost natural gait (Fig. 3). Unlike the walking-iron, the wooden heel affords sufficient stability for the patient to be able to balance on his injured limb. This stability gives him confidence and encourages him to rock forwards on to the toes instead of pivoting his foot outwards on the stud of the iron as he steps forwards. Attention to the detailed construction of a walking plaster is well repaid, because if a patient actively contracts the flexor muscles of his toes while walking and is able to walk without limping muscular wasting and stiffness are minimal when the plaster is discarded and function is rapidly regained. Several weeks of incapacitation of a patient who is being treated in an above-knee walking plaster may be prevented by mobilizing the knee-joint two weeks before discarding the plaster. This is not done by replacing the above-knee by a below-knee plaster, but by reinforcing the anterior part and cutting away the posterior part of the above-knee portion of the plaster so that the patient is able to sit and swing his leg, thereby regaining flexion movement. For walking, the plaster is bound to the thigh with a crêpe bandage. So long as the knee-joint is splinted in the flexed position no rotation can occur at the fracture. After discarding the plaster full movement of the knee-joint is regained by non-weight-bearing exercises, flexion and extension, rowing and bicycling, until the strength and tone of the quadriceps muscle are regained. Full movement of the tarsal joints and ankle-joints is usually regained within a week as the result of walking and remedial exercises, and the patient is not discharged until his calf muscles are

powerful enough for him to be able to raise himself on to his forefoot without assistance.

After discarding a walking plaster the extremity of the limb will become swollen during the daytime unless the soft tissues are supported by an elastic or some other kind of bandage, and this tendency to swell will persist until sufficient tone is regained in the calf muscles to maintain the venous circulation of the limb. This is explained to the patients, and they are instructed to avoid standing and always to elevate the limb when sitting so that it drains by the action of gravity. Congestion is the prelude to adhesion formation, and while it persists muscular tone will not be regained. This is but one reason why it is important to maintain the tone of the calf muscles throughout any period of necessary immobilization.

Compression fracture of one or more vertebral bodies, as the result of hyperflexion of the spine, is a common injury among air crews who have crashed. Many of these cases are unassociated with injury to the spinal cord, and the patient is able to walk away from the site of the crash, although he complains of a constant aching pain in his back. Cases that require transportation should be rolled on to a stretcher and carried flat, because hyperextension of an injured cervical spine may cause dislocation, and hyperflexion of the lumbar spine may increase the compression. Compression fractures can usually be decompressed by the pull of the anterior longitudinal ligament which occurs with hyperextension of the spine by the two-table technique. Comminuted fractures can usually be realigned very satisfactorily by this method, but they unite slowly and extension should be maintained for at least five months in a Watson-Jones plaster jacket. Neurological examination often reveals symptoms referable to root compression in cases of compression fracture of the spine. These symptoms are relieved by extension of the spine but will recur if immobilization is discontinued too early. Premature mobilization of a fractured vertebral body may be followed by progressive wedging and absorption of bone. No harm is done by unnecessary immobilization of the spine provided that the tone of the musculature is maintained, but premature mobilization may produce chronic symptoms.

Activity is an essential part of the treatment of these patients throughout the period of immobilization. Extension exercises are performed daily and a progress chart is kept of the weight which each patient is able to raise over a pulley by extending his spine. If the fracture is firmly consolidated and the power and tone of the back muscles are maintained, these patients are able to return to flying two weeks after discarding their spinal jackets.

Manipulation

Manipulation is of value for increasing the range of a stiff joint that has become stationary and for relieving the symptoms in a joint that gives rise to pain at one extreme of its range of movement.

Manipulation of a stiff joint is indicated only when the surgeon is satisfied that as the result of his own unaided activities the patient is unable to gain any increase in the range of movement of the joint and that the joint has not been subjected to any form of passive stretching. The manipulation should be performed under full surgical anaesthesia, so that the muscles are completely relaxed and the surgeon is able to feel the resistance which he has to overcome. The operation should not be performed until the adhesions have become crisp and avascular so that they snap easily and are followed by a minimal amount of reaction, and manipulation should therefore not be repeated at intervals of less than two months. No matter how great the discomfort the patient should begin active

unaided movements of the joint as soon as he has recovered sufficiently from the anaesthetic, and should repeat these movements at hourly intervals. He should retain 75% of the increase gained under anaesthesia and recover the remainder subsequently.

Flexion of the knee-joint may be limited by adhesions between the patella and the femur, in which case manipulation of the joint will very probably fracture the patella; the latter should be mobilized before manipulation is attempted. Before manipulation a stiff joint should be radiographed to exclude bony block. Every effort is made to obtain at least 90 degrees of flexion of the knee-joint, and radio-ulnar movement is absolutely essential for the management of an aircraft.

Manipulation of a joint in order to relieve pain at one extreme of its range of movement should not be attempted unless the manipulator has an intimate knowledge of the normal movements, both voluntary and involuntary, of the affected and neighbouring joints. Adhesions resulting from prolonged stasis are usually broken down by the patient's own activities, but occasionally pain may persist which can be localized to one joint and one particular movement. Focal infection, if present, should be eradicated before manipulation is attempted.

Derangement of Joints

The stability of any joint is dependent upon two factors—the shape of the articular surfaces and the strength and tone of the muscles which activate the joint. Dislocation of the shoulder-joint is a not uncommon injury among air crews. This joint depends almost entirely for its stability upon the strength and tone of the muscles which surround it, and unless the tone of these muscles is fully restored dislocation is liable to recur. A surprisingly large proportion of these injuries are associated with nerve lesions, due presumably to the violence of the dislocating force. The knee-joint is sometimes dislocated. One patient who ruptured the internal lateral ligament and both cruciate ligaments regained 100 degrees of flexion movement and the joint was completely stable unless he was caught off his guard, so that he was able to run and to play games, and this was because he regained excellent tone and great power of the quadriceps femoris muscle. Rupture of the external lateral ligament is sometimes associated with injury to the common peroneal nerve.

Decrease in the range of movement of a joint by shortening of muscles or their tendons may arise from prolonged

FIG. 4.—Extension splint to overcome contracture of flexor tendons.

splinting. This may result in flexion of the fingers when the wrist-joint is extended. The wrist must be stabilized by a plaster splint, and the fingers can then be slowly extended by the pull of elastic which is stretched between a wire frame and stalls worn on the fingers (Fig. 4). The

patient is encouraged to flex the fingers at frequent intervals against the pull of the elastic, and as he relaxes the flexor tendons are stretched.

The After-treatment of Burnt Hands

The rehabilitation of patients with burnt hands requires much patience and perseverance. Provided that the tendons and joints of the fingers have not been destroyed, the degree of recovery that is possible may exceed all expectation. The first thing is to assure the patient of this, and the second is to see that he works away at his stiff joints all day long. Whatever the initial treatment has been after burning, the skin is usually very thin and tender and sweats profusely. The stiffness is due to general adhesion formation around the tendons and joints of the fingers, and is caused by the initial reactionary oedema. The fingers are usually straight as the result of splinting. Movement is regained by immersing the hand in olive oil or in paste made with fuller's earth, which is heated to a temperature of 110° F. for two sessions of fifteen minutes daily. The patient is encouraged to squeeze a piece of rubber sponge or a ball while his hand is being heated. For the rest of the day he wears a detachable splint which dorsiflexes his wrist, and a glove to the finger-tips of which are attached lengths of elastic that are tied around a hook in the splint (Fig. 5). The constant pull of the elastic tends

FIG. 5.—Flexion splint to overcome stiffness after burning.

to flex the fingers, and the patient is encouraged at all times to oppose this by extending them. Treatment may take many weeks, but to regain the use of a hand justifies any amount of trouble.

Summary and Conclusions

In this paper the principles underlying the rehabilitation of injured air crews are described. Orthopaedic casualties are transferred to a rehabilitation centre after having received necessary surgical treatment in an orthopaedic hospital. Some of these would probably work out their own salvation without further supervision, but others would certainly prolong their incapacity unnecessarily. These casualties are therefore kept under almost constant supervision in order to restore maximal function and make as many as possible fit for further flying duties, and also to curtail incapacity.

Each patient is studied individually, for with his co-operation graduated remedial activity will restore function more rapidly than any form of passive treatment. Muscular wasting and stiffness, associated with immobilization, are prevented to a great extent by active contraction. A fracture is no reason for neglect of the soft tissues.

The criteria by which successful rehabilitation is judged are: first, the category of the patient on returning to duty; and, secondly, the time that he takes to regain function. Figures are as yet inconclusive, but 16% more patients were discharged to flying duties during the first six months that this department was working than during the six months before it opened.

TREATMENT OF HAEMORRHAGIC DISEASE OF THE NEWBORN*

BY

A. I. S. MACPHERSON, M.B., Ch.B., F.R.C.S.E.
Clinical Tutor, Royal Infirmary, Edinburgh; Crichton Research Scholar

The recognition of extreme prothrombin deficiency as by far the most frequent cause of spontaneous haemorrhage in the newborn and the discovery that vitamin K is essential for the maintenance of the normal plasma prothrombin level have raised to the status of a specific deficiency disease what had perforce been accepted as a mishap which "occurs without apparent reason" (Tallerman, 1937). Previously the only positive findings had been the report of Whipple (1913) that he had seen no prothrombin in a specimen of blood obtained after death from a fatal case of neonatal haemorrhage, and the observation that the clotting time tended to be prolonged for the first five days of life, returning to normal about the tenth day (Rodda, 1920). The treatment of haemorrhagic disease was correspondingly vague, the earlier clinicians advising local application of styptics, and, in the case of bleeding from the cord, even encircling the umbilicus with a deep suture. Injections of gelatin solution and of whole blood intramuscularly were introduced about the same time. This latter measure, despite the early recognition that spontaneous recovery from the haemorrhagic state occurred often enough to make its therapeutic value doubtful (Schloss and Commiskey, 1911, 1912), is still widely used as a routine treatment.

In the severer cases there has been general agreement that blood transfusion is a more efficacious procedure. The introduction of vitamin K, and more especially of vitamin K analogues, into clinical practice, and the demonstration of the rapid elevation of the prothrombin index which follows the administration of these substances to the newborn (Macpherson *et al.*, 1940), suggested another and apparently specific line of treatment for haemorrhagic disease, the successful use of which has already been reported in Europe and America (Nygaard, 1939; Waddell and Guerry, 1939; and others).

Since profound hypoprothrombinaemia is now recognized as the characteristic abnormality of the blood in haemorrhagic disease of the newborn, it follows that the efficacy of any method of treatment can be measured by its capacity (1) to raise the prothrombin content of the plasma so rapidly that the haemorrhage stops in a short time; and (2) to maintain the prothrombin at so nearly a normal level that the haemorrhagic tendency does not recur.

This communication reports an attempt to evaluate by these standards the merits of intramuscular injection of whole blood, blood transfusion, and injection of vitamin K analogues as treatment for haemorrhagic disease of the newborn.

Method Used

All prothrombin estimations have been made upon capillary blood by a modification of the method evolved in this hospital (Innes and Davidson, 1941) and found to give results closely comparable to those obtained by methods requiring the use of venous blood (Quick *et al.*, 1935; Ziffren *et al.*, 1939). The test has been performed as originally described except that (1) the oxalated blood has always been diluted with four times its own volume of saline; (2) the solutions have been kept at a constant temperature; (3) the lecithin-venom solution described by Hobson and Wits (1940) has been preferred, as it was

* Part of the expenses of this investigation has been defrayed by a grant from the Earl of Moray Endowment.

found to give a more definite end-point for the lower values of prothrombin. All results have been expressed as the "prothrombin index" (Illingworth, 1939) and charted as percentages of normal.

The Investigation

Ten cases of true haemorrhagic disease of the newborn have been treated by injection of whole blood into the buttock, by blood transfusion, or by injection of vitamin K analogues. The results of each line of treatment are reported in the first three sections below. Two cases of icterus gravis (erythroblastosis foetalis) also developed spontaneous and persistent haemorrhages, the treatment of which is briefly recorded in the fourth section.

1. INTRAMUSCULAR INJECTION OF WHOLE BLOOD

Intramuscular injection of whole blood has been employed in three cases. The effect upon the prothrombin index and upon the haemorrhagic manifestations is shown in Figs. 1, 2, and 3.

Case 6531.—Primipara. Normal labour (duration 21 hours); spontaneous delivery. Birth weight, 6½ lb. Birth condition satisfactory. Haematemesis (red and altered blood) at 32 hours of age. 10 c.cm. whole blood into buttock. Clinical condition did not improve. Haematemesis continued till further treatment with vitamin K analogue was given twenty-five hours later.

Case 6780.—9-para. Prolonged inert labour (duration 60 hours). Spontaneous delivery. Birth weight, 5½ lb. Put to breast. Haematemesis at 24 hours of age, followed by melaena. 17 c.cm. whole blood into buttock at 32 hours. Bleeding continued with increasing pallor, so that transfusion was required at 38 hours.

Case 7252.—Primipara. Occipito-posterior position requiring manual rotation and later forceps, both under anaesthesia. 76½ hours' labour. Birth weight, 8½ lb. Glucose-saline followed by one feed of breast milk and water aa 1 oz. Haematemesis first occurred at 32 hours of age. Gastric lavage 10 hours later gave return of frank blood. 10 c.cm. whole citrated blood into buttock at 49 hours, 17 c.cm. at 52 hours, and 9 c.cm. at 55 hours. Four hours later haematemesis recurred, the clotting time was found

to have risen to 12 minutes, and the prothrombin index had fallen to a level lower than it had been before treatment. Bleeding had persisted from heel-stab throughout this time, but stopped two hours after the injection of vitamin K analogue intramuscularly (see below).

The elevation in the prothrombin index obtained by the intramuscular injection of whole blood has proved to be so slight and so transient that only in Case 6531 did it even temporarily affect the course of the haemorrhagic disease. Moreover, in Case 7252, in which repeated injections

were given, the temperature was raised to 101° F. or over during the ensuing thirty-six hours and both buttocks were tense and painful. The risk of this procedure in less favourable surroundings is obvious.

2. BLOOD TRANSFUSION

Two cases have been treated by whole fresh blood transfusion (Figs. 2 and 4).

Case 6780 (continued).—So much blood had been lost from the alimentary canal that haemoglobin was 40% at 38 hours. 90 c.cm. of whole blood transfused into superior sagittal sinus. Approximately an hour later haemoglobin was 55% and prothrombin index 66, and all superficial bleeding had stopped. The last vomit of altered blood appeared 90 minutes later, and melaena lasted till approximately 56 hours. Cyanosis and restlessness were pronounced after the transfusion, the latter being controlled only by repeated doses of chloral.

Case 6947.—Primipara. Assisted breech delivery after 36 hours' labour. Melaena appeared and oozing from abrasion on scrotum began at about 90 hours of age. Transfusion of 50 c.cm. whole blood into superior sagittal sinus at 96 hours. Bleeding stopped at end of transfusion, but recurred 5 hours later and persisted (soaking the dressings applied) for 12 hours till further treatment was given (see below).

Both cases were characterized by a rapid improvement in the prothrombin index and by the early cessation of bleeding. In both, however, subsequent readings showed an almost equally rapid fall in the prothrombin index. This fall was arrested in Case 6780, a level (about 50%)

FIG. 1.—Case 6531.

FIG. 2.—Case 6780.
Correction: 55 haemoglobin should be over 2½' and 66.

FIG. 3.—Case 7252.

FIG. 4.—Case 6947.

above the bleeding threshold persisting for about twenty hours before further, apparently spontaneous, elevation occurred. To this case a very large transfusion (approximately one-third of its own blood volume) had been given. In Case 6947, in which the estimated blood volume was about five times greater than the volume of blood transfused, the prothrombin index fell almost to its original level and bleeding recurred five hours after the transfusion had been given.

3. INJECTION OF VITAMIN K ANALOGUES

Vitamin K analogues have been given by injection to six cases (Figs. 1, 3, 4, and 5). Fig. 5 shows the effect obtained clinically and upon the prothrombin index by intramuscular injection of 2.5 mg. of 2-methyl-1:4-naphthoquinone in oil (B), and by intramuscular injection of 5 mg. (A) and the intravenous injection of 2.5 mg. of water-soluble 2-methyl-1:4-naphthohydroquinone disuccinate (C). In each instance bleeding was controlled within about two hours. The prothrombin index curves show a rapid and remarkably parallel rise to a high level, which was subsequently maintained throughout the whole of the neonatal period. So far as can be judged, intravenous injection does not produce better results than deep intramuscular. It is important to give the oily solution deeply, as too superficial an injection will promote irritative local lesions.

Case 5754.—Primipara. Easy 10-hour labour with spontaneous delivery of 4½-lb. child following medical induction for pre-eclamptic toxæmia. Clinical jaundice with pale faeces appeared on fourth day and steadily deepened. Bleeding from heel-stab persisted from 156 to 165½ hours. 5 mg. 2-methyl-1:4-naphthohydroquinone disuccinate given by intramuscular injection at 163 hours. Clotting activity remained at normal despite the following findings: Faecal fats—total, 33.7%; split, 29.7% of total. Icteric index, 33.3. Laevulose tolerance test: 30 min., 6 mg. per 100 c.cm.; 60 min., 6 mg.; and 120 min., 7 mg. Died at 264 hours, apparently from hepatic dysfunction.

Case 5551.—Classical Caesarean section of election for hypertension. Birth weight, 9½ lb. Birth condition satisfactory. Persistent ooze from heel-stab began at 29 hours. Intramuscular injection of 2.5 mg. 2-methyl-1:4-naphthoquinone at 31 hours led to cessation of bleeding two hours later.

Case 6765.—6 para. Normal labour (duration 11 hours). Spontaneous delivery. Birth weight, 5½ lb. Copious melaena first noticed at 54 hours of age. Intravenous injection 2-methyl-1:4-naphthohydroquinone disuccinate at 71 hours. No further fresh bleeding. Melaena persisted for further 20 hours, suggesting a bleeding-point high in the intestinal tract.

In three cases (Figs. 1, 3, and 4) vitamin K analogues were given after haemotherapy had failed to control haemorrhage or to raise and maintain the prothrombin

index. In each instance an immediate and lasting response was obtained both clinically and in the level of the prothrombin index—an effect too rapid to be influenced by any concomitant tendency to spontaneous recovery, and in

Table showing Prothrombin Index

Case No.	Before Vitamin K	After Vitamin K	
		Less than 12 hours	Less than 24 hours
6295	35	70	78
6633	24	—	85
6912	33	—	65

marked contrast to the results of the other methods tried. In three other cases which have been treated by injection of 2.5 mg. of 2-methyl-1:4-naphthoquinone the prothrombin index estimations have been made less frequently than in the cases already recorded. In each instance, however, frank bleeding stopped in a short time and the prothrombin index rose to and remained at normal or nearly normal levels (see Table).

4. ICTERUS GRAVIS

Two cases of icterus gravis showed spontaneous haemorrhages which were treated successfully by the intramuscular injection of 2.5 mg. of 2-methyl-1:4-naphthoquinone in oil. The prothrombin index and certain other details of Case 7152 are charted in Fig. 6.* From the therapeutic point of view the interesting feature is the rapid and sustained effect given by vitamin K analogue even when a laevulose-tolerance test indicated a considerable depression of liver function.

FIG. 5.—A=Case 5754. B=Case 5551. C=Case 6765. (For description see text.)

FIG. 6.—Case 7152. Broken line=bleeding time (B.T.). Continuous line=prothrombin index (P.I.).

Discussion

In spite of the proved effect of vitamin K in increasing the clotting activity of blood in such a way that spontaneous bleeding ceases in a very short time, it has been authoritatively stated that the administration of adult blood intravenously or by repeated intramuscular injections not only is a safer measure for general use but gives "results . . . among the most striking in therapeutics" (*Lancet*, 1940, 1941). Clearly the very small and fleeting response even to the repeated injection of adult blood into the buttocks can be instrumental in controlling the haemorrhagic tendency only when the prothrombin index is already rising spontaneously. Moreover, repeated injection of so much blood is not devoid of danger. Blood transfusion in the newborn is a procedure that can be undertaken only in hospital, and even there may be followed by untoward

* These cases will be recorded in more detail later by Dr. J. L. Henderson, to whom I am grateful for the reticulocyte and haemoglobin estimations.

reactions. The evidence from two cases treated by transfusion supports the observation that even when a comparatively large volume of blood is given to an adult the effect upon the clotting activity is transient (Stewart, 1939). It appears from Case 6947 that when a transfusion of average volume is given the immediate effect upon the prothrombin index is dramatic (more rapid, though more limited, than can be obtained from the injection of vitamin K analogue alone). Unless, however, this early rise is supported by concurrent spontaneous restoration the prothrombin may fall to its original level and bleeding recur in a very few hours.

The prompt and maintained increase in the plasma prothrombin and the rapid control of haemorrhage (within two hours of administration where bleeding was superficial) after the injection of vitamin K analogues are manifestly quite independent of any coexistent tendency to spontaneous recovery. Moreover, 2.5 mg. of 2-methyl-1:4-naphthoquinone intramuscularly restored the prothrombin index and maintained it at adult levels even when the laevulose-tolerance test indicated deficient hepatic function (Case 7152). The site of injection (intravenous or intramuscular) has no effect upon the rapidity of action, and there is no material difference between oil-soluble and water-soluble preparations. The simplicity of this method and the extreme rarity of conditions in which vitamin K analogues will not be effective in arresting the haemorrhagic tendency suggest that one of them should be employed first in all cases of spontaneous and persistent bleeding in the newborn. It is probable that in the most severe cases, in which prolonged or massive haemorrhage is exsanguinating the patient, simultaneous treatment by transfusion and injection of vitamin K analogue should be given. The rapid action of the transfusion in elevating the haemoglobin and plasma prothrombin levels would then be reinforced by the slightly slower and much more sustained effect of the vitamin K analogue on the clotting activity of the blood.

I am much indebted to Dr. E. McCallum, who has helped me with the prothrombin estimations in several of the cases described; and to Dr. J. L. Henderson for his interest in bringing some of these cases to my notice and for his assistance in other ways. Also I wish to thank Dr. W. F. T. Haultain, Dr. Douglas Miller, Prof. R. W. Johnstone, and Prof. Charles McNeil, who have given me every facility to carry out these investigations on the cases under their care. I am indebted to Glaxo Laboratories Ltd. and to Roche Products Limited for generous supplies of vitamin K analogues.

The borough of Chelmsford, with an estimated population of 33,040, reports twenty-eight deaths of children under 1 year during 1940, and only ten deaths among young persons between 1 and 25 years. An attempt was made to establish a day nursery for children between 2 and 5, but the scheme had to be abandoned, chiefly owing to the difficulty of bringing and collecting children in the black-out, and of obtaining money, staff, and accommodation. The M.O.H. notes a good response to the diphtheria immunization campaign, and only three cases were reported during the year, with no deaths.

THE CAUSES UNDERLYING THE RECENT INCREASED INCIDENCE OF AND MORTALITY FROM TUBERCULOSIS IN GLASGOW

BY

STUART LAIDLAW, B.Sc., M.D., D.P.H., D.P.A.

AND

DUNCAN MACFARLANE, M.B., Ch.B., D.P.H.

(From the Public Health Department, Glasgow)

Pulmonary Tuberculosis

It would appear that for five years preceding the outbreak of war in 1939 the incidence of and the mortality from pulmonary tuberculosis were tending to stabilize themselves in Glasgow at figures of around 1,650 notifications and 960 deaths per annum. During the first year of war the returns under the above two headings were 1,908 and 1,177 respectively, a rise of approximately 250 notifications and 200 deaths. This increased incidence and mortality is being maintained during 1941.

The following table shows the total number of notifications and deaths from pulmonary tuberculosis during the past seven years, together with a forecast for 1941 based on the returns for the first half of the year:

Year	Notifications	Deaths	Year	Notifications	Deaths
1934	1,646	873	1938	1,748	960
1935	1,757	972	1939	1,574	972
1936	1,647	979	1940	1,908	1,177
1937	1,654	955	1941*	2,190	1,342

* Estimated figure—i.e., twice the notifications and deaths during the first half of 1941.

The seasonal incidence of notifications from pulmonary tuberculosis for the years 1939, 1940, and 1941 was studied when it was found that the graphs for 1940 and 1941 followed closely the path of the graph for 1939, but at a slightly higher level. It was observed that the rise in notifications during 1940 and 1941 was normally distributed throughout the year, and did not occur in any one particular season.

The age and sex distribution of the notified cases of pulmonary tuberculosis for 1939 and 1940 are tabulated below:

Age	Males		Females	
	1939	1940	1939	1940
— 5 years	34	47	21	40
— 15 "	68	45	50	71
— 25 "	237	287	341	437
— 35 "	162	218	162	214
— 45 "	130	164	72	82
— 55 "	119	127	42	27
— 65 "	79	79	25	26
— 65 "	23	31	9	13
Total	852	998	722	910

The total number of notifications was 1,574 in 1939 and 1,908 in 1940. During the first half of 1941 there were 1,095 notifications and 671 deaths—figures that indicate that the disease is continuing to increase in incidence.

It will be seen from the table that the increased incidence has taken place almost entirely between the ages of 15 and 45 in males and 15 and 35 in females, and that both sexes show an all-round increase of 20% over the 1939 returns.

Non-pulmonary Tuberculosis

The comparative figures for non-pulmonary tuberculosis for 1939 and 1940 also show that a considerable rise in the number of notifications and deaths from this form of tuber-

culosis had occurred in the latter year. The relative figures were: 561 notifications and 255 deaths for 1939, and 669 notifications and 329 deaths for 1940. It will be seen that the increase, approximately 17%, in this group is slightly lower than among the pulmonary cases.

The following table subdivides the notified cases of non-pulmonary tuberculosis into their particular types.

Year	Abdomen	Spine	Hip	Other Bones and Joints	Genito-urinary	Skin	Lymph Glands	Meninges	Multiple
1939	82	39	39	88	29	21	90	137	2
1940	80	60	37	101	38	18	130	184	4

From this it is seen that the spine, the meninges, and the lymph glands have shown the greatest increase in tuberculosis, while other sites have remained relatively unaffected. It was considered worth while to extract the age and sex distribution of the meningeal cases in order to discover which age groups were chiefly affected. It was found that the increase occurred in children of both sexes under 5 years, and to a lesser extent in females aged 15 to 25.

Possible Reasons for the Increased Incidence

It is evident from the above details that there must have been some factor in 1940 which was not present in 1939, or, if present, was intensified in 1940. The possible reasons for this increase are considered under separate headings.

(a) *Increased Virulence of the Tubercle Bacillus.*—The figures show that the notifications and deaths during 1940 increased in equal ratio, but there is no proof that the bacillus has become more virulent.

(b) *Malnutrition and Deficient Diet.*—This is not an important factor in the increased incidence of tuberculosis, for the following reasons: (1) The State has controlled the distribution of essential foods in such a way that each individual obtains a fixed minimum quantity of basic foodstuffs sufficient in itself to maintain the normal person in good health. (2) It can be presumed that if deficiency of diet was the main factor the various age groups would be affected equally when expressed on a percentage basis, whereas from the tables it has been seen that the maximum rise occurred in the 15-45 age group. This group comprises the workers, many fewer of whom were unemployed, and who on account of higher wages were able to feed themselves well.

(c) *Tubercle Bacilli in Milk.*—This may be considered a factor in producing some of the additional cases of tuberculosis affecting the lymph glands, but the fact that the number of cases of abdominal tuberculosis has remained stationary indicates that it cannot be the main reason for the increased incidence among non-pulmonary cases.

(d) *Examination by Military Medical Boards.*—These examinations have undoubtedly revealed some unsuspected cases of tuberculosis in the age group 20-35, but the number of cases so notified is not nearly comparable to the actual increase.

(e) *Exertion or Strain of Army Life.*—That the unaccustomed rigours of Army life have not been a dominant factor in the increase among males during 1940 is shown by the fact that the number of civil notifications in that year exceeded the total returns for 1939.

(f) *Long Hours in Shelters.*—This may cause a slight increase in the number of registered cases, but it is obviously of minor importance. Raids in Glasgow have been so infrequent that shelters have not been occupied to any considerable extent, and only a very small percentage of the population frequent them when there is no warning.

(g) *Overcrowding in Factories.*—Were contact infection in factories an important feature, one would have anticipated a proportionately greater percentage increase among pulmonary as compared with non-pulmonary tuberculosis—in fact, the increase is roughly 20% in each case.

(h) *Long Hours, Overwork, Strain, and Curtailed Rest.*—It has been noted that the main increase involved the age groups 15-45 in males and 15-35 in females. This is the period of

maximum working activity, when long hours of overtime are often undertaken. It must also be remembered that many a period normally devoted to rest or recreation has now to be sacrificed to fire-watching or Home Guard duties. In addition to this we have ascertained that young adults of both sexes are frequenting dance halls and picture houses with great regularity, and in numbers as high as, if not higher than, before the outbreak of hostilities. The significance of the rise in the 15-45 group in males becomes even more apparent when one realizes that the number of civilian males in this age group in 1940 has been considerably depleted by the calls of military service.

In the case of females the institution of marriage and the ties of family life necessitate a shorter working life among large numbers. This would account for the drop in female notifications at an earlier period than with males—a fact that is confirmed by the following tables of occupations:

	1939	1940
Pre-school children and scholars	173	165
Military class	35	71
Professional class	35	30
Commercial class	218	211
Domestic class	309	321
Miscellaneous	121	208
Tradesmen		
Unskilled workers	674	932
Skilled workers		
Labourers		

Our conclusion, therefore, is that it is a combination of long hours, overtime, strain, and ill-spent leisure which is the factor producing the rise in the number of cases of tuberculosis, and it may be assumed that the increase will be at least maintained so long as these factors remain unchanged.

AVOIDABLE DISABILITY SEEN IN RECENT AMPUTATIONS

BY

W. R. D. MITCHELL, M.Ch.(Orth.), F.R.C.S.Ed.
Orthopaedic Surgeon, Emergency Medical Service;
late Ministry of Pensions

Since the present war began many publications have appeared on the subject of amputation. The multiplicity of advice given renders difficult the choice of procedure for those with little or no experience upon which to draw. It is not the object of this paper to criticize individual methods of amputation, but simply to draw attention to certain types of case in which different operative technique and after-care would have resulted in speedier recovery with less disability. At the present stage it is impossible to evaluate some of the newer methods, but it is not too early to point out that procedures are still being employed which have already been condemned by examination of the results of the amputations performed in the last war. All the patients forming the basis of these observations have been seen in one of the special hospitals after primary amputation in Army or Emergency Medical Service units.

As amputation below the knee presents the greatest number of difficulties and comprises a large proportion of all amputations, the causes of prolonged disability will be

PROLONGED DISABILITY IN AMPUTATIONS BELOW THE KNEE

- | Cause | Effect |
|--|---|
| 1. Bad design of skin flaps..... | (a) Healing by secondary intention with or without terminal low-grade osteitis.
(b) Painful scar.
(c) Intertrigo from loose folds.
(d) Late breakdown. |
| 2. Skin grafting of bare areas.... | Stump will not stand artificial limb. |
| 3. Too early re-amputation..... | Post-operative sepsis. |
| 4. Failure to use skin traction in guillotine amputations | (a) Pain and misery.
(b) Loss of length at re-amputation. |
| 5. Failure to use post-operative splintage (applies especially to knee)..... | Flexion deformity. |

considered in detail in relation to this stump. The various headings will also be found to cover, to some extent, disability in relation to other amputation stumps.

Skin Flaps

No blame can be attached to the surgeon when the injury does not permit of planned flaps, but numbers of almost identical stumps have been seen where the design leaves no doubt that they have been planned as such. An example is the use of equal lateral flaps, giving an antero-posterior scar. This fashion has been recommended in a recent publication on war surgery because of the better drainage afforded. Good drainage is unquestionably advisable, but methods must surely be employed which do not cause additional disability. The objection raised to equal lateral flaps in amputation below the knee is the occurrence of a scar on the subcutaneous part of the tibia. In the post-operative period failure to heal by first intention exposes the tibia and adds many additional weeks to hospital treatment. Should the scar heal by first intention it is still placed at the point of maximum pressure between the end of the tibia and the socket of the prosthesis when the leg is swung forward in walking. Late breakdown may occur, especially if the scar is adherent to the bone.

It is not with these late complications that we are most concerned, but with those stumps that have not yet healed and show a small area of apparently dead bone projecting from the end. Radiographs of these stumps may eventually show terminal sequestration, but only after many months of waiting. Re-amputation below the knee while the wound is still open is impossible without risk, as the majority only measure six to seven inches below the knee. When the wound has healed or almost healed with a thin covering of scar tissue, re-amputation, with removal of one inch or more of bone, may enable the surgeon to cover the stump with sound skin flaps. To allow a patient to be fitted with his prosthesis when the stump end is covered only by scar tissue is to lay the foundations of trouble and disappointment. Therefore re-amputation, though wasteful of time, is necessary in order to provide a serviceable stump. It is hoped that the practice of using equal lateral flaps for amputations below the knee will rapidly disappear.

Another type of flap, the long anterior, which has been the standard textbook recommendation for many years, is still seen in recent amputations. Fortunately its use appears to be on the wane, for it has proved to be one of the least desirable flaps on account of its poor blood supply. Necrosis of the skin at the distal part of the flap may be a post-operative complication, but is not nearly so serious as necrosis of the skin overlying the tibia. The problem presented by ulceration of part of the flap over the tibia is exactly similar to that described in connexion with the antero-posterior scar. As Verrall has stated, the ideal scar, from the point of view of both skin nourishment and limb-fitting, is secured by the use of short anterior and long posterior flaps.

A number of stumps are still found with too generous a skin covering, and require the removal of superfluous skin before the artificial limb can be worn in comfort. This is a minor operation and adds little to the total disability period, but it deserves mention because some patients, already fitted with limbs, have had troublesome intertrigo from infolding of the skin or friction in the socket. Skin flaps should be tailored neatly on the stump at the time of amputation. If this is done there will be fewer possible sites for haematoma formation with the attendant risk of sepsis, and the time necessary for shrinking the stump will be lessened. The ideal stump is, of course, firm and tapering to the end, with rounded contours and a minimum of flabby tissue.

Skin Grafting

Although skin-grafting has been performed on a few occasions the results have been unsatisfactory. Re-amputation, as soon as sepsis will allow, has been the only method of securing a serviceable stump. Various types of free graft and the tube pedicle graft, transferred in two stages from the abdomen, have been done. The Thiersch graft is not strong enough to stand the wear of the socket, and the whole-thickness grafts encountered so far have been so irregular with scars in vulnerable positions that limb-fitting was out of the question. Patients who have undergone several operations for grafting, with a long pre- or post-operative period of stump dressing, are naturally disappointed when informed that re-amputation is necessary.

Guillotine Amputations without Skin Traction

Too many cases of this type have been seen; the patient's misery is so real and so unnecessary. In the rush and hurry inseparable from this form of amputation time is really saved by taking a few seconds longer to cut through the skin at a lower level than the other structures. Two or three sutures can then be inserted over a generous gauze pack. This method is quicker than the application of skin traction with a weight over the end of the bed, and is effective for all but the very rare case in which it is desired to keep open the whole area of cross-section for drainage purposes. Skin traction has been applied at a late stage with little success. Three to four inches have often been lost at re-amputation in the thigh, while the loss in the lower leg has usually been less.

Too Early Re-amputation

Patients who have already undergone re-amputation have been received with discharging amputation stumps. It does not seem to be fully appreciated that re-amputation of two to three inches of a stump which is septic or has been septic is a procedure fraught with considerable danger of post-operative sepsis. With a clear five inches or more the risk is less. Stumps should be healed, or almost healed, before re-amputation is performed, and it is advisable to allow the patient to be up and about before the operation in order to activate latent sepsis, which otherwise might make its appearance at the time of operation or later. Ideally, before operating on the patient in whom every inch is of importance, the surgeon should wait for healing by scar tissue and a period of massage and heat to test for latent sepsis, but in view of the time involved operation may sometimes be considered a justifiable risk when the bare area appears really clean without a trace of surrounding oedema or tenderness. After all, re-amputation is a plastic operation done at leisure, and the result is usually of much greater importance than the excision of a facial scar, which has so much time and care lavished on its performance by plastic surgeons.

Flexion Deformity at Knee or Hip

This is one of the most easily avoided disabilities connected with amputations in the lower extremity, yet it is surprising how often it is encountered when the patient is sent for limb-fitting. Knee-joints are safe from this deformity if bandaged to a back splint for the healing period, but in amputations above the knee the hip-joint must be inspected to see that extension remains full. Ward routine should preclude the possibility of the stump resting on a pillow. Flexion deformity of either hip or knee is a serious disability, and its complete correction is an extremely difficult problem. In fact, if the deformity has lasted for more than a few weeks it is unlikely that it can be entirely cured.

A CASE OF UNILATERAL CLUBBING OF THE FINGERS

WITH A SUMMARY OF THE LITERATURE

BY

R. EWING RODGERS, M.D., M.R.C.P.

Medical First Assistant, Sheffield Royal Infirmary

The first observer to describe this rare condition was Ogle in 1859. Others to describe and collect cases were Bécclère (1901), Castex and Mazzei (1939), Groedel (1907), Hatzieganu (1923), Högler (1920), Loucaides (1932), Mendlowitz (1938), Pigney (1920), Souques (1919), and Walsh and Alldredge (1934). A case observed recently is now described.

Case History

A male quarry worker aged 54 was admitted complaining of pain in the right arm and a lump on the right side of the neck for six months. At first the lump was not painful, but it gradually increased in size and pain occurred, first in the right upper arm

FIG. 1.

FIG. 2.

and later in the forearm. The patient also noticed a change in the shape of his fingers. There was no cough or dyspnoea, and no history of syphilis was admitted.

On examination a pulsatile swelling, $2\frac{1}{2}$ by $2\frac{1}{2}$ inches, was seen just above the right clavicle; a systolic thrill and murmur were present over the swelling. There was pitting oedema and venous engorgement of the right upper limb. The right hand was constantly warmer than the left. There was pronounced finger clubbing of the right hand and curvature of the nails; the left hand was normal (Fig. 1). The power in the right upper limb was poor compared with the left (the patient was right-handed). The sensation and reflexes were normal in both arms, and the circumference of the arms 3 inches above the elbow was: right $8\frac{1}{2}$ inches,

left 9 inches (measured after oedema had subsided with rest and one month's treatment). The pulse at the right wrist was less forceful than that at the left. Blood-pressure readings were: right arm 118/84, left arm 124/88. The heart showed no enlargement clinically, but there was a systolic murmur over the aortic area. The pupils reacted to light and accommodation; the knee-jerks were present. No tracheal tug was observed. The sedimentation rate (Cutler) was 25 mm. in one hour, and the Wassermann reaction was strongly positive. Radiographs showed: (1) extensive soft-tissue shadow above the right clavicle, but nothing abnormal in the chest; (2) slight decalcification of both hands, right greater than left; (3) slight decalcification of bones of right forearm.

The case was diagnosed as syphilitic aortitis, with right subclavian aneurysm and secondary unilateral clubbing of the fingers of the right hand; and rest, potassium iodide, and mercury were prescribed. Later bismostab 0.2 gramme was given weekly. The aneurysm gradually decreased to about three-quarters of its original size, and the oedema and much of the pain and venous dilatation disappeared.

The patient, when seen six months later, had voluntarily discontinued treatment for three months; his aneurysm was much larger, and the clubbing more pronounced (Fig. 2). He has recently been operated on successfully, the aneurysm having been tied off both distally and proximally. It is too early to assess any change in the clubbing, but all his symptoms have disappeared.

Discussion

Clubbing of the fingers occurs bilaterally in various conditions, chiefly in cardiac and pulmonary disease. Other

Cases reported in the Literature

Reporter	Observer	Accompanying Lesion

states, such as cirrhosis of the liver, ulcerative colitis, sprue, amoebic dysentery, and post-thyroidectomy myxoedema, occasionally present clubbing (Mendlowitz, 1938). It therefore seems difficult to deduce a single cause, and circulatory, chemical, and nervous factors may all play a part.

Of the 29 cases of unilateral clubbing of the fingers reported in the literature, 24 occurred with aneurysms, chiefly of the subclavian arteries (see Table). In the remaining 5 pressure was observed on the vessels and nerves of the affected limb. This pressure seems to be the only factor common to all the 29 cases, but it is not clear whether it was on the arteries, veins, nerves, or lymphatics, or on a

combination of these, as the clinical signs accompanying the clubbing varied considerably. In the case reported above there was, clinically, obstruction of the vessels as shown by oedema, venous dilatation, pulse, and blood pressure. Subsequently, pressure on the nerves gave rise to pain.

Ogle (1859) thought that the clubbing was due to the presence of an increased amount of venous blood in the affected limb and that this was caused by interference with the axillary circulation. Other observers thought it was due to interference with the sympathetic nerves running with the vessels, but as it is now known that sympathetic nerve fibres do not run down the whole length of the arteries this theory seems untenable.

Mendlowitz (1938) investigated the circulation in the arms of 4 cases of unilateral clubbing and found no evidence of a circulatory cause. He compared the maximum heat elimination and blood pressure gradient from brachial to digital areas in both the normal and affected arms and found that no significant changes in the blood flow had occurred in the affected finger-tips. However, only 4 cases were investigated, and the results of the experiments were not very conclusive. Local anoxaemia due to circulatory embarrassment still remains a very probable cause of clubbing.

Chemical causes, such as toxæmia, seem very probable when bilateral cases are considered. Thus, bronchiectasis, a disease with general toxæmia, is commonly accompanied by bilateral clubbing. However, if general toxæmia were always the cause, unilateral clubbing should never occur. There remains the possibility that the localized pressure, for instance from an aneurysm, might precipitate incipient clubbing on one side, and that the other side might eventually show clubbing if the patient lived long enough. It is interesting to note that cases of an aneurysm causing pressure and pronounced clubbing in one hand have sometimes shown slight clubbing of the other hand (Béclère, 1901; Hatzieganu, 1923). It seems unlikely that pressure on the nerves of the arm could be the cause of clubbing, as although nervous symptoms are common in unilateral cases they do not occur in bilateral cases.

Finally, it may be noted that in 2 of the reported cases the clubbing disappeared wholly or partially after operation on the aneurysm (Hatzieganu, 1923; Höglér, 1920). This is convincing evidence that pressure is the primary factor in unilateral cases. Local circulatory embarrassment follows this pressure, causing anoxaemia and, hence, probably the clubbing. Anoxaemia from circulatory embarrassment or general toxæmia in bilateral cases may well account for the clubbing, so conforming with the final factor in unilateral cases.

Summary

A case of unilateral clubbing of the fingers is described.

The cases previously reported are tabulated.

The difficulty of explaining the exact causation is stressed and the possibilities are discussed.

I wish to thank Prof. E. J. Wayne for permission to publish this case, and Dr. L. C. D. Hermitte for the photographs.

Medical Memoranda

Cirrhosis of Liver and Perforated Gastric Ulcer in an Infant of 6 Months

The only type of infantile cirrhosis which I can trace in medical literature is one which occurs in India. It was first described by Twining in 1832, and its morbid anatomy was investigated by Gibbons in 1891. A full account of this disease is given by Sir Upendranath Brahmachari and Phanindranath Brahmachari in volume 8 of the *British Encyclopaedia of Medical Practice*. I can find no record of a similar condition in this country, nor of any case in which the terminal event was a perforated gastric ulcer, though Brahmachari refers to gastric and intestinal haemorrhage as a common complication. A non syphilitic cirrhosis, originating as an intralobular and progressing to a multilobular cirrhosis, occurring in an infant of this age and terminating in a perforated pyloric ulcer at 6 months must be very uncommon in this country; and if the brother's liver was also cirrhotic the condition must be, as in the Indian case familial. Two other children appear to be healthy.

CASE RECORD

A male child aged 5½ months was sent to me by Dr. Bruce of Newport. The history was that he weighed 9 lb. at birth, and that, beyond a somewhat intense icterus which persisted for some days, the puerperium was normal. It was found, however, that the infant did not thrive on the breast. Dried milk preparations did not result in improvement, and on these stools were fatty in appearance. On sweetened condensed milk he thrived for a time, but on resuming dried milk he lost weight. It was found that the liver was very large, extending to the umbilicus. No free fluid was detected in the abdomen and there was no enlargement of the spleen. There had been no jaundice since the neo-natal period. A former child of the same family had also had a much enlarged liver, and had died of pneumonia at 2 years of age. A provisional diagnosis of von Gierke's (glycogen) disease was made.

The blood sugar was first investigated. The fasting blood sugar was 100 mg. per 100 c.cm.; one hour after a feed of 5 c. of sterilized milk it was 225 mg., and after two hours 160 mg. The effect of adrenaline was observed, for in von Gierke's disease this drug does not raise the blood sugar. On this occasion the fasting blood sugar was 140 mg.; 5 oz. of adrenaline 1 in 1,0 raised this to 160 mg. The urine contained glucose and acetone. The blood count was: red cells, 3,700,000 per c.mm.; haemoglobin, 80%; white cells, 12,400 per c.mm. (polymorphs 29 lymphocytes 70%, large mononuclears 1%). The Wassermann reaction was negative. I concluded that this was not a case of von Gierke's disease, but a true diabetes mellitus with hepatic megaly, and decided to try the effect of 3 units of soluble insulin twice a day. On the second day the infant suddenly collapsed and died at 11.15 a.m.—four hours after his third dose of insulin. Just before death he passed a quantity of blood per rectum. No time did he seem to have any pain.

Post-mortem Examination.—The abdomen contained about 8 to 10 oz. of cloudy fluid. The liver had the typical appearance of multilobular cirrhosis. On raising the liver I discovered the cause of the cloudiness of the fluid in the abdomen, a perforated ulcer of the pylorus on the greater curvature exuding partially digested milk, and this, mingling with straw-coloured ascitic fluid, produced the turbid appearance. The small and large intestines were full of blood. The spleen was normal in size. The liver weighed 22 oz. The pathological report on the liver was as follows: "Sections show considerable cirrhosis; this is to some extent of multilobular type, numerous delicate fibrous bands are seen surrounding most of the individual lobules, and conforming more to a billobular (Hanot's) cirrhosis, though there is no evidence of active duct regeneration."

My thanks are due to Dr. Bruce for his account of the history of this case, and to Dr. Douglas Thornton for his report on sections of the liver, as also to his staff for pathological investigation.

Reviews

THE SCIENTIFIC ATTITUDE TO LIFE

The Scientific Attitude. By C. H. Waddington. Pelican Books. (Pp. 126. 6d.) Middlesex: Penguin Books, Ltd.

In 1932 an eminent man of science wrote: "Not meddling with morals and politics; such I would urge is the normal condition of tolerance and immunity for scientific pursuits in a civilized State. . . . Science should remain aloof and detached, not from any sense of superiority, not from any indifference to the common welfare, but as a condition of complete intellectual honesty." We do not give the writer's name as he has doubtless changed his mind, since the events of subsequent years have proved the inadequacy of such a point of view. Science can no longer remain aloof, impartially dispensing material comfort with one hand and methods of destruction with the other. A scientific training should imply a scientific attitude to life. All too obviously this has rarely been the case in the past, and a scientist's opinion on matters outside his subject has often been not worth much more than that of a film star on politics.

The younger generation of scientific workers, to their honour be it said, are intensely interested in the impact of science on the outside world, and Dr. C. H. Waddington, himself a researcher of repute, has attempted to define his views on what the scientific attitude to life should be. He tells us that his little book originated from discussions at the club which produced the Penguin Special *Science in War*. It reads like a rough draft of his ideas, but he modestly states that a number of his friends laughed him out of the "more excruciating absurdities" of that draft. It is to be wished that those friends could have helped him in other ways, for there is a lack of lucidity and a disregard of the niceties of the English language which hamper the effectiveness of this obviously sincere work. This is not surprising, as much of the author's thought seems to be still in a state of fermentation. Penetrating beneath the froth of this ferment we read his main thesis to be a rejection of the plea that science is and must be ethically neutral. He maintains that a scientific attitude to the world does not in the slightest deny the emotional effects produced on men by their experience: what it tries to do is to classify the mechanisms by which these effects were produced. Man is the only animal to discover the secret of getting results in the material world, which is to let one's actions be governed by an objective analysis of the situation. Our task is to enable this analysis to get results when applied to politics. The author is critical of both Fascism and Communism, though he clearly inclines to the left. He realizes that his plea for the application of conscious control to the economic functioning of society, which he regards as a step forward in evolutionary progress, will meet with opposition, for with Wilfred Trotter he recognizes that people object strongly and irrationally to anything which touches a part of their personality that is out of order. Science can satisfy the other side of man's nature which demands a belief in some authority, a thrill of romance. Science can not only satisfy reason, but he believes it could also provide this thrill and this authority: it is able to provide mankind with a way of life which is, in the first place, self-consistent and harmonious; and, secondly, free for the exercise of that objective reason on which our material progress depends. It is all to the good that many of our younger men of science are devoting so much thought and energy to the difficult problems that lie ahead, but they will do well to remember that authorship, like the laboratory, has its special technique.

HISTOLOGY FOR MEDICAL STUDENTS

Textbook of Histology for Medical Students. By Evelyn E. Hewer, D.Sc. Second edition. (Pp. 364: illustrated, 17s. 6d. net.) London: William Heinemann (Medical Books) Ltd. 1941.

The writing of textbooks for medical students on special subjects has become, with the advance of knowledge, an increasingly difficult task, since the time allotted for the study of such subjects in the already overburdened curriculum is very short. Dr. Evelyn E. Hewer has overcome this difficulty with much success, and has contrived to accentuate those points which are essential; and, also realizing the desirability of giving some indication of the meaning of the various morphological features which are described, she has introduced supplementary notes of practical importance, bearing upon the relation of certain changed appearances in cell structure to phases in the life-history of the cell, functional activity, certain diseased conditions, and changes due to the mode of fixation or staining of the tissue. A considerable number of new and excellent photomicrographs have been added to those of the preceding edition, and also some new schematic drawings. The latter, however, in our opinion are capable of improvement in their technique, this being scratchy and of a blackboard type. One would like to have found in this book a more adequate description of the central nervous system and also of histogenesis, the latter of which may be regarded as having the same fundamental relation to histology and general pathology that general embryology has to anatomy and surgical pathology. The general neglect of this study has hitherto led to the perpetuation of certain initial errors, and more particularly with regard to the structure of some of the connective tissues. This is obviously due to the failure of many writers to appreciate the full meaning of some well-established facts—such as the formation in the early stages of implantation of the ovum, of continuous multinuclear plasmodial strands, and the primary continuity of mesenchymal tissue in the embryo—upon the formation of corresponding structures in the adult body—for instance, chorion epithelioma and many forms of connective tissue. The book, however, is well written and contains much new and interesting matter, and it will well serve its purpose—namely, an introduction to the study of histology for medical students.

CARLOS FINLAY AND YELLOW FEVER

Carlos Finlay and Yellow Fever. By Carlos E. Finlay, M.D., F.A.C.S., Professor of Ophthalmology, University of Havana. Edited by Morton C. Kahn, M.A., Ph.D., Sc.D. (Pp. 249. 21s. net.) Published under the auspices of the Institute of Tropical Medicine of the University of Havana by the Oxford University Press, New York.

So far back as 1881, long before anything was known of the insect transmission of disease, Carlos Finlay put forward his hypothesis of the transmission of yellow fever by the mosquito, based on what was known of the epidemiology and pathology of the disease. In later years he added more and more cogency to the reasoning by which this view was upheld. He even selected as the vector the species of mosquito that we now know does convey the disease. At a time when practically nothing was known of mosquitoes in the Tropics Finlay bred and studied *Aedes aegypti*, at that time the *Culex* mosquito. He also carried out feeding experiments, using this mosquito, with the view of transmitting the mild disease and so bringing about protective immunity to the person bitten. In regard to such experiments one can only say that at the time they did not carry complete conviction, so that it was nearly twenty years later before the results of the U.S. Army Yellow Fever Commission showed with certainty that yellow fever was conveyed by the mosquito and not by aerial contamination or fomites. Nevertheless Finlay in 1893, long before the first operations

were undertaken against yellow fever by the destruction of mosquitoes, advocated such measures, along with protection from bites of infected mosquitoes as the essential action necessary in the prevention of yellow fever.

These remarkable facts have recently been vividly brought to the reader's attention in a book by his son, Carlos E. Finlay, giving an account of Finlay's family and personal life and the researches which led to his mosquito theory. This is told not as a formal history but in the intimate detail of an observer behind the scenes. Incidentally the book gives an informative picture of the whole progress of research on yellow fever from the early observations to the more recent discoveries, together with what is known as a result of historical research of the origin of this once dreaded disease. It is well documented, and authentic dates and references are given throughout. It forms an important contribution to the history of our knowledge of tropical diseases.

Notes on Books

Your Health in Wartime: A Doctor Talks to You, by Dr. CHARLES HILL, is published at 1s. by the University of London Press. This little book is a revised version of a series of broadcasts given last January, with the addition of a section on food. In simple yet attractive style suitable for children of school age Dr. Hill deals with such topics as the way germs spread and how the body defends itself against them, touching lightly on the

methods adopted to strengthen those defences. Then the bearing of cleanliness on health is discussed, together with the importance of ventilation, rest, and sleep. In the final chapter on food emphasis is laid on the importance of proteins as body-builders, which, as is well known, cannot be replaced by any other food-stuff. "If there is a shortage of one body-builder we must rely on another." Years ago Sir Robert Hutchison said that in order to have enough protein it was necessary to take too much. This paradox implies that in the breaking down of food proteins it is best for the body to have a wide choice in order to select the most appropriate building material. He regarded this as a means of increasing resistance against disease. Unfortunately it is just the proteins which are being most severely rationed. This may be inevitable, but scarcely justifies the self-commendation to which the Ministry of Food is rather prone. It is well that everyone should know the important facts so engagingly set forth in this book.

Medical officers of the South African Army Medical Corps now on active service, when writing home, have often expressed their wish for medical literature, especially such publications as may be applicable to field conditions in Africa. Some of them have access to the *Bulletin of War Medicine*, published in England by the Medical Research Council, but for those not so favourably placed the South African Red Cross Society has entrusted to a subcommittee the task of providing an abstract service especially designed for S.A.A.M.C. officers. Copies have reached this country of Nos. 1 and 2 of the *Digest of War Medicine*, published by the South African Red Cross Society, P.O. Box 8726, Johannesburg, Transvaal, South Africa.

Preparations and Appliances

EXTENSION FOOT-PIECE AND SUPPORT FOR USE WITH THE THOMAS LEG-SPLINT

Colonel E. A. McCUSKER, M.C., A.D.M.S. of a Canadian Division, writes:

For some time it has been evident to me that a simpler method of applying the Thomas splint must be devised in order to obtain the maximum benefit from its use, in addition to which the procedure is wasteful of time and material. The difficulties encountered in the ordinary method of application are numerous: (a) Many bandages are required to make a trough in which to support the fractured leg. (These need adjusting, which is difficult in the dark, and they require so much handling that cleanliness is impossible.) (b) The clove-hitch presents difficulties to the inexperienced. (c) The calliper is not satisfactory, nor is the skewer. (d) A short piece of wood or metal must be carried for a windlass to obtain traction. (e) The reversible stirrup (Sinclair) must be carried, it is not steady, and a bandage must be used to anchor the foot to it. (f) Suspension cannot be obtained until the patient is placed on the stretcher. The suspension bar is then put in position and bandages must be used to suspend and anchor the splint. (g) The patient cannot be removed from the stretcher without removing the suspension bar.

To simplify this technique it is suggested that a stockinet be slipped over the Thomas splint to form the supporting trough. This can be sterilized and carried in a waterproof case attached to the splint. It requires little handling and can be put on in the dark.

It can be washed several times and decontaminated if exposed to gas. It is inexpensive. (If surgical stockinet is not available the leg of an old pair of under-pants serves admirably.)

The combined extension foot-piece, which can now be slipped on, takes the place of all other equipment in that: (1) The spring instep clamp is attached to the waist of the boot and

passes through the oval hole in the centre of the foot-plate. The toe is fixed to prevent lateral rotation. (2) Extension is obtained and maintained by a rope or strap from the spring instep clamp to the notch in the end of the splint. (3) From the heel of the foot-piece a bar of light iron extends downwards two inches, then bends at right-angles towards the body to rest on the ground or on the stretcher and takes the place of the suspension bar. (4) The patient can be moved readily to and from the stretcher. (5) The toe-piece extends high enough to carry the weight of blankets.

(6) The foot-piece is attached to a cross-bar by a hinge: this bar is turned at each end to fold around the parallel bars of the splint, on which it can slide to the desired position, but which prevents any lateral or rotary movement. When not in use the foot-piece folds through 90 degrees to lie parallel to the bars of the splint. It is tied in this position, and cannot be lost.

The advantages of the method are, first, its simplicity, economy, lightness, and mobility; secondly, that highly trained personnel are not required for rapid and satisfactory application.

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY SEPTEMBER 27 1941

SHELTERS AND THE COMING WINTER

War has brought in its train two interrelated social revolutions. One is evacuation; the other, the crowding of urban populations into shelters. The first thing that comes home to a visitor to an air-raid shelter in London or any large town is the necessity for evacuation of every child up to school-leaving age and of elderly and infirm persons. If this were complete many shelter problems would no longer arise. The fact has to be faced, however, that the habitual shelter population does include a large proportion of children as well as other persons for whom life in even the best-conditioned shelter is detrimental.

Improvement has undoubtedly taken place during the past twelve months of trial and experiment. This is borne out by an investigation recently undertaken on behalf of this *Journal* of shelters in many London boroughs and in seven principal cities of Great Britain, some of the results of which are summarized in this and last week's issues. Some shelters now come up to a standard with which only the most fastidious could find fault, but many others fall far below that level. One important fact, nevertheless, is that in well-arranged dormitory shelters the conditions of health and amenity are better than many of the very poor, who are the most regular of the shelterers, experience in their own homes. The authorities in different areas, even in adjacent boroughs, have approached this new problem in very diverse ways. Some seem almost to resent the fact that it is their duty to provide this accommodation, and they carry out only the niggardly minimum required; others deal with the problem imaginatively and on bold lines. Some have appointed a special official to look after the shelters; others have attempted no kind of co-ordination between the four or five different departments concerned in construction, equipment, and maintenance, thus causing long delays in getting work done, with a result less satisfactory than it might have been. The Ministry of Health has recently issued a pamphlet entitled *Air-raid Shelters: Notes on Principal Provisions*; this contains some excellent advice which, if followed in the spirit as well as in the strict letter, would ensure good shelters all over the country and eliminate the anomalies that at present exist.

The service of the medical aid post shows striking variations in different places. Sometimes so great an emphasis is laid upon the emergency character of this provision that the posts are hardly used at all. But where those responsible are alive to the necessity and opportunity for preventive measures the posts are in constant requisition, much timely advice is given, and many patients are referred to their own doctor or to a hospital. In some shelter communities it has been

possible to introduce diphtheria immunization on a large scale or to practise the systematic spraying of children's throats. How valuable an aid-post service may be is illustrated from the experience of a large shelter in a provincial town where, owing to its reconstruction from a disused canal, the floor was constantly damp and the walls reeking; yet there was very little illness last winter among the thousands of people it accommodated, thanks to the work and vigilance of the doctors and nurses attached to the post. The treatment of the child problem in the shelters is very unequal. In many places the children seem to be ignored. In others they are watched carefully in order that advantage may be taken of any apparent deviation from health to insist upon evacuation. One obvious omission is the complete lack of provision for nursing mothers to tend their infants in privacy. Only in the model medical aid post now being constructed at Newcastle, apparently, has any thought been given to this matter. Another point noted was the absence of inspection lamps or torches for the service of the medical aid posts, and of surgical material for dealing with cuts and lacerations.

The original timber-and-canvas bunks, which were easily damaged, becoming filthy from use and harbouring any parasite which might find its way into the shelter, are gradually being replaced by all-steel bunks, larger, of better construction, and more restful for the sleeper. There is now usually more space between bunks, and sometimes a plywood screen is placed at the bunk head to prevent droplet infection. Some shelters are bunked to capacity, with no room to move about. Most authorities discourage sleeping in shelters in the absence of an "alert." One city is proposing to remove every night ten thousand of its in-town population to special shelters on the periphery of the city.

The provision for cleansing is one of the most unsatisfactory features in many areas. Sometimes everything is left to the shelterers themselves or the responsibility is placed upon the shelter wardens; sometimes there are occasional visits from the cleansing departments. In a few instances shelters are provided with both water-closets and chemical closets, the latter remaining closed unless a breakdown in the water supply or drainage occurs. The provision of drinking-water is most primitive in some places. In one large city cans were found provided in most of the shelters; elsewhere, stone jars or a sealed container. But in the great majority of shelters a tap is taken from the main. Lighting is another difficulty. Some authorities have installed an alternative source should the main system be put out of action. One city has an emergency battery set in every shelter, but in another the only emergency lighting in most of the shelters is naked candles. Hurricane lamps or oil lamps are often provided, but in places there is no emergency lighting at all. Sometimes provision is made for dimming the lights at a certain hour to permit of the people getting better sleep, but elsewhere, notably in the London tube stations, the lights glare brilliantly all the night long. In one big city, after complaint had been made that the bright lights prevented sleep, the authorities substituted lights so feeble that it is impossible for people to read or usefully to occupy themselves in the evening. For heating the shelters the Ministry of Health recom-

mends Cura stoves, but if these are to function properly they must be put in by an expert. A most successful heating installation was seen at Liverpool in the shape of a concrete box or cover containing a heating element. Another good type of heater was a thermostatically controlled heating bar seen in several places. In no case was gas-heating seen, and the few oil stoves are gradually being replaced by electrical appliances. Some officials argued that so long as the shelter is dry the people will keep themselves warm, but in some basement shelters the draughts in cold weather must create an arctic-like atmosphere.

The actual construction of shelters is not primarily a medical problem, but from all aspects of health, physical and psychological, the narrow trench shelters and adapted tunnels and tube station platforms are not satisfactory, because in these passages there is not enough room for movement. The best kind of shelters are those which can be bayed off into approximately square compartments, with a section for medical aid post, canteen, and recreative facilities. The keystone of shelter life is the warden. If there is a good warden there is a good shelter. Women wardens, especially the motherly type not younger than 40, are in most instances more suitable than men. In its recent memorandum the Ministry of Health has recommended the employment of women wardens in the proportion of one to four or five men. It would be advantageous if the proportion in the large shelters—that is, those holding 500 and over—were at least one woman to two men and in smaller shelters one woman to one man. Two large provincial authorities prefer women wardens to men as they find they are more conscientious and have a better influence in the shelters.

No doubt shelters will be developed and improved still further. The shelter problem is by no means solved. Perhaps when the solution is reached and the perfect shelter makes its appearance the need for it will have passed away.

COLLAPSE THERAPY IN PULMONARY TUBERCULOSIS

The benefit that individual patients derive from collapse therapy is now generally admitted. The opposition by some workers to its wider application therefore needs examination. It is sometimes maintained that the proportion of cases suitable for this treatment is very small, because usually either the disease will heal with a sanatorium regime or rest in bed, or it is already too advanced. In this view the time factor is considered of little importance, and the fact that indications for collapse vary with the experience and skill of the treating team of physician and surgeon is ignored. Sometimes, also, published results are quoted to show the slight benefit gained by large groups of patients from individual collapse methods. We have already pointed out¹ that the results can be truly assessed only when collapse therapy is regarded as a whole, for the decision to use it implies that "the least serious method

applicable to the particular case will then be chosen, to be followed by others the choice of which will depend on the effect obtained by the first." Other workers appear to regard collapse therapy as a substitute for rest in bed, and not as an ancillary method which, if good results are to ensue, must be supported by complete rest until quiescence is established. Others, again, stress—perhaps overstress—the difficulties and potential complications, which, in fact, largely depend on proper choice of method and conduct of treatment. They tend to consider the more drastic methods of collapse to be almost reckless, and their caution is supported by the belief that "chronics," if left alone, carry on for years a comfortable though restricted life. But this expectation is not supported by vital statistics, and pays scant regard to the personal factor—that is, the various circumstances on which the patient's life will depend.

Up to the present collapse therapy on a scale that might be expected to influence fatality rates in whole communities has been practised in very few centres. It is not surprising, therefore, that Drolet in his statistical studies² found that "surgical treatment," and incidentally "sanatorium treatment" too, has so far had little effect upon these rates. (A source of error may have been introduced by Drolet in his calculations, as suggested by Bogen³ and recently emphasized by Potter.⁴) We have already drawn attention⁵ to results of widely applied collapse therapy, and this must be taken to mean its use at an early stage of treatment. Results recently given by Potter⁶ deserve publicity. A follow-up study was made of two groups of patients: the first, treated in sanatorium between 1926 and 1932, consisted of 1,458 patients, of whom 6.2% received collapse therapy; the second, treated between 1932 and 1938, consisted of 1,619 patients, of whom 61.2% "were subjected to one or a combination of the procedures of pneumothorax, phrenic interruption, and thoracoplasty." The radiographs taken of all patients on their admission were reviewed, and the present criteria of the American National Tuberculosis Association were used in classifying the stage of the disease. In each case the course of the disease was followed by serial films and/or clinical observations. The groups were found to be comparable with one another in age and in extent of tuberculosis. "Far advanced disease" existed in 88% of each group.

From the period between 1932 and 1938 only 19 patients could not be traced. In this group there were 151 patients in whom disease was controlled by rest alone. For 276 the outlook was considered hopeless from the beginning, and the remaining 992 were considered suitable for collapse therapy. In 378 (38%) of these the collapse was effective: at the end of the six-year period 323 were working or ambulant, and 13 (3.4%) had died. In 553 pneumothorax was abandoned and other forms of collapse proved ineffective: 81 of these were working or ambulant (in 49 the cavity closed spontaneously), and 240 had died. In 61 the collapse was effective on one side but there was a cavity in the contralateral lung; 30 were working or ambulant and

4 had died. (Potter also gives figures to show the good remote, as well as immediate, results of effectively collapsed cases.) When the 1,458 patients treated in 1926-32 were classified according to the stage of tuberculosis and indications for collapse therapy (by the same standards as the more recent group, 109 being untraced), it was found that collapse therapy should have been attempted in 801. According to the follow-up findings in the 1932-8 group effective collapse might have been anticipated in 38%—that is, in 305 patients; only 3.4% of these (that is, 10 patients) should have been dead at the end of the six-year period in 1932. Actually 222 had died by then. Comparing the whole of each group of patients, Potter found that at the end of the six-year period 1926-32 1,026 of the 1,458 traced patients (that is, 76%) had died; 109 were untraced, and it may reasonably be expected that a large proportion of these died too. At the end of the six-year period 1932-8 only 708 (or 44% of the 1,619 patients) had died (19 patients being untraced).

These figures appear to be the most convincing yet brought forward to prove the value of collapse therapy. But we agree with Potter when he says: "We do not mean to imply . . . that the results in effective collapse therapy are entirely responsible for the difference in the total death rates in the two periods, for more energetic application of bed-rest, and the clinical improvement in the ineffectively collapsed cases which not infrequently followed, served to prolong life in the patients treated in later years."

INEFFICIENT STEAM STERILIZATION

Puerperal tetanus, of which a case was recorded in this *Journal* last month by MacLean and Challen,¹ is an exceedingly rare disease, and when it occurs its origin may be in doubt. Nevertheless the fact that Pulvertaft² was able to attribute a case of tetanus after hysterectomy to infection from an unsterilized vulval pad led, by way of a request from the Medical Officer of Health for the County of London, to the appointment by the Royal College of Obstetricians and Gynaecologists of a committee to investigate the possible transmission of anaerobic infections by surgical dressings, with special reference to vulval pads as a source of tetanus. This committee has now issued its report.³ Two of its nine members were bacteriologists, Dr. G. W. Goodhart and Prof. J. McIntosh, and they undertook an investigation of the properties of cotton-wool which took them into factories as well as laboratories, the results of which make it perfectly clear why this material invariably contains spore-bearing bacteria. Brown cotton-wool undergoes no chemical treatment, and therefore contains bacteria from the soil in which it was grown. White cotton-wool is bleached by boiling in alkali and subsequent treatment with chlorine, and this process sterilizes it, but after washing in water—a treatment which at the factory investigated loaded it with cocci owing to the multiplication of these organisms in a softening plant—it is dried in a current of hot air. The blower fans in the premises examined were close to the floor in such a situation as to suck up dust from crude cotton-wool and even street dirt; cotton-wool is, of course, an excellent filter for particulate matter in air, and the large volume of air necessarily employed served therefore

to recontaminate the material thoroughly. Sporogenous bacteria were in fact cultivated from all samples examined: these included *Cl. welchii* in several cases and proved *Cl. tetani* in one. To filter the air used for drying or to sterilize the material in bulk in the factory may or may not be practicable, but unless and until such a precaution is taken, cotton-wool requires efficient steam sterilization before use for surgical purposes. The committee then inquired into the efficiency of this process as carried out in various hospitals. Their general conclusion is that although the autoclaves were generally of satisfactory design certain features of their use were open to criticism. In some cases those responsible for packing material in drums were unaware that overnight packing can prevent adequate penetration by steam. Sterilization was not always carried out under rigidly controlled conditions of time and temperature; and sometimes, when such conditions were observed and the apparatus furnished automatically a graphic record of working, it was no one's business to inspect this and to reject any batch of dressings for which the record was unsatisfactory. Periodic tests were not always made, and when made consisted in some cases of observing colour changes in capsules, a method of test which is considered unreliable. The report therefore makes detailed recommendations about the manner of using autoclaves, the main points in which are loose packing of drums, evacuation to a negative pressure of 20 to 25 inches of mercury, the maintenance of a steam pressure of 20 pounds for 20 minutes, and a monthly bacteriological test with spore-bearing anaerobes. If steam sterilization is so often imperfect, it may well be asked why accidents consequent on it are so rare. The probable answer is that previous washing frees such articles as towels of most of their bacteria, and cotton-wool, though in a class apart owing to the regularity with which it is contaminated with resistant bacteria, is not ordinarily used in such a way that infection from it is likely to occur.

HEALTH IN THE SOVIET UNION

The Society for Cultural Relations with the Soviet Union arranged in London a largely attended week-end school for teachers, when various aspects of Soviet life were demonstrated. One session was devoted to health and medical services. Dr. Joan McMichael, who travelled extensively in Russia shortly before the war, described the preventive aspect from which the Soviet Government approaches these problems. Free medical treatment is the right of every Soviet citizen according to Article 120 of the Constitution, and the surveillance of the Government extends from a little before the cradle (ante-natal services) to a little beyond the grave (the storage of healthy cadaver blood in the institute at Moscow). Dr. McMichael paid special attention to the school health services, where a great deal seems to be done by the children themselves. In the upper classes of Soviet schools the children elect their own health inspectors, one of whose duties is to keep a daily diary, noting all absences, with a view to the early discovery of infectious illness. The children also elect five or six of their health inspectors to attend the municipal schools health assembly. During an anti-malarial campaign throughout the Soviet Union the children were encouraged to work in their own laboratories on the problem of the malarial parasite, and at an all-Union conference on malaria in Moscow these children sent along their own representative, who contributed some original work on the subject which was highly acclaimed. Dr. McMichael praised the ingenuity of the Russians in

² *Ibid.*, 1937, 1, 441.

³ *J. Obstet. Gynaecol. Brit. Emp.*, 1941, 48, 394.

giving health subjects a popular appeal. The museums in Russia, including the health museum with its models and films of health and sanitation services, are crowded at every hour of the day. The nearest equivalent to the Soviet polyclinic is one of our large health centres with some introductions from the out-patient department of a voluntary hospital, but it is quite separate from the hospital, and, although there are beds for examination purposes, there are no in-patients. A dietetic restaurant is attached to all these polyclinics. Consulting-rooms and equipment are, of course, provided by the State, but the patient can see his or her own doctor and can be referred by him to a specialist in the building. If the patient's doctor has reason to believe that the working or housing conditions of the patient are deleterious to health he has the right to make personal investigations and to recommend changes to the management. Soviet hospitals, Dr. McMichael said, did not greatly differ from hospitals elsewhere, but one unusual feature was the monthly or fortnightly conferences of the whole hospital, including the staff from consultants to ward-maids, and the patients. The ambulance service in Moscow is so organized that if an accident occurs anywhere in the city the victim is brought to the central hospital within eight minutes, where a surgical team awaits him and blood transfusion is given if necessary. She spoke of many other features of Soviet life, such as the dairy kitchens and breast-milk stations attached to the maternity and child welfare centres, and the statement of protein, carbohydrate, and fat values given on the menus in the State restaurants.

COMPULSORY PASTEURIZATION IN ONTARIO

In 1938 the Province of Ontario, convinced that further progress in rendering the milk supply safe needed something more than voluntary effort, decided upon compulsory legislation. An amendment to the Public Health Act was therefore introduced making pasteurization compulsory in all cities and towns irrespective of the size of the population. Provision was also made for applying the Act by Order in Council to any other area recommended by the Minister of Health. The purpose of this clause was, of course, to bring in at a later date rural areas, pleasure resorts, and other places that were likely to present special difficulties at the start. One important feature of the Act is the requirement that all milk must be pasteurized in plants that have been approved by the Provincial Department of Health, and that a yearly certificate of approval must be obtained for each plant to show that it is still conforming to the official demands. Anyone familiar with the lack of uniformity of control in Great Britain, where pasteurizing plants are licensed by local authorities often having little or no knowledge of the important factors concerned, will appreciate the wisdom of this enactment. Though this legislation has been in operation for only two years, considerable progress has been made. According to Dr. A. E. Berry,¹ Director of the Division of Sanitary Engineering in the Ontario Department of Health, 27 cities and 147 towns came automatically under the Act. Seven different Orders in Council have since been passed designating villages, townships, and rural areas. All villages and police villages of 500 inhabitants or over have been brought under the Act, and many smaller communities are likewise included. It is estimated that over 98% of all milk now sold in Ontario for consumption in the fluid state is pasteurized. To do this 813 licensed plants are necessary

—a figure probably more than double that for the rest of the Dominion. Difficulties have been encountered, as was to be expected, but on the whole progress has been remarkably rapid and opposition has not been serious. By exonerating local authorities from the necessity of deciding for or against pasteurization—a decision that had formerly to be taken by bodies largely untrained in public health methods—and by insisting on uniform requirements for all pasteurizing plants in the Province, it has removed two important obstacles to a progressive programme of milk control. The difficulty of providing sparsely populated rural areas with adequately pasteurized milk is proving by no means insuperable. Plants have been established at convenient centres from which milk can be delivered over relatively wide areas. It is as yet too early to say what the effect on the eradication of milk-borne diseases is likely to be, but it is interesting to note that the typhoid fever death rate in 1939 was halved, that cases of undulant fever were reduced by about 45%, and that a substantial diminution was apparent in the infantile mortality rate. Ontario is to be congratulated on being the first large area in the British Empire to introduce compulsory pasteurization. It is to be hoped that others will soon follow its example.

INTRAPERITONEAL SULPHANILAMIDE

It was only after four years of its systemic use that sulphanilamide began to be tried extensively as a local application. No one regarded it as an antiseptic in the ordinary sense until the work of Fildes and his collaborators explained the mechanism of its action; for the mystification which preceded this we have chiefly to thank those German and French authors who maintained that its action on bacteria was indirect and in some unspecified way required the co-operation of the body as a whole. For a year or more now sulphanilamide powder has been proving its worth as an application to infected wounds, whether as a prophylactic or for the treatment of chronic infections, particularly streptococcal. No doubt other uses of this kind will be found; dermatology appears to afford an extensive scope for trials of the method, and possibilities of successful local application of sulphathiazole in the upper air passages are envisaged by M. E. Delafield and Edith Straker¹ in a recent issue of this *Journal*. Now a further new use for sulphanilamide has been found by S. Rosenberg and N. M. Wall,² who advocate its local use 'in peritonitis—an interesting suggestion, because, although these authors do not refer to it, some of the earliest experimental work on sulphonamide compounds has a bearing on this method of treatment. The peritoneum was the battleground of a controversy between Levaditi on the one hand, who maintained that local introduction of the drug in streptococcal peritonitis in mice was ineffective, and argued hence that sulphanilamide had to undergo some change elsewhere in the body before it could act, and Colebrook on the other, who found that intraperitoneal injection of the drug was effective. We now know, of course, that there is no *a priori* reason why sulphanilamide should not act locally in peritonitis provided that the bacteria concerned are susceptible to it, that adequate distribution can be achieved, and that the drug persists *in situ* long enough to secure a useful effect. Rosenberg and Wall first tested the method in rats, giving them an intraperitoneal injection of cultures containing coliform bacilli and various nondescript cocci made from cases of suppurative appendicitis or peritonitis.

¹ *British Medical Journal*, 1941, 2, 221.
² *Surg. Gynec. Obstet.*, 1941, 72, 568.

¹ *Canad. publ. Hlth. J.*, 1941, 32, 208.

and treating them by intraperitoneal injection of sulphanilamide suspended in saline. This treatment saved about half the animals if applied immediately, and some even if delayed; it appeared to be more effective than subcutaneous injection of the drug. It has since been tried in ten patients with peritonitis, mostly of appendicular origin, with encouraging results, quantities of from 1 to 4 grammes of sulphanilamide powder being "placed" in the peritoneal cavity at the end of the operation: this treatment was usually followed by systemic administration, the subcutaneous route being chosen. Although a few observations were made on blood sulphanilamide levels after this initial procedure, it is clearly desirable to know more about the rate of absorption from the inflamed peritoneum, and to discover if possible what degree of diffusion takes place in the peritoneal cavity itself: it is a little difficult to picture the dispersion of such comparatively small doses throughout the area affected in a widespread peritonitis. Further observations should also take account of the nature of the infection, including anaerobes: these were apparently eliminated from the inoculum in these authors' animal experiments by the method of cultivation employed, and they are disregarded in the clinical reports. It is by no means certain which of the very various bacteria escaping from a perforation in the lower part of the alimentary tract are chiefly responsible for the damage which ensues, and their susceptibility to sulphanilamide varies greatly, *Streptococcus faecalis*, for instance, being completely resistant to it. Such studies might even throw some light on the alleged complicity of *Cl. welchii* toxæmia in producing the graver manifestations of peritonitis.

PASSING OF ANTI-PNEUMOCOCCAL SERUM

We have discussed on several previous occasions the possible future of serum treatment in pneumonia. So far as we are aware, in this country it is dead or at least moribund, but its progress here has always lagged far behind that in the United States, and general adoption of the method would have been a slow process even in the absence of competition by chemotherapy. In America serum treatment and all the diagnostic facilities which it demands have in many centres been organized to perfection, and produced solid and striking results on a scale unapproached elsewhere. It is from there that the final judgment on the future place of serum in treatment must come. Since the first somewhat sceptical reception of sulphapyridine in America opinion has slowly veered towards increasing emphasis on the value of chemotherapy and less on that of serum. Alternation of the two treatments for the sake of comparison ceased some time ago, and nearly all patients receive chemotherapy. But the list of alleged indications for giving serum in addition or even, exceptionally, alone has remained considerable: these, as reviewed in our columns a year ago, were said to include hepatic and renal disease, disorders of the blood-forming organs, extensive consolidation, profuse bacteraemia, advanced age, and pregnancy. Combined treatment also had the sanction of well-attested experimental support: mice, in this as in other infections, respond better to serum plus drug than to either alone. Although this position might well have been sustained indefinitely, a further stage in the displacement of serum treatment to a minor role seems to have been reached in the studies of N. Plummer and his colleagues¹ at the Bellevue Hospital, New York. In all their 607 cases chemotherapy was begun as soon as specimens of blood and sputum had been obtained: the type of pneumococcus was determined, and as soon as this

information was available alternate cases of each type were also given concentrated rabbit anti-pneumococcal serum. The two series are therefore as strictly comparable as the design of this study could make them; and an analysis of their clinical features also shows uniformity between them. When a case due for serum treatment had already responded to chemotherapy when a type diagnosis was forthcoming serum was not given, but the case remains for the purpose of assessment in the drug-plus-serum group, a policy which tends perhaps to flatter this treatment: to remove the case from this group would of course unduly weight the scales in favour of chemotherapy alone. Among 306 patients treated by chemotherapy alone there were 34 deaths, a mortality of 11.1%: of 301 patients receiving drug and serum 44 died, or 14.6%. The exclusion of deaths within twenty-four hours of starting treatment reduces these mortality rates to 9.3 and 9.8% respectively. The trivial difference between these figures persists throughout a closer analysis: there is no greater difference whether the cases were treated early or late, whether they were in the higher or lower age groups, and whether or not they had bacteraemia—a feature the incidence of which in this series was 20.6%. Composite temperature records of the Type I and Type II cases show an almost identical rate of fall in both forms of treatment. There is no important difference in the frequency of various complications: 10 patients diagnosed as having pneumococcal endocarditis and 7 complicated by pneumococcal meningitis all died whether serum had been given or not. The drugs used were sulphapyridine in three forms, sulphathiazole, sulphamethylthiazole, and sulphadiazine, and there is little to choose between them, but the three last named were used in too few of the cases for any exact conclusions to be drawn about their relative merits. It should be added in explanation of the fairly high gross mortality that all cases of pneumococcal pneumonia were included, regardless of their distribution or origin; in a large proportion of the fatal cases pneumonia was a complication of some other serious disease.

The authors' final conclusion is inevitably that serum need be given only to those patients who cannot tolerate sulphonamide treatment, or who do not respond adequately to it within twenty-four or forty-eight hours. This second indication is open to argument, and the first, strictly interpreted as meaning patients who have previously had severe toxic reactions, is a rarity. It has to be remembered that the production of concentrated serum for treating the many different types of pneumococcal infection is a laborious and costly process, and increasing restriction of indications for its use may reduce demand to an uneconomic supply level. Will anti-pneumococcal serum, though a far more potent therapeutic agent, go the same way as anti-meningococcal?

The Czechoslovak Executive Committee of the recent meeting of Czechoslovak-Polish doctors has sent the following message to the British Medical Association: "The members present at the meeting of Czechoslovak-Polish doctors, held in Edinburgh on September 11 and 12, unanimously decided to send their best greetings to their colleagues in the British Commonwealth of Nations. The present period, in which the fate of humanity is being decided, emphasizes the exceptional importance of the close co-operation of all democratic medical science, as well as the early reparation of the severe deterioration in health caused by the war let loose against democratic forces, and also for closer medical co-operation in all its spheres after the war. The Czechoslovak and Polish doctors are looking forward with all their hearts to this collaboration with the British medical world."

¹ *J. Amer. med. Ass.*, 1941, 116, 2366.

A PROCEDURE FOR THE TREATMENT OF GAS CASUALTIES

BY

L. A. STOCKEN, B.Sc., A.I.C.

AND

R. H. S. THOMPSON, M.A., B.Sc., B.M., B.Ch.

(Department of Biochemistry, Oxford)

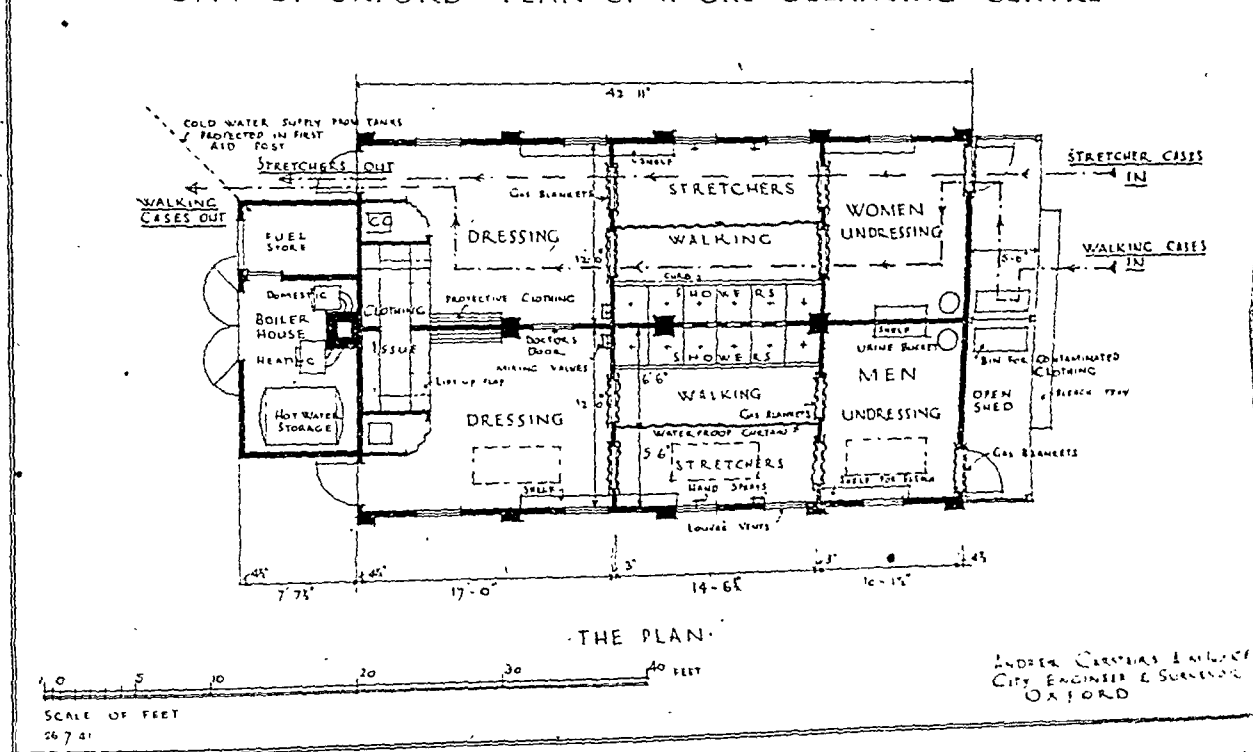

The cleansing of gas casualties presents two major problems: first, the treatment of the gas burns on the body surface; secondly, the marking, cleansing, and returning to the rightful owners of all gas-contaminated clothing. From the nature of the physical and pathological processes underlying vesication by blister gases it is at once obvious that excessive elaboration of the second of these two

divided into male and female sides, each side consisting of a stripping-shed, an undressing-room, a shower-room, and a dressing-room, with a common equipment store. The city engineer has kindly permitted us to publish a copy of the plans, from which the general lay-out of the various rooms may be seen; this may be compared with the plan recommended in the Ministry of Health Circular No. 2241 (December, 1940).

Personnel

Efficiency and smooth running cannot be obtained if the centre is understaffed. In our opinion the minimum number of workers in each room on each side is two. In addition to the two workers in each stripping-shed the superintendent, if male, should be in charge of the outside workers on each side, and should be responsible for the orderly admission of casualties to the centre. If the superintendent is a female then a third responsible male worker must take charge of the sheds. In the

CITY OF OXFORD: PLAN OF A GAS-CLEANSING CENTRE.

problems will lessen the effectiveness of the treatment applied to the actual burns by reason of the delay necessarily involved. To obtain the most satisfactory results speed is essential, and we must aim at securing a system of marking clothes for subsequent identification which will not unduly delay the starting of treatment. The problem is further complicated by the fact that only a limited amount of protective clothing is available for any one cleansing centre, so that the number of workers is thereby limited.

In view of the special difficulties attendant on the decontamination of gas casualties and the general organization of cleansing centres we feel that it may be of some value to describe a procedure, based on the official recommendations, which has been worked out and tested at a cleansing centre in Oxford. If this description serves only to call forth criticism of the procedure adopted it may direct the attention of the authorities concerned to some practical but none the less important problems.

In conformity with the official regulations the building that has been erected to house the cleansing centre is

shower-room one worker shall be responsible for douching the eyes of all casualties, while the other is in charge of the showers. It would add greatly to the efficiency of the centre to have a third worker in this room to assist with the eye-douching.

Following on the principle of stationing a responsible person in the stripping-shed to be in charge of admissions, we have decided that it is of greatest advantage for the medical officer to limit, if possible, his activities to the shower-room and dressing-room. By so doing he can work without the hindrance of protective clothing, can direct the treatment of any serious eye lesions, and can supervise general first-aid measures in the dressing-room. Of the two workers in each dressing-room one shall be responsible for all clerical work (patient's name, address, nature of injury, etc.); the other will supervise the dressing of casualties and will carry out first aid where required. In addition, one or two workers, depending on circumstances, will be required to take charge of the equipment store and to issue towels and clothing.

Equipment

In order to carry out the procedure of cleansing suggested here the following is the absolute minimum of equipment necessary for efficient treatment of casualties and for safety to personnel:

- 9 protective suits
- 13 pairs wellington boots
- 5 pairs protective gloves
- 5 helmets
- 5 hoods
- 12 pairs rubber gloves
- 5 rubber aprons
- 6 douche-cans with tubing and nozzles
- 2 bleach trays
- 12 buckets
- 6 bins
- 2 boot-brushes
- 4 pairs tailor's shears
- 4 pairs scissors
- 6 hand-basins
- 1 drum dry bleach
- 4 containers for bleach (tins or boxes)
- 10 hurricane lamps
- 5 electric torches
- 4 stools
- Anti-gas ointment No. 2
- Sodium bicarbonate
- Soap
- Wooden spatulas
- First-aid equipment
- Towels
- Sets of clothing
- Civilian respirators

- 1 container of dry bleach (to replenish bleach solution)
- Tray with bleach solution and brush (*Note 1*)
- 1 bucket of bleach solution
- 1 bucket of water
- 2 pairs tailor's shears
- 1 jar anti-gas ointment No. 2
- 2 wooden spatulas
- Hurricane lamps and electric torches
- File of "bag units" (*Note 2*)

Note 1.—The tray should be filled to a depth of about 1 in. with a thick suspension of bleach in water.

Note 2.—The "bag unit" consists of: (1) *Bag A*—A large numbered sack (21 in. wide, 30 in. deep); (2) *Bag B*—A slightly smaller numbered sack to which is loosely fastened a numbered tally attached to string loop for passing over patient's head. Each of the two bags and the patient's tally are identically numbered. The bags are folded up and fastened together with a single loop of cotton or a paper band so as to be readily separable.

Each member of the centre is expected to have been issued with a C.D. respirator. It will be noted that the suggested equipment exceeds the official issue in several respects.

In training the personnel of a cleansing centre it is helpful to divide their functions into: (a) duties of personnel on arrival at cleansing centre—these duties involving the setting-up of the centre in such a way that treatment may start immediately the casualties begin to arrive; (b) duties of personnel during cleansing procedure. It will be profitable here to consider these two aspects of the work separately.

Duties of Staff on Arrival at Centre

The first member of the staff to arrive must open the centre and lower all air-lock blankets. Such members of the centre as have been trained for work in protective clothing should begin to dress immediately on arrival. The first two of these workers to arrive on each side (that is, male and female) will be expected to put on full protective clothing (suits, wellingtons, protective gloves, gas-masks, helmets, and hoods) and to work in the stripping-shed. The next two to arrive on each side will prepare to work in the undressing-rooms, and will therefore put on suits, wellingtons, gas-masks, and rubber gloves. We are well aware of the fact that thin housemaid's rubber gloves do not provide a high degree of protection against mustard gas or lewisite; on the other hand, it is essential that the undressing-room personnel shall be able to work rapidly and, if the need arises, remove difficult articles of clothing unhampered by full protective gloves. We suggest, therefore, that workers in these rooms shall wear medium-thickness rubber gloves and shall take further precautions to decontaminate the surface of these gloves as described later.

Members trained only for work in shower-rooms and dressing-rooms will be expected to carry out their duties immediately on arrival. *Shower-room attendants*, having put on wellingtons and rubber aprons, must adjust the water-mixing valves and test the temperature of the water issuing from the showers. They must then fill the douche-cans with 1 to 2% sodium bicarbonate solution and hang them on hooks ready for use (nozzles should be opened till rubber tubing is filled; this will also ensure that neither tubing nor nozzles are blocked). They must then thoroughly wet all air-lock blankets. *Dressing-room attendants* must first collect and arrange the equipment in the stripping-sheds and undressing-rooms. On completion of this they will assist the dressing of any workers who have not yet finished putting on protective clothing.

When the above duties have been carried out all workers will go immediately to their posts, where they will check over the equipment and await the arrival of casualties.

Cleansing Procedure

The sequence of cleansing takes place in four stages—stripping-shed, undressing-room, shower-room, and dressing-room. The particular function of each stage in the scheme, which not only allows cleansing of the patient but also provides that he shall regain his washed clothing, is as follows:

STRIPPING-SHED

The two workers wear protective clothing, wellingtons, protective gloves, gas-masks, helmets, and hoods. (The personnel and equipment recommended in this and the following sections apply to one side only—that is, male or female.) Equipment consists of:

Procedure.—On the arrival of a casualty the worker picks up a bag unit, detaches Bag A and hangs Bag B on a hook placed in the wall about 3½ feet from the ground. The patient is instructed to stand in the tray of bleach solution, to remove the contents of the pockets of his outer clothing, and to place them in Bag B. The worker meanwhile brushes the boots with the bleach solution. All coats, skirts, and hats are now removed from casualties and placed in Bag A; any other clothing obviously contaminated with liquid gas is also to be removed and placed in Bag A. After brushing with bleach solution the boots are removed, laces being cut to speed up the process if necessary. The boots are then dipped in a bucket of water to remove excess bleach, which would otherwise damage clothing, and are then put into Bag A. Bag A is now placed in a bin to await removal to a laundry. If it is desired that each article of clothing sent to the laundry should be numbered, the contents of Bag A can quite simply be numbered individually, using safety-pins, on arrival at the laundry, or at the cleansing centre after all casualties have been treated and sent away. If splashes of gas are observed on exposed skin or hair they are treated with anti-gas ointment No. 2, applied with a wooden spatula (wooden tongue-depressors serve excellently); if obvious erythema of the skin has already developed no ointment is applied. The patient now takes Bag B and passes into the undressing-room.

It is important that the floor of the shed shall be swilled down with bleach solution, from the bucket provided, at the starting of work and at intervals thereafter.

UNDRESSING-ROOM

The two workers wear protective clothing over underclothes (or protective aprons over boiler-suits), gas-masks, wellingtons, and medium-thickness rubber gloves. The equipment is:

- 1 container of dry bleach
- 1 bucket of bleach solution
- 1 bowl of bleach solution and 1 of water
- 2 pairs scissors
- Anti-gas ointment No. 2 and spatulas
- Several changes of rubber gloves
- Latrines buckets
- 3 bins

Procedure.—Each patient is instructed to undress completely as rapidly as possible and to place his clothing in Bag B, which he has brought in with him; for speed it is desirable that the bags should be hung on hooks to facilitate the insertion of clothes. If either of the workers detects any heavily contaminated clothing that has escaped removal outside, this is to be removed from the patient and placed in a bin labelled "Clothes"; this clothing will ultimately be destroyed or, if national policy dictates that no clothes are to be destroyed, numbered pins may be attached to Bag B, one of which would now be fastened to the clothing before placing in the bin. The clothing can then be decontaminated and returned to the owner. Patients are also instructed to remove their gas-masks last, unless they are liquid-contaminated: gas-masks are then placed in a bin labelled "Respirators" for subsequent recovery. Any liquid splashes on the skin or on the hair are to be treated with anti-gas ointment No. 2 if this has not already been done. When the patient is completely undressed the numbered tally is detached from the bag and hung round the neck, and he is then passed through to the shower-room carrying his bag. In view of the limited protection afforded by the rubber gloves worn in

this room workers must be instructed to dip their gloved hand in the bowl of bleach solution provided, followed by rinsing in water, as often as possible—e.g., at five-minute intervals; further, if the gloves become liquid-contaminated they must be changed at once for a fresh pair, after washing the hands in bleach, and the contaminated gloves placed in a bin; they can later be decontaminated by boiling for two hours.

The floor of the undressing-room must be swilled down with bleach solution at the beginning of work and at intervals thereafter.

SHOWER-ROOM

The two workers wear rubber aprons over boiler-suits and wellingtons. The equipment consists of:

- Soap
- 3 douche-cans for eyes, containing 1 to 2% sodium bicarbonate solution
- 2 stools

Procedure.—On entering the room each patient, after being instructed to sit on the stool provided, is to have both eyes well irrigated. He is then instructed to step under a shower, having previously put his bag in some convenient place. When thoroughly wet he steps out from the shower and soaps his entire body; on completion of this he gets under the shower for a final rinse. Particular attention must be paid to wetting and soaping the hair. The patient finally picks up his bag and passes through to the dressing-room. If for any reason patients are unable to wash themselves this will be done by the workers, who will in any case supervise all washing.

DRESSING-ROOM

Each patient is now handed one towel and one set of clothing. Before leaving, his name and address, particulars of any injury, and number on bag are taken down. The neck-tally is given up, and he is issued with a form giving instructions as to the method of decontamination of the contents of Bag B. Ideally the contents of Bag B should be uncontaminated; in practice, however, it is very possible that this will not be the case, and we feel that in the interests of safety the bag and its contents should always be decontaminated. It is suggested that the form be worded as follows:

WARNING

The contents of this bag are dangerous. They must not be taken into the house, and cannot be used with safety until they have been decontaminated as follows:

First empty all pockets and spread the contents, together with any other loose valuables, on the ground in such a way that they are not likely to be blown away or spoiled by rain. Leave for not less than forty-eight hours. Keys and other metal objects may be taken into the house directly and decontaminated by boiling for one hour in plain water.

All clothes and the empty bag should be hung out of doors and left for not less than forty-eight hours; all articles that will stand it should then be boiled for two hours in plain water.

Immediately after handling these articles the hands must be well washed with soap and water.

The empty bag is subsequently to be presented at the distribution centre in exchange for the decontaminated outer clothing.

When the attendant in the dressing-room is satisfied that all these steps have been carried out, the patient is provided with a fresh gas-mask and is allowed to leave the building.

Discussion

In order to prevent vesication after contact of the skin with mustard gas or lewisite it is well known that treatment with soap and water must be begun within ten minutes, and that this interval should be reduced as much as possible if the best results are to be obtained. If contamination of the eyes has occurred early treatment is even more essential.

The decontamination procedure outlined above is an attempt to define and standardize the duties of the various workers at a cleansing centre in such a way that washing with soap and water may be started at the earliest possible time coincident with (a) a system of marking the clothing for subsequent identification and (b) the safety of the personnel of the centre. In the interest of speed, therefore, we have attempted to eliminate so far as is possible the responsibility of any member of the personnel to decide whether contamination of a particular article of clothing or of any part of the body has or has not occurred. It is for this reason that we have adopted the policy of removing all outer clothing in the stripping-shed and of irrigating the eyes of every casualty. At the same time, if, in the course of his duties, a worker happens to detect gross contamination of the skin or hair we have suggested that anti-gas ointment should be applied in case of any subsequent delay in getting under the showers. Anti-gas ointment will also obviously be of use in the accidental contamination of any of the workers. Further, it is in order to accelerate the process of undressing that we have adopted the use of rubber gloves in place of the official protective gloves for the workers in the undressing-rooms.

In view of the difficulty experienced by workers in giving verbal instructions to casualties while wearing respirators we suggest that notices printed in bold type should be exhibited in the stripping-sheds and undressing-rooms, giving concise instructions concerning the more important points of procedure. The notices that we are using are worded as follows:

For the stripping-shed:

READ THIS

1. Do not remove gas-mask.
2. Step into bleach tray.
3. Place contents of pockets in small bag.
4. Remove outer clothing and place in large bag.
5. Remove boots and give to assistant

Act Quickly and Obey Orders.

For the undressing-room:

READ THIS

1. Do not remove gas-mask.
2. Undress quickly and place clothes in bag.
3. When undressed go to assistant.

In the event of a large number of casualties arriving for treatment it would be helpful to exhibit a notice in the dressing-room giving instructions that no one must leave the centre before being issued with a new gas-mask; it will be remembered that these are not issued until the workers are satisfied that all other formalities have been carried out.

One of the greatest difficulties that we have experienced in training several teams of workers is the irrigation of the eyes; if blepharospasm is present it will be almost essential for the medical officer to take charge of the douching. In order to be in any way effective irrigation must be copious, and we are of the opinion, therefore, that three douche-cans should be an absolute minimum in any shower-room; on this basis two cans can be in use at any time, with a third in reserve to be used while the others are being refilled. It should be pointed out that if the employment of sodium bicarbonate solution involves any delay in filling or refilling the douche-cans warm water should be substituted; if douche-cans are unavailable or if any difficulty is experienced in their use by members of the personnel a large teapot will serve excellently and will have the added advantage of greater capacity. It will be noticed that in this procedure irrigation of the eyes is carried out in the shower-room. In spite of the fact that irrigation

should be begun at the earliest possible moment after contamination we are of the opinion that this should not be done by workers in the undressing-room; these workers will be wearing respirators and rubber gloves, and we feel that under these conditions it would be almost impossible to irrigate contaminated eyes effectively, and that an attempt to do so would only cause delay and possibly spread contamination. It might be argued that it is neither necessary nor even advisable to wash the eyes of every patient, and that it would perhaps be an advantage to restrict irrigation to those with obvious contamination of the eyes or who give a history of suspected contamination. All casualties, however, should be instructed to seek medical advice if ocular symptoms develop in the course of the next twenty-four hours.

The treatment of liquid-contaminated hair presents a difficult problem. Undoubtedly the most satisfactory method would be to cut off the affected hair; such a practice, however, particularly in the case of women casualties, might be strenuously opposed, so that a considerable delay might occur while persuading the casualty to allow the hair to be cut. It is for this reason that we have proposed the application of anti-gas ointment to the contaminated patch, while at the same time issuing instructions to the personnel to cut off the hair if this can be done quickly and with the consent of the patient.

We have not attempted to discuss here the difficult question of the cleansing of those who are also wounded. With a personnel trained in first aid most minor cases could almost certainly be taken by following this procedure. Stretcher cases obviously present special problems, though in a sense the treatment is simplified, since in these cases the marking of all clothing for subsequent identification is of very secondary importance.

Conclusion

We would like to point out that we are presenting an account of the above procedure solely because of the lack of detailed guidance that has been offered with respect to the many difficult problems arising during the working of a public cleansing centre. The only claim that we make regarding the procedure is that it has been tested at many practice exercises, and the cleansing of unwounded patients has been carried out with, we feel, the minimum of delay.

We would like to thank Dr. G. C. Williams, the medical officer of health, and the staff of the public health department of the City of Oxford for the help they have unfailingly given us in the organization of this cleansing centre; and also the personnel of the centre for their ready attendance at many practice exercises. Our thanks are also due to Dr. R. B. Fisher for many helpful suggestions.

GALLANTRY IN CIVIL DEFENCE

In a *Supplement to the London Gazette* dated September 12 the award of the M.B.E. (Civil Division) to Dr. JOHN JOSEPH MCCARTHY, medical officer, mobile unit, Islington, is announced. The announcement reads as follows: "Bombs demolished houses, gas and water mains were fractured, and people were trapped in the wreckage. Dr. McCarthy worked with the rescue party and repeatedly entered a gas-laden tunnel to attend to casualties and administer oxygen to a trapped man."

The name of Dr. GRACE ELIZABETH MCCKEY, medical officer in charge, first-aid post, Liverpool, has been brought to notice for brave conduct in civil defence.

The names of Dr. GEOFFREY GORHAM HOLMES, medical officer, mobile first-aid unit, Bishop's Stortford, and Dr. GAVIN HAMILTON LIVINGSTONE, surgeon, Oxford, have been brought to notice for brave conduct when aircraft crashed and caught fire.

STATE OF PUBLIC SHELTERS IN LARGE CITIES

SUMMARY OF RESULTS OF SPECIAL INVESTIGATION

The shelter situation in London, in particular the improvements which have been effected since last winter, was the subject of an article in the last issue (p. 414). Below are summarized the results of an investigation on behalf of the *British Medical Journal* which has extended to seven principal cities of Great Britain. Once again we have to acknowledge the very great courtesy and help afforded by the officials of the various authorities concerned and by representatives of voluntary agencies. All the information set down has been obtained at first hand by personal visits to different types of shelters in the various towns.

In the large cities of Great Britain the shelter problem is much the same as in London, except that when raiding occurs it is likely to be more concentrated and therefore more devastating in its immediate effects upon the community and the public services, so that a larger proportion of the population seek shelter. In Liverpool, for example, it is estimated that 75% go to shelter every night, and 95% if there is an "alert." Another feature of badly raided cities which does not present itself in London is the nightly trek out of the city into the country. Outlying parish halls and such places have been sometimes opened up for these refugees, but many sleep in buses, others go to barns and other farm buildings, and not a few sleep in hedges and fields, with deleterious results to health.

The Position in Bristol

Bristol has 1,150 shelters, including communal and surface, but not Andersons. The city is divided into five sections for A.R.P. purposes, each division with its own organization, which is co-ordinated by central control. There are eleven medical aid posts, with nurses in attendance and doctors at call. Doctors must, however, be summoned by a responsible official, but in addition they visit shelters for routine health inspection. There are first-aid points in every dormitory shelter, which can be opened by nurse or doctor. One or two dormitory shelters have their own canteen, but the authorities discourage the making of shelters into "clubs." Dormitory shelters are sprayed and cleaned out every day. Very little infestation has been noted. The number of children who go regularly to the shelters—about 1,200 even in the middle of summer—gives rise to some disquiet.

One of the Bristol shelters is a tunnel, in which thousands of people congregated under very bad conditions at the beginning of last winter. The tunnel has now been lined with corrugated iron and turned into quite a good shelter, with a first-class medical aid post, built by the shelter marshal, a former Navy man. Nurses with V.A.D. training visit during the day the homes of the frequenters of small shelters. Bristol insists on bedding being removed from shelters every day.

Some very good concrete surface shelters were found in Bristol, but they were unused, although superior to some basements for which the public showed a preference. Some of the basement shelters seemed cold and gloomy. One, however, under a factory was well aired and warm. Cura stoves are being fitted in the trench shelters.

Shelters at Cardiff

There are groups of ten to twenty shelters, each shelter being something over 30 ft. long, with roofs, walls, and floors of solid monolithic construction, and with a layer of concrete skin on the foundations, the value of which is stated to be that should a bomb fall in the vicinity, while the building might "bounce," it would immediately return to its original position. Each of the two hundred or so buildings is to contain 48 bunks in two tiers, with reasonable space between each, and a plywood screen at the bunk head to prevent droplet infection. The sanitary

annexes are in reinforced brick. Both water-closets and chemical closets are provided for each building, but the chemical closets remain closed unless there is interference with drainage and water supply. The buildings, all of the same pattern, are well ventilated by extractor fans, the bar type of electrical heater is fixed to the walls, and water is on tap. Each group has a medical aid post. At shelters situated from two to five miles from the people's homes it is not possible to insist on the removal of the bedding each day, but airing lines are provided on the adjacent land. At each group there is a paid shelter warden, assisted by a number of voluntary workers, and a superintendent is in charge of the whole service. A debatable matter is the use to which such ambitious building can be put when the war is over. No doubt it can be used for temporary accommodation while the city's rehousing scheme is in progress.

Of the shelters in Cardiff itself the most interesting is the grim but apparently impregnable shelter in the castle wall. The Middle Ages seem back again with the St. John orderlies and nurses on duty all night in the castle gatehouse. Deep basement shelters cannot be provided in Cardiff owing to the nature of the soil and the nearness to sea level, which might result in flooding. No disease is reported from the shelters, and, generally speaking, the health of the city is no worse than in normal years, though there is a certain amount of scabies. Here as in Bristol the curious preference of the public for overcrowded basements under buildings, although good-type concrete shelters were available, to some extent thwarted the authorities.

Dispersal Policy in Birmingham

The shelters in Birmingham consist of large and small basements, trench shelters in bigish groups, a few surface shelters in which no one sleeps, and domestic communal shelters. During the winter the big basement shelters were overcrowded. The general policy of the authorities here is to discourage the aggregation of people in large shelters, but owing to shortage of materials a check has been put upon the number of communal shelters which the city can provide. Birmingham had a partially completed programme of domestic and domestic communal shelters when the Ministry of Health stepped in, and the programme when it is carried through will not be anything like the one originally planned. One of the largest shelters has been closed because it was found impossible to improve its condition. There is only one shelter in Birmingham with more than 500 bunks. Medical aid posts have been installed in some shelters, but in one or two instances have been closed down owing to lack of use.

Chemical closets generally have been installed in the Birmingham shelters. It was stated that the need for water-closets had not been experienced, and that these had the disadvantage of readily becoming fouled and of not being properly cleaned. A point was made of adequate lighting in lavatories as a means of preventing misuse. For artificial heating Cura stoves have been tried but have not proved successful, and preference is given to insulated wire heaters. Fans have been put in basement shelters where ventilation is unsatisfactory. The Birmingham shelters have not been bunked to capacity, which leaves more room for people to move about. A good feature of the steel bunks is the arrangement to ensure a hygienic distance between each sleeper. A criticism which must be made relates to the lighting. In the early days the shelters were lighted fairly adequately, but the people desired the lights to be lowered during sleeping hours, and 15-watt lamps were put in, resulting in far too dim an illumination. In many of the shelters also the only alternative lighting system, should the mains be put out of action, is by candles.

A large amount of the minor medical work in the shelters is carried out by the lay members of the Friends Ambulance Unit, but when it seems necessary they get people to go to their own doctor or the hospital, probably sooner than they would go otherwise. Scabies was reported to be very heavy during spring and summer, just how heavy is not known; but reports from various quarters, including school medical officers and factory surgeons, confirm it. It is attributed to the habit of people of sleeping in their clothes in the home as well as at the shelter. An increase in head-lice infestation has been reported, with odd cases in the shelters.

Manchester's Achievement

One of the most interesting shelters in the country is to be found at Manchester. It has been paved, the walls and ceiling lime-washed, the spaces bayed and bunked, with drinking-fountains, washhand basins, and water-closets to each bay. It has a medical aid post and a canteen. The people who use this shelter are for the most part very poor. The doctor in charge said that at first he and the nurses met with a good deal of hostility, but gradually people became more friendly, and their standards of hygiene are also improving.

Manchester has 380 deep basement shelters, affording accommodation for 75,000 people, and there are innumerable trench and surface shelters as well as a number of private ones. One shelter has been cream-washed, concealed lighting has been put in to very good effect, it has been air-conditioned, and is warmed with Cura stoves in the winter months. Bunks are wooden, with canvas mattresses. There is a medical aid post and a very attractive canteen.

The incidence of infectious diseases in Manchester is said to be lower than ever before. Some 20,000 children have had diphtheria immunization since last February. There has been an increase in scabies, but this began before the shelters were bunked; it has not been traced to shelter life, and is an expected accompaniment of war conditions.

Special Problems in Liverpool

The policy in Liverpool is one of general dispersal, but it is recognized that this is impracticable until the small shelters are made fit for habitation. The authorities here, as elsewhere, have to reckon with the desire of the people for company and for the "feeling" of security which belongs to a basement or a large shelter. Liverpool has also a serious problem, which does not seem to have arisen to the same extent elsewhere, in the extraordinary amount of damage done by children to its brick and concrete shelters. A whole range has had to be pulled down owing to this damage, and photographs make it difficult to believe that the damage has not been done by bombs. It is another illustration of how evacuation and shelter problems interlock.

The shelters are regularly inspected and dirty or lousy bedding is removed. The biggest trouble is reported to have been from fleas, the consequence of demolition work during dry weather. But health conditions generally have been good. One of the largest shelters in Liverpool is in two portions, one fitted with ticketed bunks and the other with unticketed seats on which people can recline. There are heater fans thermostatically controlled, which can also be switched on and off by wardens. The washing places have hot and cold water, and hot-water boilers have been installed. There is an excellent medical aid post, where it was noted that the sink was fitted with surgeon's taps.

The domestic communal shelters are being improved, bunked, adequately lighted, and are having a special type of concrete box heater put in. The shelters are kept locked and the key left with a responsible householder. Some concrete trench shelters are very small but have a high factor of safety. In these narrow shelters the people could never be allowed to forget that an air raid was proceeding, as they might do in larger shelters where there was plenty of movement. A large basement shelter, which was being reconditioned and will be attractive when complete, was also visited. Liverpool is fortunate in its officials, who are doing all they can to bring their shelters to a high degree of excellence.

The Glasgow Shelters

Glasgow suffers to some extent from lack of unified control. The general policy here again is dispersal. Over 15,000 shelters (including Andersons) for single families or other small groups have been put up, and there is actually shelter accommodation of one sort or another for one million persons, nearly equal to the entire population of the city. One type of shelter is peculiar to Glasgow—namely, the strutted close (or entrance to tenement), which has been found to stand even if the rest of the building collapses. Unless raids become much more frequent the Glasgow people will not be encouraged by their authorities to sleep in shelters. Definite cases of tuberculosis

(which is on the increase in Glasgow) have arisen from shelter life, and bronchitis and pneumonia in children have been attributed to shelter chill. No actual epidemics have been experienced, but trouble has arisen, here as elsewhere, from scabies.

In a large basement shelter some concrete seats were seen. Nurses sleep in this building, and when the shelters are opened, which is not until an "alert" is sounded, go to various points in the city where there are aid posts. In another very popular shelter, open all day, and with a paid warden always on duty, there were well-placed bunks and a first-aid room. Here there were chemical closets, but an endeavour is being made to get water-closets sanctioned.

In one large range of trench shelters in this area, which are occupied every night, the people sleeping on seats, large masses of cotton-wool-like fungi were noticed on the wooden walls, and the shelter seemed to be extremely damp and untidy. There were other concrete shelters near by where conditions were much better, but the people here again were erratic in their preference. In these shelters, by the way, drinking-water (chlorinated) was stored in urn-like containers, refilled once a week. Glasgow is one of the authorities with a definite "Anderson shelter policy." The Andersons are erected by the city engineers and properly drained so that they are always usable. The use of domestic communal shelters erected in gardens and yards is also being encouraged. These are lighted and fitted with Cura stoves, bunked and seated, and "let" to families or groups of families, who look after them and have their own key. They are approximately square in shape and quite roomy.

Model Medical Aid Post at Newcastle

In Newcastle-upon-Tyne there are two deep shelters, some twenty-two basements, and two surface shelters used as dormitories. Bunks have been installed in Anderson shelters, and a supply of Morrisons, several hundred a week, is proceeding. Some of the Andersons are usable, but others are said not to be, and there have been complaints of liability to flooding.

Two Newcastle shelters were visited. One was a basement under a factory. It was reinforced by concrete and had a concrete floor. It contained three sick bays, the bunks of which were ordinary ships' bunks, very comfortable, and there was all the necessary sick-room equipment. In shelters holding fifty people the sick were provided for in screened-off bunks, and in the larger shelters with 250 there were special sick bays.

Newcastle's most interesting shelter was laid down early in 1939. It has a concrete floor and bunking capacity. It is very dry, and temperature conditions are good. It has a hot-water supply, and washing-basins, fountains, and water-closets are grouped along the culvert, which is wide and high. A large seated area could be adapted for recreational purposes and a canteen. A system of alternative lighting by hurricane lamps has been installed.

Special attention was drawn here to the medical aid post in course of erection. "Hospital" would be a better description. It was claimed to be unlike anything else in the country. It includes a waiting room, a consulting room (with wash basin), and two wards, each to take six hospital beds and twelve two-tier ships' bunks. There are two water-closets, one for each ward, and two isolation cubicles with their own lavatory. There is plenty of cupboard room and a well-fitted kitchen, with hot-water geyser, sink, and draining board. Three nurses are to be attached to this post, two on duty every night, with a doctor visiting by schedule. One small room can be used as an infant feeding clinic or additional doctor's room. Newcastle has a woman warden service which is proving very satisfactory. These wardens, who are paid, work on eight-hour shifts, which enables them to get sufficient rest and attend to their homes. They are women of the "comfortable" motherly type.

Of the large provincial cities it may be said that, although the state of affairs with regard to shelters is unequal, and everywhere there is something that might be better as well as much that is very good, some of them have quite a lot to teach the London authorities. Some general comments are made in a leading article on page 443.

THE CHANGING PHARMACOPOEIA

A fourth Addendum to the *British Pharmacopoeia*, 1932—the third to be published during the war—becomes official from October 1. It contains twenty-nine new monographs and emendations of many others; a list was given in the *British Medical Journal* of September 6 (p. 351). The object of the British Pharmacopoeia Commission has been to recognize new preparations which war experience has brought to light and also to make whatever changes are possible in the interests of economy without creating unnecessary difficulties for the medical profession, pharmacists, or manufacturers. Standards have been provided for preparations to appear in the War Emergency Formulary, a compilation on which a Ministry of Health committee has been sitting since the beginning of the present year and which is at the point of completion. This committee has taken as the basis of its work the memorandum "Economy in the Use of Drugs in Wartime," prepared by the Therapeutic Requirements Committee of the Medical Research Council. Prof. J. A. Gunn, chairman of the Commission, is a member of both these committees, and Dr. C. H. Hampshire, secretary of the Commission, is secretary also of the Therapeutic Requirements Committee and a member of the committee of the Ministry of Health.

There will also be found in the new Addendum descriptions of and standards for certain chemicals formerly supplied only as proprietary preparations, several of them imported from Germany. Examples are suramin, which replaces "Bayer 205," used in the treatment of trypanosomiasis, and pamaquin, which replaces the proprietary "plasmoquin," used in the treatment of malaria. Sulphanilamide is an obvious introduction, but patent rights preclude other members of this group, such as sulphapyridine. The inclusion of digoxin, a proprietary preparation still covered by patents, indicates a relaxation of the practice excluding articles in respect of which a monopoly exists. Some changes are made owing to absence of ordinary sources of supply—for example, Indian squill in place of Mediterranean squill; alterations in the values on test of halibut-liver oil to admit oils from the Pacific coast; and the inclusion of a synthetic optically inactive menthol in view of the lack of the imported natural material from Japan and the synthetic material from Germany.

Changes in Pharmaceutical Procedure

Important changes in pharmaceutical procedure are made known in an appendix containing a revision of the methods of sterilization of solutions and suspensions intended for parenteral injection. Tyndallization, or sterilization by discontinuous heating, has been found unreliable in dealing with infective spores. The method now adopted is heating at 98–100° C. in presence of a bactericide. Bactericides specified are chlorocresol in the proportion of 0.2% or phenylmercuric nitrate 0.002%. A method of filtration is specified, but it is laid down that any solution prepared by filtration must be submitted to and comply with the tests for sterility. One of the most important of the new injections included is injection of procaine and adrenaline of 2% strength. Directions are given for sterilizing by chlorocresol, sodium metabisulphite being added as a stabilizer. No doses are given, the dosage being left to the discretion of the prescriber. Two other well-known injections now included are of sodium morrhuate and of quinine and urethane, and here again careful directions are given for sterilization by addition of chlorocresol. Injection of calcium gluconate is another new inclusion, sterilized by heating in an autoclave. A note is added that the injection must be completely free from solid particles.

Injection of nikethamide is also included as the equivalent of coramine; here sterilization may be by heating in an autoclave or by filtration. Another new preparation is solution of sodium hydroxide, introduced because of the difficulty of obtaining potassium compound. Morphine sulphate finds a place as the salt now most commonly used for hypodermic injection, morphine tartrate having fallen almost completely out of use. Sterilization of the solution for parenteral injection is by heating with a bactericide or by filtration.

Some Additions to the "B.P."

Some of the other additions may be briefly mentioned. They include mandelic and nicotinic acids, the latter indicating that the Commission is following the work on vitamins closely. Benzyl benzoate, much required in view of the increase in scabies, is inserted; also bismuth subgallate, formerly known as "dermatol," used as an antiseptic dusting powder. Ephedrine hydrochloride was already in the *Pharmacopoeia*, but the alkaloid itself is now included for the purpose of making oily preparations, sprays, and the like. Light liquid paraffin, suitable for sprays, is another new inclusion. These introductions may foreshadow the inclusion of spray solutions in the next complete volume. The War Emergency Formulary will include sprays, and it was desired by the compilers of the Addendum to furnish a standard material. Proflavine sulphate has been brought in because of the widely expressed preference for this substance as against acriflavine. It has the disadvantage of low solubility, and possibly at a later stage further improvement may be effected by the adoption of some other acridine derivative. Hydrochloride of proflavine is a much more soluble salt, but the sulphate has been known for so long that it was felt difficult to make a change. Magnesium trisilicate is now defined and standardized.

Changes for the Sake of Economy

Other new inclusions are sodium metabisulphite, chiefly used as an anti-oxidant in the preparation of solutions containing adrenaline; exsiccated sodium sulphate, the use of which it is considered desirable to encourage in preference to magnesium sulphate in wartime; and sodium lactate as a substitute for glycerin in making a kaolin poultice.

Glycerin wherever it is considered unnecessary has been eliminated. The emendations here are permissive, not obligatory; glycerin may be omitted from the compound tinctures of cardamom and of rhubarb and of ipecacuanha. Glycerin of tannic acid may now contain no glycerin: the tannic acid is dissolved in distilled water and the solution thickened with tragacanth. Syrup of wild cherry or virginian prune is made according to a modified formula with tragacanth and sweetened with saccharin. Further changes are made in mercurial ointments. A dilute ointment of mercury containing 10% of the element is now defined in addition to the ointment containing 30%.

Finally, potable water is recognized in place of distilled in making a number of preparations. This is a measure of economy because it saves cost of transport if distilled water is demanded. Moreover, storage of distilled water may give rise to difficulties in dispensing. Preparations affected by this change are aromatic waters, camphor water, chloroform water, and a large number of infusions. In view of the chlorination of water supplies and the hardness of certain natural waters, this permission will doubtless be exercised with discretion by the dispenser in order to avoid incompatibilities.

The British Pharmacopoeia Commission is to be congratulated on producing an Addendum which while meeting the war situation in various ways causes no obvious therapeutic disadvantage. It is the more praiseworthy because the work has been done notwithstanding the destruction of the Commission's offices by enemy action.

FEEDING THE CHILDREN

It is evident that a small number of well-run canteens will not solve the problem of feeding the country's children as a whole, and figures so far received by the Children's Nutrition Council¹ show that in many areas less than 5% are catered for, while perhaps only 15 or 20% of the local authorities are providing meals for one-tenth of their children. School milk schemes, on the other hand, are proceeding well in spite of occasional difficulties in obtaining deliveries at the schools. But, although consumption figures have risen higher than the best pre-war averages, there is still room for improvement. It is possible, for instance, that not more than one-third of the authorities are able to show that over 60% of their scholars have the daily third of a pint. Several areas have reported shortages of milk towards the middle and end of July. The problem of supplying milk during the holidays has been met successfully by Glasgow, where sixty-six special milk bars were opened and 40,000 children attended. Various holiday schemes have been drawn up in other areas, but in many districts the response was poor.

The National Milk Scheme, whereby expectant and nursing mothers and children under 5 are supplied free or at cheap rates, has now been operating for slightly over a year, and by last May the number of those benefiting was 2,600,000. By the end of July 73% of those entitled to take advantage of the scheme were doing so. Free milk is available where parents have a weekly income of 40s.; the qualifying scale for one parent is 27s. 6d., and 6s. is added to the scale for each non-earning dependant. At the end of July 29% of all those registered under the scheme were receiving free milk.

Milk Powder

It has been announced that dried milk powder will supplement supplies of liquid milk. This is to be dried skimmed milk imported mainly from the United States and Canada and from New Zealand, and is to be experimentally released for sale in the North-East on October 1. The available condensed milk and milk powder should equal 150 million gallons of liquid milk, bringing the total supply to an average of 100 million gallons a month, the supply in the worst months being between 70 and 80 million gallons. During the winter an adult couple should receive four pints of liquid milk a week, together with a further three pints made up from condensed milk or powder. A family of six with two under 5 and two under 17 should get twenty-five pints of liquid milk a week, exclusive of what is obtained at school. Those benefiting under the National Milk Scheme will receive their pint a day, and children up to 17 will have priority for half a pint per day in their homes. According to present decisions there is to be no strict rationing of milk, and vendors will be able to dispose of any surplus as they wish.

Advance publicity for the dried milk scheme is necessary in order that consumers shall know its properties and use. Skimmed milk is without the fat of milk and without vitamins A and D, but it should supply a valuable addition to animal protein. The Children's Nutrition Council suggests that the four chief vitamins and iron might be added to the powder. The dried milk will be issued with a warning that it should not be used for infant feeding, and it will be employed mainly for cooking. Experiments show that it does not precipitate in tea, but that it needs careful mixing when reconstituting it in liquid form. The price has not yet been fixed. The Ministry of Food believes that the novelty of the milk will protect it against a sudden demand, but the Children's Nutrition Council is doubtful whether the policy of issuing it through the retail trade without rationing is wise, especially now that the public has been warned of a possible milk shortage.

¹ War-time Nutrition Bulletin, No. 12, September, 1941.

Local News

ENGLAND AND WALES

Chadwick Public Lectures

On Tuesday, October 7, at 2.30 p.m., the first lecture in the autumn programme of the twenty-ninth annual series of Chadwick Public Lectures will be given at the Royal Society of Tropical Medicine and Hygiene, 26, Portland Place, W., by Mr. V. Zachary Cope on "The Influence of War on Surgery," with Sir William J. Collins, chairman of the Chadwick Trustees, in the chair. Other lectures, all at 2.30 p.m., have been arranged as follows: October 28, at the Royal Sanitary Institute, 90, Buckingham Palace Road, S.W., Mr. J. C. Dawes (Ministry of Health), "The Cleansing of Towns and Cities"; November 11, at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, W.C., Bossmom Gift Lecture by Mr. F. R. Hiorns, "Hygiene Technique in Building, or the Economic, Psychological, and Health Aspects of Surface Treatment"; November 27, at Westminster Hospital Medical School, 17, Horseferry Road, S.W., Dr. S. Ernest Dore, "Advances in Dermatology during the Past Forty Years"; December 9, at the Royal Society of Tropical Medicine and Hygiene, Mrs. Blaise Gillie, "Post-war Housing in the Light of Wartime Experience."

Cancer Research in Yorkshire

The Yorkshire Council of the British Empire Cancer Campaign, which owed much of its original stimulus to the late Lord Moynihan, is continuing its work, although limited by war exigencies. The fifteenth annual report embodies an account of the work of the Department of Experimental Pathology and Cancer Research of the University of Leeds, and of the Field Laboratory of the University of Sheffield. The Field Laboratory has been improved during the year, and a new tissue culture laboratory equipped.

At Leeds Prof. R. D. Passey describes experiments following upon an American report of the experimental production of bladder papillomata by the administration of commercial β -naphthylamine, one of the amino-compounds used in the aziline dye industry. The experiment at Leeds began in August, 1937, when four dogs received 100 mg. daily of this specially purified compound. After an initial period of haematuria the dogs remained well for a year, when one male dog died from a generalized lesion resembling Hodgkin's disease, but without bladder tumours. The female has now died (after three and a half years' treatment) with extensive multiple papillomatosis of the bladder with the microscopical characteristics of malignant new growth. The two surviving dogs are in good health. This so far as it goes confirms the American work that bladder tumours are induced by purified amino-compounds. So far in America the condition has been induced in bitches only, and at Leeds also it was in the bitch that it appeared. The possible antagonism between one malignant tumour and the appearance of another in the same animal has also been investigated at Leeds, but the experiments carried out so far suggest that no such antagonism exists.

At Sheffield Prof. H. N. Green and his co-workers have been engaged in studying the complementary action of viruses and chemical carcinogens in the production of malignant mammalian tumours. Thirty-two rabbits bearing Shope papillomata were divided into three groups. One month after the appearance of the papillomata the first two groups received injections of thoro-trast and methylcholanthrene respectively into the base of the warts. In the third group, which acted as control, some of the animals received injections into the warts of lead peroxide, others of sesame oil, and the remainder were not injected. Fifteen months after the inoculation with virus seven animals treated with the carcinogenic agents survived, but none of these, or of the control animals, had developed a malignant tumour, though all had either growing or stationary papillomata. This is an unusual result, as malignancy generally supervenes in Shope papillomata grown in domestic rabbits, even without interference to the warts, in a much shorter period. It is thought possible that the carcinogen modifies both virus and host cells and that the modification of either of these alone is ineffective; also that the combined application of a chemical carcinogen and material

which should contain the hypothetical modified virus might result in a shortening of the latent period of tumour development. An attempt has been made to test this last hypothesis, but the experiments so far give no support to it.

Correspondence

Abortus Fever and Sulphapyridine

SIR.—I have read with great interest Dr. J. Whittingdale's letter (August 9, p. 210) describing a case of undulant fever (*Brucella abortus* infection) treated with sulphapyridine and Dr. J. H. F. Pankhurst's letter (August 30, p. 318) criticizing Dr. Whittingdale for concluding from the results in his case that "*Brucella abortus* infection responds to sulphapyridine." After reading these two letters it occurred to me that a few comments based on my series of 522 cases, of which 63 were treated with sulphonamide compounds, might be useful. Dr. Pankhurst's criticism is based upon the capricious behaviour of "a disease which is notorious for its intermissions and relapses." I agree with him that such a caution is very necessary, and I have repeatedly drawn attention to this point. Thus in an article in *the Lancet* I remarked: "The rapid return of the temperature to normal followed by recovery will often tempt the doctor to ascribe this happy result to the particular treatment which immediately preceded this occurrence; but all experienced observers are agreed that such a sudden termination is common in untreated cases and should therefore be interpreted with great caution"; and again: "Cases in which afebrile and sometimes symptom-free intervals of several months or years were followed by recurrence of the typical disease without any evidence of reinfection present a difficult problem, but various considerations suggest that the *Br. abortus* may lie dormant (e.g., in the spleen or lymph glands) for long periods." My experience since writing the above has only served to confirm these views, and Table I gives a few instances in my series of striking intermissions of the fever in cases of this disease.

TABLE I.—Intermissions of Fever in Cases of Undulant Fever

Case No.	Intermissions
	1st intermission
21 ²	2nd " 2 days
	3rd " 3 "
	4th " 38 "
	5th " 45 "
	6th " 122 "
217	1st " 37 "
	2nd " 35 "
372	1st " 94 "
	2nd " 111 "
393 ³	1st " 28 "
	2nd " 23 "
480 ⁴	1st " 4 weeks
	2nd " 1 week
	3rd " 1 "
493	1st " 12 months
	2nd " about "
	3rd " 59 days
504	1st " 3 "
	2nd " 3 "
	3rd " 3 "
	4th " 3 "

It will be clear from these few examples that the effect of any treatment must be extremely difficult to determine in such a capricious disease, as Dr. Pankhurst aptly calls it. What criteria can we use? Obviously the return of the temperature to normal following the administration of sulphonamide compounds is insufficient in itself, as not only might apyrexia have occurred without such intervention but it may merely be a temporary intermission. The complete disappearance of symptoms is a better criterion, as most intermissions are not, in my experience, found to be completely symptomless; but this criterion is certainly not an absolute one. Again, the disappearance of specific agglutinins from the blood serum is a useful guide, but this usually takes many months or even a year or more. For practical purposes I think it is better to avoid any decision as to "cure" and to divide the cases into those in which the drug

¹ Dalrymple-Champneys, Sir W., *Lancet*, 1935, 2, 1449.

² MacArthur, W. P., and Wilmson, J. B. A., *British Medical Journal*, 1930, 1, 855.

³ Kato, D., and Lacey, C. R., *Lancet*, 1937, 2, 77.

⁴ O'Reilly, T. J., *ibid.*, 1938, 2, 450.

appears to have conferred definite benefit upon the patient, those in which the benefit is doubtful, and finally those in which no benefit can be detected. The category into which any case shall be put is then determined from experience, taking into account the probable course of the disease if it had remained untreated (admittedly a difficult point to determine), the duration and intensity of the treatment, the change in the agglutinin titre, and the duration of apyrexia after treatment. On these lines I have ventured to classify, as shown in the following table, the 63 cases in my series in which sulphonamide compounds were given, including the 12 cases in which the information available was insufficient to determine the efficacy of the treatment.

TABLE II.—Results of Treatment of Undulant Fever with Sulphonamide Compounds

Drug	No. of Cases Treated	Result			
		Definite Benefit	Doubtful Benefit	No Benefit	Insufficient Information
Prontosil rubrum ..	17	4	2	6	5
Prontosil album (streptocide, sulphonamide-P, sulphanilamide)	26	12	5	5	4
Proseptasine (M & B 125, 46 R.P.) ..	2	0	0	1	1
Soluseptasine ..	1	1	0	0	0
Sulphapyridine (M & B 693, daganan) ..	14	4	4	4	2
Prontosil soluble (Bayer 102, rubiazol injectable) +					
Prontosil album ..	2	2	0	0	0
Prontosil album +					
Br. abortus vaccine	1	1	0	0	0

In the first column of Table II I have given the different synonyms of each compound used (for the sake of brevity I have not included the chemical names), and I would like to call attention to the confusion caused by the loose employment of these names in the descriptions of cases, a source of error from which my records are certainly not altogether free, but which I have tried to eliminate so far as possible by inquiries in cases in which I suspected misdescription. The commonest confusion is probably between prontosil rubrum and prontosil album, but others certainly occur.

As regards the proper use of these drugs in undulant fever, while fully agreeing with Dr. Pankhurst as to the dangers attending the indiscriminate and prolonged use of sulphonamide compounds, especially in children, the administration of these drugs in small quantities for a very short time, as in some of the cases in my series, cannot be expected to control the infection or to yield any information on which the value of these drugs in undulant fever can be assessed.

Finally, may I take this opportunity of appealing once more to practitioners to send me particulars of any cases of this disease which occur in their practice, for inclusion in the records which I have kept since 1928 for the Ministry of Health and the Agricultural Research Council. These records are, of course, confidential, and are used only for statistical purposes.—I am, etc.,

W. DALRYMPLE-CHAMPNEYS.

Ministry of Health, Whitehall, S.W.1, Sept. 6.

Speed in Wartime Surgery

SIR,—I have read with much interest the two articles on the clinical observations on air-raid casualties by Drs. R. T. Grant and E. B. Reeve (August 30, p. 293, and September 6, p. 329). Their conclusions, particularly with regard to shock, are of much importance, and I hope that their researches will be extended.

They have, however, described two cases which, from a surgical point of view, seem to me to call for comment. (1) A man who had a double amputation performed through the left thigh and through the right knee-joint. This was done by two surgeons working together, and it is stated that the operation "lasted only forty minutes"; about a pint and a half of blood was lost. (2) A man with a penetrating wound of the abdomen had one perforation of the descending colon, three perforations of the jejunum, and a tear in the mesentery; these were sutured, the operation lasting one hour.

Surgeons operating in France after the first year of the last war could have done the first operation without appreciable loss of

blood in well under five minutes. The second operation would not have taken much more than half an hour. In peacetime, surgery, very rightly, should be done with meticulous care and without undue haste, but wartime surgery is a very different proposition. In such cases as the two described speed is essential; every minute saved may increase the chances of recovery in a badly shocked patient. Those surgeons who are doing war surgery for the first time should remember and try to emulate the dexterity and speed of our ancestors, who had to do their amputations like lightning.—I am, etc.,

Cardiff, Sept. 17.

J. BERRY HAYCRAFT, F.R.C.S.

Voluntary Hospitals

SIR,—The difficulty which Sir Frederick Menzies finds in ascertaining what are those good points in the voluntary hospital system which are lacking in the municipal hospital system will be easily appreciated by those who, like myself, have worked under both. The differences in the two systems may be easily sensed but hard to define. Perhaps the following remarks may serve to emphasize a cherished feature of the voluntary hospital system—one which the medical profession is in danger of losing.

A resident house officer in a voluntary hospital is encouraged in the view that he himself is primarily responsible for his patients. Back of him are a number of senior men—registrars, consultants, etc.—whose function it is to help, advise, and instruct him. If at times his burden becomes unduly heavy their skill and experience are at his disposal to help him carry it. The mental attitude thus engendered serves to keep his keenness at its maximum.

But when he takes up work in a municipal hospital he finds that this state of affairs no longer obtains. His patients are now his in name only. The responsibility for them rests with the superintendent, whose assistant he is. The senior members of the staff, willing though they may be, are not there to be his counsellors. Their primary function is likewise to assist the medical superintendent. The medical officer may even on occasion find to his surprise that certain arrangements he has made with regard to his patient have, without his knowledge, been modified or even countermanded. He becomes conscious of that vague sense of unease which a doctor feels when he is treating someone else's patient.

The effect of this atmosphere is as subtle as it is inevitable. The medical officer finds that his sense of responsibility to himself and to his patient is being gradually replaced by a sense of responsibility to a superior officer to whom he has to surrender much of his initiative. He finds that the stimulus which once came from inside him now comes from outside; and he does his work well not because he wants to but because he must.

Thus the voluntary hospital system contains much of the essence of democracy because it procures for its medical staff the maximum of assistance combined with the minimum of interference and the minimum of coercion.—I am, etc.,

Plymouth, Sept. 8.

M. R. THOMAS, M.D., M.R.C.P.

SIR,—What is the essential difference between the voluntary and municipal hospital systems? Is it something subtle and difficult to define, or is it something readily apparent? That is the question which has been asked by Sir Frederick Menzies (September 6, p. 353). It has been the subject of debate from pre-war time, in fact ever since the rapid growth of the municipal hospital has challenged the voluntary. Sir Frederick Menzies's question will, no doubt, provoke considerable discussion, as was intended. It is indeed time that the relative merits of the two systems were discussed in the open by the profession, for post-war changes will inevitably project a scheme for the unification or co-operation of the two hospital systems.

Briefly here are my observations and conclusions for what they are worth. I have spent the first four years of my post-graduate time in voluntary hospitals of high standing, and I have been resident assistant surgeon in a teaching hospital; since then I have worked in several municipal hospitals in a senior position. I have also been in general practice, so at least I have had first-hand experience.

Although the two hospital systems had different beginnings, the primary function of each is to treat sick poor in the best possible way. The voluntary hospital has a second function—to train and teach the medical personnel. The municipal hospital has no such purpose, nor does it attempt to have or encourage

such a purpose. Here lies the crux of the whole matter, for it has many repercussions. The old-established voluntary hospital system of arranging medical personnel so that the most junior medical man on the staff is responsible to another more experienced, and he, in turn, to a senior man can hardly be bettered. Such an arrangement of personnel achieves the best possible co-operation in the patients' interests, and in addition each junior member benefits from the knowledge and experience of his seniors. This system promotes free communication of enthusiasm and ideas. Such an attitude to medicine is both productive and progressive. Very different is the position of the M.O. in the municipal hospital. He is usually allocated to look after certain wards among other duties, and over these he may have complete charge. Here he can learn only from his own mistakes and experiences, the supervision, if available, being as a rule inadequate. The limitations of this method of learning depend a great deal on the ability of the doctor, but at the best it is unsatisfactory both to him and to his patients. It leads to a process which might be described as "drifting along," in which intellectual arrogance based on a small knowledge not infrequently shows itself. In addition, lack of co-operation in the accessory departments is often a prominent feature. No enthusiasm can possibly arise in such a system, or if it did it would be quickly strangled. It is this lack of willingness to learn and co-operate that renders the municipal hospital sterile. There is, of course, the question of selection of medical personnel. In view of the fact that the posts in voluntary hospitals are essentially apprenticeships, where the best facilities of learning are offered and immediate monetary gain is small, the man attracted as a rule is one whose main aim is to become a better doctor. The better pay, greater comforts, and possibility of permanency associated with the municipal hospital posts tend on the whole to draw a different type of man.

This is but a sketchy outline of the most important influences which in my opinion produce the difference in "atmosphere" between the two hospital systems. There are, of course, many other lesser factors. To mention a few—the off-duty system in the municipal hospital and the mixed nature of duties tend to cause lack of continuity in treatment and therefore indifference or lack of interest. The position of the medical superintendent requires consideration, but a discussion of it is beyond the scope of this already overlong communication. Suffice it to say that it would be an advantage to have a medical committee at which the senior member of each department would sit and some of the consultant staff.

This letter does not seem complete without my briefly putting forward a few suggestions for remedying some of the defects I have criticized in the municipal hospital system. These are:

1. The appointment of highly qualified men who have been trained in voluntary hospitals to the senior posts in the medical, surgical, and gynaecological departments; and that high salaries should be attached to these posts.
2. A team system of arranging medical personnel.
3. Monthly clinical meetings, to which outside doctors serving the district would be invited, to discuss clinical cases of interest; for the encouragement of original papers by members of the staff, and to provide lectures by specialists from other hospitals. Such societies would organize a suitable reference library and provide the important current journals.
4. If possible, arrangements for students to do three-months internships, either in vacation or as part of their clinical training.
5. A scheme for sending senior members of the staff to see other clinics at work in this country and abroad.
6. The avoidance of red tapeism so far as is compatible with the control of the municipal authority, to allow freedom of thought and action in each department. This may seem vague, but it would be impossible to dilate without greatly extending the length of the letter.
7. The provision of first-class laboratory facilities with an enthusiastic pathologist and staff, for this is the hub around which the essential and academic activities of a hospital centre.
8. A full complement of consultant staff.

This résumé may sound Utopian in some respects, but I have had experience within recent times of most of the suggestions made. I arranged, with the co-operation of the medical superintendent, to have six students reside in the hospital during a vacation. A scheme of work in clinics was arranged for them embracing all departments, particularly stressing clinical pathology. The results were most encouraging, justified by enthusiastic students and by the senior members of the resident

staff, who felt much the better for it. There is no doubt that teaching and the critical faculty of the student are the best stimulus for maintaining high clinical standards. This would also put to use the enormous amount of clinical material which has been wasted up to the present time in big municipal hospitals.

The picture I have painted of the municipal hospital may seem black. I am aware there are some in which real efforts are made to prevent the M.O.'s duties becoming just a "job of work," but this is far from being general. I myself believe that the municipal hospitals have a great future, and I am anxious to see them in such a position. It is a new hospital system and still in a transitional stage, but if they are to produce that elusive "atmosphere" enjoyed by the voluntary hospitals, and if they are to become a productive and progressive unit, then they must to some extent introduce the older-established regime in respect to medical personnel.

In conclusion I wish to point out that I have made no attempt to compare the defects and merits of both hospital systems. My object has been to show some of the reasons why the atmosphere in the municipal hospital is different from that in the voluntary, which is the question Sir Frederick Menzies has asked, and some suggestions are made for remedying it.—I am, etc.,

Sept. 10.

D. LANG STEVENSON.

SIR,—In answer to Sir Frederick Menzies's question, "What are the particular virtues of the voluntary hospital system which are conspicuous by their absence in the municipal hospital system?" (September 6, p. 353), the short reply must be: power to reform themselves in the voluntary hospitals. If and when the municipal hospitals need reform it must come from outside or from above and from persons or institutions in the state of relative freedom enjoyed in the voluntary system.

Let me define a voluntary hospital in theory as a living organism in the hospital world, deriving its sustenance from the disinterested efforts of contributors, staffs, and management. It can organize and reform itself from within, which it does by the democratic method of committees of contributors, staff, and governors. Authoritarian systems live on a stock of vitality inherited or plundered from free systems and must perish from lack of inspiration unless continually nourished by the free systems.

Let the voluntary hospitals beware that they do not tamely surrender their lives, or they may find their corpses awaiting resurrection in years to come from the churches, the monasteries, and the village meeting.—I am, etc.,

Edgbaston, Sept. 16.

FAUSET WELSH.

Planning for Mental Health

SIR,—Since perusing the abstract (p. 276) and leader (p. 269) in your issue of August 23, I have studied the report of the B.M.A. Committee on Mental Health, and I feel that some of the facts and figures quoted therein deserve more attention from practitioners and the general public than they have hitherto received.

One of the witnesses examined by the committee considered that 60% of the normal population of this country is psychoneurotic. Millais Culpin and Smith,¹ in an investigation of 1,000 persons actually at work in different occupations, found symptoms which interfered with their output to a greater or less extent in from 40% to 60%. As might be reasonably expected, the physically ill would show a higher proportion of mental unfitness than those who are pursuing their daily vocations. Four American physicians investigating 1,200 routine admissions to a general hospital found psychic factors in 79%, and expressed the opinion that psychotherapy would play a critical part in their recovery.² British observers are commonly regarded as less sensational, but there are some who have made even more startling deductions. Thus, Davies and Wilson³ found 84% of 205 patients with peptic ulcer suffering from psychological tension; and Wittkower⁴ no fewer than 37 out of 40 cases of ulcerative colitis, or 92.5%, presenting definite mental symptoms, which he grouped under the heads of obsessional, hysteric, schizothymic, and depressive. Many other somatic diseases are referred to by the committee as being associated with mental symptoms, and it is, of course, common knowledge at all psychiatric clinics that the reverse of the *mens sana in corpore sano* is undoubtedly true.

The above are among the highest percentages quoted by the committee, but, after sifting a very great deal of variable evidence,

it reaches the conclusion "that in any group of sick persons something like 30% will be found to be suffering from conditions about which it is helpful to have psychiatric advice, and a considerable proportion will be found to be in need of treatment [by a psychotherapist]." In a subsequent paragraph it emphasizes that neither doctors nor patients realize to what a great extent psychiatric treatment may relieve many unhappy and inefficient members of the community. As a natural corollary to these opinions the committee makes this further recommendation: "In view of the large number of patients among the general medical sick, apart from cases of obvious mental disease, who would benefit from psychiatric advice and treatment, every hospital, whether voluntary or municipal, general or special, which has one hundred or more beds, should include on its staff a physician in psychological medicine (or more than one in larger hospitals) whose duties should include regular visits."

Dr. Henry Harris, in his recent letter (September 13, p. 386), divides humanity into those who are chronically neurotic, psychotic, or defective, and those (the vast majority of us) who, at some time or another, have had or will have nervous complaints or temporary maladjustments. After describing what he means by the latter group, he adds, "All these are minor problems when they first arise, but the physician who fails to make a distinction between those who are permanently ill and those mentally perplexed may fail to treat the latter. Problems which might easily be solved or prevented by one or two interviews may graduate into chronic and permanent illness." He asks why there should be such discrepancies in the evidence received by the committee on the incidence of psychopathic disease, but the committee has already summed the matter up in a very few words: "The number of patients sent to hospitals is a measure not of the incidence of mental disease but of the extent to which it is recognized by general practitioners."

How far practitioners differ in their attitude towards the psychoneuroses encountered among their patients, whether complicated by physical disease or not, can be seen by further reference to the report of the committee. The Tavistock Clinic was able to treat 279 patients out of the 1,914 who applied for treatment three years ago. The doctors who sent those couple of thousand patients to the clinic stated that they would have sent four times as many if facilities for treatment had been available. On the other hand, there are physicians who maintain that they have never referred a single patient to a psychotherapist or to a psychiatric clinic. In fairness it must be admitted that many are unable to avail themselves of the services of a specialist, since there is no clinic in their neighbourhood. The map opposite page 16 of the committee's report shows vast areas of the United Kingdom devoid of such resources. Others prefer to treat their patients, *secundum artem*, with bromide bottle or sedative pill, and if they genuinely believe that is the best treatment for the psychoneurotic their views are worthy of all the respect due to tradition and practice over many centuries.

But there is still another group to whom you refer in your editorial, Mr. Editor—those who regard us with a good deal of suspicion and prejudice! They must form a large group, if you consider that they are able to discourage a potential psychotherapist from embarking on a psychiatric career. Can nothing be done to convert them from their intransigent attitude towards a form of treatment which strives only to reach the same goal as the practitioner—the welfare of his patient? The committee has devised a practical and workable scheme for the rehabilitation of the mentally unfit; but to obtain its full measure of success it will require not merely a large number of trained psychotherapists, but also the support and co-operation of the entire medical profession, and in particular the general practitioner.—I am, etc..

C. LODGE PATCH,
Lieut.-Colonel, I.M.S. (ret.).

Shrewsbury, Sept. 17.

Future of Medical Education

SIR.—As a biologist I should like to be allowed to comment on the two very interesting articles on the future of medical education (September 6, pp. 323 and 327). It is very encouraging to read that such an eminent authority as Prof. J. A. Ryle thinks so

highly of the value of biology as the foundation of the medical student's work. We biologists have, of course, always been of this opinion, but I believe that in the past this view has not been so strongly held by some medical men.

From my experience as a teacher and as an examiner for the First M.B., I am convinced that Prof. Ryle is right when he states that the student should not enter on his medical course till he is 17, for I have found that students younger than that make little progress until they are more mature. These young students, even if they have matriculated, would do far better continuing at school and completing their general education, concentrating especially on those subjects which they are likely to drop when they begin their First M.B. course. I believe that too many students begin chemistry and physics too early at school, with the result that they go over the same stuff again and again without any profit to themselves. Except in the very elementary form of general science, these subjects can well be left until later, and the time might be more profitably devoted to arts subjects, so that when the student begins his pre-medical work he has a background of general knowledge and can express himself simply and clearly in English. This time might also be partly spent in the study of foreign languages such as French and German, which are much easier to learn at that age than later. If students were to concentrate on these cultural subjects at school, we might avoid what is now a common experience of many examiners, who find that the powers of expression by medical and other students are often crude. Far too few have any idea of the proper use of our language.

Biology may well be taught during the school period, but I am of the opinion that the schools might be well advised to leave the First M.B. teaching to the universities and medical schools, where facilities for such teaching are better and the course can be covered in a year. School biology should be of a much more general type, less anatomical and with the emphasis on the modes of life and habits of animals and plants. This can be done especially well in schools, particularly by those in the country, where there are greater opportunities for field work and the training thereby of the powers of observation. In other words, the work is more of the type that used to be called "natural history." It is at this stage that the student can obtain the sound knowledge of oecology such as is desired by Mr. Donald McDonald, leaving the comparative anatomy and more detailed biology to the First M.B. course. I do not think that Mr. McDonald's suggestion that the comparative anatomy should be studied simultaneously with human anatomy is either practicable or desirable. Surely the generalized comparative anatomy is the introduction to the pure human anatomy, as the elementary physiology taught in the biology course is the foundation of the later human physiology.

Mr. McDonald's proposal to include such things as human heredity in the First M.B. course would overload it, especially as the student would not at that stage be in the position to realize its importance and significance. Most medical schools and universities have biologists on their staffs; why could they not be used to give a few lectures on some of the more advanced applications of biology to students who have gone some way on their clinical work?—I am, etc..

C. C. HENTSCHILL, M.Sc.,
Senior Lecturer in Zoology

Chelsea Polytechnic, Sept. 15

Communal Feeding in Schools

SIR.—Apparently Dr. Letitia Fairfield (September 6, p. 359) is very angry with me, but I hope she won't allow her wrath to obscure her judgment or close her mind to realities.

Despite her letter I still think compulsory and universal school dinners the best means available and the most economical for ensuring satisfactory nutrition in our school children. There is no doubt that they can be provided more cheaply than a similar meal at home and at a cost within the means of most parents, so why Dr. Fairfield thinks they should appreciably increase the taxpayer's burden I don't know, for necessitous cases form only a small percentage of the whole, and teaching cookery is already a charge on the cost of education. Certainly family allowances which she seems to favour, will cost the taxpayer far more, and then he will have no guarantee that the money will be spent on the children. From my own experience I can say that the children in most need of it are least likely to get it.

It is nonsense to pretend that the success of the public school system depends on the social background of its pupils and makes all the difference between the actual and feared results of communal feeding. If the public schools are closed after the war it will be because of financial stringency and not because of psychological or other defects. As to their dysgenic effects on the nation, of course the cost of educating children at public schools must limit their production. However, if the nation wants more children it will have to pay for them, and not only for those who go to public schools. But a high birth rate does not seem the remedy for widespread unemployment and frequent wars, and until these are cured by other means parents will be prudent in their production of babies.

Dr. D. W. Winnicott (p. 358) admits that "voluntary communal feeding of children can be successful, not only physically but also in regard to emotional development." Why he thinks the results should be worse if made compulsory and permanent is not easy to see. Perhaps it is one of those "things in heaven and earth not dreamt of in my philosophy." But let me assure him that I am not indifferent to "complications arising out of feelings, fantasies, and superstitions," though I beg leave to doubt that any serious complications of this nature need be feared from school dinners. I have seen no sign of them at our own school dinners. In fact, our backward and "difficult" children have shown marked improvement mentally as well as physically after a course of school dinners. A little mental as well as physical buffeting is good for children by helping to prepare them for the much greater stress and strain they will have to face when earning their own living.

Undoubtedly a small percentage of the children evacuated have suffered serious emotional upset from evacuation to strange homes and strange people, but they form a surprisingly small part of the total. In any case, emotional disturbance arising from evacuation cannot be compared with any slight upset which might arise from compulsory attendance at school dinners, though why this should cause any more mental trauma than compulsory attendance at school for lessons is not clear. Furthermore, exceptional children could be excused, but they should not be allowed to stand in the way of a provision which would benefit the majority.

To sum up: 11% of our school children are obviously undernourished. How many are suffering from deficient diets we don't know, but Sir John Orr's National Survey published in 1936 suggests that roughly half the population subsist on diets which are deficient in some or all important constituents. Compulsory school dinners appear to be the only satisfactory solution of the nutrition problem in sight. No homes need be burnt down to provide them, and maternal relief is more likely than maternal depression.

But fancy all this ado and dark foreboding over an hour longer in school and a meal less at home. It makes one wonder how much of it is prompted by genuine anxiety for the welfare of the mothers and their children.—I am, etc.,

Gosport, Sept. 8.

G. W. FLEMING.

A Simple Technique of Intravenous Infusion

SIR.—The following modified method of fixing a cannula in a vein for the purpose of infusion or transfusion has been found successful, and it seems worth while making a brief note of the technique, as the call for intravenous infusion is such a frequent happening in these days.

After cleaning and anaesthetizing the skin, a small oblique incision is made over the vein instead of the usual transverse one. Exposure of the vein is effected by the beak of a haemostat in the usual way. A careful dissection of the vein from its surrounding fascia is unnecessary. A curved cutting needle is threaded with a strand of silkworm gut and is now passed through one skin edge, beneath the vein and out through the outer skin edge. The ends of the suture are caught in a haemostat and traction is exerted in order to obstruct the venous flow. With a pair of sharp-pointed scissors a small longitudinal nick is made opposite the silkworm suture in the anterior vein wall and the cannula quickly inserted. The suture is tied round the vein and cannula. The suture now fulfils three functions: it occludes the vein, it keeps the cannula in position, and it closes the skin incision.

After conclusion of the infusion the suture is cut, the cannula quickly withdrawn, and a new skin suture inserted to close the wound, which is covered with a sterile dressing and bandage. As a prophylactic measure against sepsis sulphanilamide powder should be rubbed into the wound before tying the suture. The longitudinal cut in the vein will heal, and, as the vein is not ligatured, the circulation has a good chance to become re-established and the vein could be used again at a later date.

It will be seen from this brief description that this technique economizes in movements, time, and material, a single strand of silkworm gut being the only suture necessary. The whole procedure takes little more than a minute to perform. It is in these respects that this method has certain advantages over those mentioned in textbooks.

I wish to thank Mr. D. Lang Stevenson, F.R.C.S., for his help in trying out this method.—I am, etc.,

Romford, Essex, Sept. 4.

E. FRANKEL.

"Perfect Sight without Glasses"

SIR.—As you rightly point out in your annotation on this subject (September 13, p. 383), the whole treatment of defective sight by exercises is based on fallacy. The answer to Dr. J. Parness's inquiry (p. 389) is, therefore, as follows: No degree of ametropia is cured by the exercises of Bates or any of his brethren, and those who seek this treatment hoping to give up glasses which they genuinely need will be disappointed.

However, in this country the majority of the population buy their glasses from "practitioners" who have no medical knowledge, and it follows that there are thousands of us who are wearing glasses unnecessarily. If one such should fall into the hands of a Bates practitioner, a "cure" will result, but it should not be necessary to go to a second unqualified practitioner to be told that the glasses provided by the first were unnecessary from the start.

If the Bates treatment is given to a person who genuinely needs glasses, then at the worst he is a sadder, wiser, and poorer man. But where it is given to patients whose headache or defective vision is due to general causes—perhaps renal or intracranial—then the delay caused by the treatment may well have a disastrous result. If only for this reason it seems a pity that Dr. Huxley should have given it a free advertisement.—I am, etc.,

London, W.1, Sept. 15

SEYMOUR PHILPS, F.R.C.S.

SIR.—Benjamin's book is, of course, complete nonsense, but it appeals to the belief in magic latent in so many apparently modern rational people. As only those with no useful work to do in the world have time to devote to this particular magic, not much is lost to society if such persons do leave off their reading-glasses. If myopic they will still see to read, and so can discuss their magic "cure" in complete honesty of belief.

The world's workers will continue to use glasses when necessary to get on with their job with the least possible strain. Glasses do not, of course, cure hypermetropia, myopia, or astigmatism. They simply relieve the strain involved in trying to concentrate on close work with eyes which are out of focus.

The only people to whom Benjamin's otherwise comic book could do any harm, if its advice is followed, are those suffering from glaucoma, iritis, and corneal ulcers, in which cases failure to recognize and treat the disease properly leads inevitably to serious loss of vision or blindness. In this the book is on a par with many other systems of quack cures—e.g., a fairly well-known system of "curing" cataract without operation. This system labels all its clients as cases of cataract, and "treats" chronic glaucoma, retinal haemorrhages, etc., with complete impartiality by means of enormously strong convex glasses, by the aid of which the victim is encouraged to read for so many hours a day. As a further aid the lenses are tinted a most convincing green. How, then, can they fail to "cure"? I imagine that this system does much more positive harm than Benjamin's book.

I have known numbers of patients who have tried to follow Benjamin's precepts, but have yet to encounter a single "cure." They all relapse and go back to their glasses. I lent the book some years ago to a man with slowly progressive cataract. He

dreaded the thought of operation, and for two years he faithfully carried out the whole rigmarole of exercises, dieting, etc., advised by Benjamin. He lost a lot of surplus fat, but his cataracts progressed as steadily as the waves climbed the shore on which King Canute sat of old, till finally he had to be led about by his wife. Now he is in the Home Guard; alas! not thanks to Benjamin's magic, but to "orthodox medical science," in accordance with which he got 6/6 vision (with glasses) after the crude method of surgical extraction of first one and then the other cataract. His temper, which had steadily worsened under Benjamin's treatment, has also improved, until now his wife says he is quite human again. For one of his temperament Benjamin supplied quite a useful occupation until it was time to operate.

Like all its predecessors, Benjamin's book will fade out in time, to be replaced by other "latest discoveries" in magic cures. An infallible rejuvenator of sclerosed arteries began life as a lotion guaranteed to grow a thick thatch on the baldest scalp.

We affect to despise the ignorant belief of the African native in his witch doctor, and yet how many people read and believe their favourite astrologer in one or other of the Sunday papers?—I am, etc.,

Bournemouth, Sept. 14.

DAVID HARDIE.

The Spread of Poliomyelitis

SIR.—In an annotation in your issue of August 30 (p. 311) you refer to the findings of Burnet and Jackson that after oral infection in *Macacus irus* "the mesenteric lymph nodes almost always contain the virus in such large amounts . . ." In this connexion the work of Burrows (*Arch. intern. Med.*, 1931, 48, 33) is of interest. Burrows investigated the pathology of poliomyelitis in 50 fatal cases, concluding that the nervous involvement was only a rare complication in a widespread infectious disease, and that the name "infantile paralysis" was misleading, since it described what was only an occasional complication. He suggested that the name "acute lymphatic hyperplasia" would accord better with the pathological findings.

In experiments by Yoffey and Sullivan (*J. exp. Med.*, 1939, 69, 133) attention was drawn to the part played by lymph nodes in the diffusion of vaccinia virus in rabbits. Virus from a primary nasopharyngeal focus of infection reaches the regional lymph nodes and multiplies there (cf. McMaster and Kidd, *J. exp. Med.*, 1937, 66, 73). But it does not remain confined to these nodes, for we were able to show that a constant stream of virus leaves in the efferent lymph and enters the blood. Furthermore, the mechanism by which virus leaves the node so readily appears to be very simple. The virus becomes fixed by the lymphocytes, and it is these lymphocytes, normally leaving the node in large numbers, which convey virus to the blood stream. Once in the blood, virus-containing lymphocytes would appear to be able to leave the blood capillaries in any part of the body, including the central nervous system.

If this mode of spread held good for the virus of poliomyelitis also, it would afford a simple and attractive explanation of the way in which virus could reach the central nervous system from infected mesenteric lymph nodes. However, in actual experiments with *Macaca mulatta* we (Yoffey and Drinker, *J. exp. Med.*, 1939, 70, 83) were unable to find poliomyelitis virus in cervical lymph after nasal instillation of virus which did ultimately reach the central nervous system and give rise to paralysis. Furthermore, the disease could not be produced by injecting the virus into lymph nodes. It was felt that a virus which was very specifically neurotropic would not perhaps flourish in lymph nodes, and the conclusion was drawn that "the strain of virus employed does not spread by way of the lymphatic vessels and nodes." Burnet and Jackson's finding of virus in mesenteric lymph nodes so frequently and in such large amounts suggests that this conclusion may not be true for other possibly less specifically neurotropic strains of virus, and that our experiments may be well worth while repeating with such strains.—I am, etc.,

J. M. YOFFEY.

Department of Anatomy, University of Bristol, Sept. 17.

Ship Surgeons and Doctors on Military Transports

SIR.—A copy of the *Journal* of June 14 came my way recently at a certain port of call, and I can thoroughly endorse the views expressed by Dr. James Prendergast on page 904 regarding the

position of ship surgeons and their relations with the medical personnel on H.M. transports. Speaking with experience in both connexions during the war of 1914-18, as well as this, it grieves me that the R.A.M.C. especially still plays the old game of putting square pegs in round holes, and there is still now in 1941 the same occasional friction that was so noticeable twenty-five years or so ago. King's Regulations so far as troopships are concerned require revision. For instance, the title S.M.O. makes an invidious distinction and, as so frequently happens, the position is given to a junior officer whose only claim to seniority lies in the fact that his subordinates joined up, it may well be, only a matter of a week or two after he did. In my last ship, for example, the senior medical officer of the two appointed to that vessel was a lad of 26 who had had no previous experience to speak of either at sea or on shore, whereas his junior had had seven years' experience, partly as a ship surgeon, but mostly as a resident medical officer of a fairly large municipal hospital, to his credit, but had not been gazetted till a fortnight after the other. I will say this for the junior, that he was loyal to himself, and that his young senior was wise enough to rely in great measure upon his more proficient colleague. But it does not always work out so by any means. They were busy enough when there were troops on board, but were completely at a loose end when, as so often happened, the ship was empty. This was simply waste of material. On one recent voyage from North India to the Levant, when this S.M.O. was left behind because of illness and the junior automatically became S.M.O. and there were also seven or eight I.M.S. officers, including a major, it was I, the crew's doctor, who was called upon to make an exhaustive analysis of the ship's drinking-water. Before complying I notified the ship's commander that a complaint had been made and obtained his ready assent. Incidentally, the O.C. Troops knew nothing of the affair until it was over and done with. That, however, was not my pigeon.

During the last war on one voyage when I was temporarily in the R.A.M.C. I had charge of some 1,500 prisoners of war. I was called upon for six weeks to act as ship surgeon as well. On another occasion, when a free lance, I was ship surgeon on a transport ferrying American troops across the Atlantic; I had the whole ship to look after what time the U.S.A. doctors were all down and out. True it was only for three days, but I had my hands full.

Finally I may say that in a pretty lengthy experience I have never had the faintest difficulty with officers of the R.N. or the R.A.F., and that it is the ship surgeon's own fault if he permits himself to be overridden, especially by the macrocephalic type one encounters from time to time. When there is real danger, little differences vanish.—I am, etc.,

Aug. 15.

ATHELSTANE NORRIS, M.D.

Air-raid Noises in Psychotherapy

SIR.—The classical allusion in my letter of August 16 (p. 243) has evidently put Dr. J. H. Mellotte off the point of my criticism and led him (September 6, p. 354) into a very fallacious mode of reasoning. I have no doubt that, as he claims, the intentions of the authors of the criticized article, Majors McLaughlin and Millar, were excellent and that their aim was to conserve available man-power. But good intentions, it should be obvious, are not enough to excuse a particular form of therapy. Otherwise they would justify osteopathy, nature cures, Christian Science, and every other type of treatment that professed the same aims.

To put forward, as Majors McLaughlin and Millar did, "oversensitiveness" to noises as an explanation of a psychological disorder, and "conditioning" by gramophone records as the appropriate treatment, is surely impressive as a conception far short of the scientific attitude. It is equivalent to "explaining" claustrophobia as an oversensitiveness to closed spaces and treating the patient by conditioning him to progressively smaller rooms. The marks of regression are visible upon the whole procedure, but it may be that Dr. Mellotte will be able to lick it up with his use of "parergastic" as a serious contribution to psychotherapy. "Parergastic"! What a horror of a word, any words that could validly be applied to his line of argument, in Anglo-Saxon, not in Meyerian terminology.—I am, etc.,

FREDERICK DUFFY.

London, W.1, Sept. 12.

Obituary

DAVID R. ROWLANDS, M.D., F.R.C.S.Ed.

Consulting Physician, Birmingham and Midland Skin Hospital

We regret to announce the sudden death on August 28 at his home at West Kirby of Dr. David R. Rowlands. A distinguished skin specialist, he had been associated with the Birmingham and Midland Skin Hospital for forty years.

David Richard Rowlands, born at Oswestry in 1871, was the son of a veterinary surgeon. He began his studies in 1891 at Edinburgh University, where he had a brilliant record as a student, being thrice a medallist during his course. He graduated M.B., Ch.B. with honours in 1896 and later became demonstrator of anatomy, gaining his F.R.C.S.Ed. in 1899. On completing his studies, Dr. Rowlands went to Swansea Hospital as house-surgeon and later as house-physician. When he left the hospital he prepared his thesis for the M.D., his subject being ectopic gestation. On setting up in Five Ways, Birmingham, he met with instant success as a general practitioner, and in 1901 he joined the staff of the Birmingham and Midland Skin Hospital as clinical assistant. Later he became senior honorary physician and held that post until 1936, when he reached the age limit. He was then appointed consulting physician, and a few months later the board of management marked his long association with the hospital by presenting him with a silver salver and his portrait in oils. The portrait now hangs permanently in the board room. Dr. Rowlands made valuable contributions to the methods of combating occupational dermatitis and was associated with the provision and development of many special facilities at the hospital for combating skin diseases. He insisted on the need for an enlarged hospital; and it was a fitting tribute to his many years of service that in 1935 the in-patient hospital in Edgbaston was opened, followed by a remodelling of the original hospital for the use of out-patients.

About ten years ago he went to live at Oswestry (retaining his Birmingham practice), and latterly he removed to West Kirby, where patients still sought him, and he was unable to enjoy a full retirement. He was a Fellow of the Royal Society of Medicine, a member of the British Medical Association for forty-one years, and of the Midland Medical Society; and after his many lectures to the St. John Ambulance Association was appointed an honorary life member.

Dr. WILLIAM ROBERTSON, who retired from the post of medical officer of health for Edinburgh in 1930, died on September 7. A native of Leith, he studied medicine at Glasgow University and the Anderson College, graduating M.B., C.M. in 1887 and proceeding to the M.D. in 1891. He obtained the D.P.H. of the Royal Faculty of Physicians and Surgeons of Glasgow in 1893, and the F.R.C.P.Ed. in 1923. Before his appointment as head of the health administration of Edinburgh in 1923 he had been M.O.H. at Perth and at Paisley; he was appointed M.O.H. for Leith in 1904, and continued in office there after the amalgamation of the port with Edinburgh. At Paisley he organized the water department with much success, and at Leith he was energetic in combating outbreaks of small-pox and of plague, for which he received public thanks from the Scottish Board of Health. In Edinburgh, where he had lectured for some years on public health at the Royal Colleges of Physicians and Surgeons, he was responsible for the very popular health exhibitions in Waverley Market, and thus brought before the eyes of thousands of citizens the value of personal and public hygiene and the range of civic effort in the department which he administered. Dr. Robertson was the author of *Sanitary Law and Practice* for students reading for the D.P.H., and of handbooks on meat and food inspection and on practical first aid.

News reaches this country of the death of Dr. ALEXANDER WILLIAM FORRESTER, late medical officer of health for Bulawayo. A student of the Royal College of Surgeons in Ireland and the Carmichael College, Dublin, he took the Scottish triple qualifica-

tion in 1893 and the D.P.H. later. He went out to Rhodesia in 1897, and had been there long enough to know everyone in the Colony. He served throughout the last war as medical officer of a Rhodesian native regiment with the rank of major, and received the French Croix de Guerre with palms and was mentioned in dispatches. After the end of the war he was Government medical officer and M.O.H. for Bulawayo, retiring in 1930. At the beginning of this war Dr. Forrester offered his services to the Colony, and despite his age—a few months short of 70—he was appointed medical officer to No. 2 Training Centre. He had been a member of the British Medical Association since 1904, was joint honorary secretary of the Rhodesian Branch, 1922-6, and honorary secretary of the Bulawayo Division 1922-5. One of his friends writes: "In common with thousands of other Rhodesians I have lost a real comrade by the death of Major A. W. Forrester. He was too much a lover of humanity in general to be an outstanding 'parade-ground soldier,' but as a kind, sympathetic, and understanding medical officer he excelled, and his friendly smile and the merry twinkle in his eye were in themselves a tonic to his patients when he appeared in the wards. He was universally loved by all who knew him, young and old, European and native, patients and colleagues. He was certainly 'the youngest old man' in Rhodesia, for apart from his years he was by no means an old man, and if anybody in Rhodesia was entitled to be called 'everybody's friend' it was Major Forrester. His death leaves a vacancy in the whole of Rhodesia which will probably never be filled. Major Forrester, his wife (who predeceased him by only a few weeks), and their only son—Harding Forrester, the Rhodesian novelist—were a particularly devoted family, popular everywhere."

We regret to announce the death of Dr. CHARLES E. P. FORSYTH, who practised in recent years as a physician at Newport, Monmouthshire, after his return from India. He studied medicine at Aberdeen University, graduating M.B., Ch.B. in 1899, and took the M.R.C.P.Lond. in 1903 and the D.P.H. of Liverpool in 1909. Dr. Forsyth's early appointments were those of assistant medical officer in the Fever Hospital Service of the Metropolitan Asylums Board, house-physician and senior resident officer at the Bradford Royal Infirmary, and pathologist in the research laboratories of the Liverpool Hospital for Consumption. He joined the British Medical Association immediately after graduating and took an active part in the local work of the Association during his time in India. He served as honorary secretary of the Assam Valley Division 1923-5, and had been honorary secretary and president of the Assam Branch, representing it at the Annual Meetings of 1924 at Bradford and 1925 at Bath. At Newport Dr. Forsyth was appointed honorary physician and physician in charge of out-patients to the Royal Gwent Hospital and consulting physician to the Newport Mental Hospital, and held the post of medical referee to a number of assurance companies. He was the author of several papers in the *Indian Medical Gazette* and in the *Proceedings of the Assam Branch of the B.M.A.*

The following well-known medical men have died abroad: Dr. WILLIS COHOON CAMPBELL, professor of orthopaedic surgery, University of Tennessee College of Medicine, and author of several works on orthopaedics, aged 60; Dr. FRANK CLINCH HAMMOND, who was appointed in 1925 editor of the *Atlantic Medical Journal*, predecessor of the *Pennsylvania Medical Journal*, aged 66; and Dr. THOMAS A. WOODRUFF, past-president of the Chicago Ophthalmological Society and author of *Common Diseases of the Eye*, aged 75.

There is evidence to show that the consumption of flour is rising, but it is possible that the extra quantities are being used for cakes and biscuits, which are greatly in demand in industrial areas, rather than for bread itself. A bulletin issued by the Children's Nutrition Council advocates that in any case the additional flour consumed should be of the wheatmeal variety, and also that biscuits, slab cakes, and confectionery should be reduced to a small number of simple varieties and rationed on the "group" basis, with priority for war workers and heavy manual labourers (and perhaps also for persons between 12 and 18). A start has already been made in reducing the varieties of chocolate and sugar confectionery.

The Services

HONORARY PHYSICIAN TO THE KING

Majör-General P. S. Tomlinson, C.B., D.S.O., late R.A.M.C., has been appointed Honorary Physician to the King in succession to Major-General R. W. D. Leslie, C.B., O.B.E., late R.A.M.C., who has retired.

R.N.V.R. OFFICERS' DECORATION

The King has awarded the Royal Naval Volunteer Reserve Officers' Decoration to Surgeon Commanders Thomas Weir Drummond, Harold Oliver Martin, and Hugh Edwin Hall, R.N.V.R.

AIR FORCE AWARD

The George Medal has been awarded to Group Captain J. A. Gray, D.F.C., and to Acting Squadron Leader Joseph Aidan MacCarthy, M.B. The announcement in the *London Gazette* of September 9 reads as follows:

"One night in May, 1941, the pilot of an aircraft attempted to land with the undercarriage retracted. The aircraft crashed into the main bomb dump and then burst into flames. Group Captain Gray and Squadron Leader MacCarthy immediately went to the scene of the accident. Although there was some delay in getting the fire tender to the spot, owing to wire entanglements at the bomb dump, Group Captain Gray and Squadron Leader MacCarthy entered the burning aircraft and between them succeeded in extricating two members of the crew who were trapped. By the time the first man had been extricated the fire had spread from the starboard tanks to the cabin and on to the port tanks. Ammunition, incendiaries, and flares were burning in the wreckage, whilst numerous explosions erupted from the tanks. In spite of this an attempt was made to rescue the pilot, who was still trapped at the bottom of the fuselage. He was dragged clear, but his harness still held him to the burning aircraft. Before he could be released another petrol tank burst and flames spread to such an extent that any further attempts to rescue him became impossible. Group Captain Gray and Squadron Leader MacCarthy were assisted by two other officers, who both displayed great courage in their efforts. Group Captain Gray received severe burns on his head and his uniform was destroyed, but he continued his efforts until overcome by the fumes. Squadron Leader MacCarthy suffered minor facial injuries caused by burns but, despite this and the strain to which he had been exposed, he would not retire to his quarters until he was satisfied that everything possible had been done for the comfort of the injured. Both Group Captain Gray and Squadron Leader MacCarthy displayed great bravery in the most appalling circumstances."

CASUALTIES IN THE MEDICAL SERVICES

ROYAL NAVY

Surgeon Commander ROBERT WALLACE NESBITT, R.N., lost his life on active service this month. He was the son of the late Mr. Alexander Nesbitt of Dalkey, Co. Dublin, and was educated at the University of Dublin, where he qualified L.M., L.Ch. in 1918. Five years later he took the degrees of M.B., B.Ch., B.A.O. of the University, and in 1928 obtained the F.R.C.P.I. He entered the Royal Navy as surgeon lieutenant in 1921, was promoted to surgeon lieutenant-commander in 1924, and to surgeon commander six years later. He had been a member of the British Medical Association since 1928.

ROYAL ARMY MEDICAL CORPS

The name of War Substantive Captain SAMUEL BERNARD GREENBERG is included as "Died" in an Army Council casualty list published on September 18. He was educated in South Africa and took the degrees of M.B., B.Ch. of the University of the Witwatersrand, Johannesburg, in 1930. He was house-surgeon and house-physician at Johannesburg General Hospital, and in 1931 became assistant medical officer at the Springs Mines in the Transvaal. He came to this country in 1935, and in the following year settled in practice in Bath. Soon after the war began he was granted an emergency commission as lieutenant in the R.A.M.C. and was promoted to captain last year. He had been a member of the British Medical Association since 1929.

Lieut. RICHARD MENNIE, who died on September 13, was the only son of Mr. James Mennie, J.P., and Mrs. Mennie of Golspie, Sutherlandshire. He was educated at the University of Edinburgh, where he graduated M.B., Ch.B. in 1927, proceeding M.D. five years later. He had held appointments at the Liverpool Heart Hospital and Chester City Hospital and for a time was in practice at Bradford and later at Liverpool. He was granted an emergency commission as lieutenant in the R.A.M.C. about a year ago.

Prisoners of War

Temporary Major David Livingstone Charters.
Captain James Edward Scott Carmichael.
Captain John Emmerson Gray.
War Substantive Captain Thomas Ion Victor Ferguson.
War Substantive Captain Francis Laurence Gerard Malone.

SOUTH AFRICAN MEDICAL CORPS

Dr. WILLIAM NEIL CAMPBELL, who has died while on active service with the South African Medical Corps in the Middle East, received his medical education at the University of Edinburgh, where he was a member of the rugby XV, and graduated M.B., Ch.B. in 1927, proceeding M.D. in 1939. He was elected a Member of the Royal College of Physicians of Edinburgh in 1935. Dr. Campbell acted as house-physician at Edinburgh Royal Infirmary in 1927-8, before returning to Durban, where he became honorary physician to the King Edward Hospital in 1937. He had been a member of the British Medical Association since 1927.

DEATHS IN THE SERVICES

Major-General JOHN MACFARLANE SLOAN, C.B., C.M.G., D.S.O., late R.A.M.C., died at Ifield on September 10, aged 69. He was born on July 22, 1872, the son of Samuel Sloan, M.D., and was educated at the University of Glasgow, where he graduated M.B., Ch.B. in 1898. Entering the R.A.M.C. as lieutenant in 1899, he became major in 1910, received a brevet as lieutenant-colonel in 1915, and was promoted to colonel in 1923 and major-general in 1926, retiring in 1929. He served as adjutant to the Territorial Army from 1908 to 1911. He served throughout the South African War of 1899-1902, when he took part in the defence of Ladysmith, in operations in Natal, the Transvaal, and the Orange Free State, was mentioned in dispatches in 1902, and received the Queen's medal with four clasps and the King's medal with two clasps, and the D.S.O. In the war of 1914-18 he served as A.D.M.S. of Indian Expeditionary Force D in 1916-17, and as D.D.M.S. of the Third Indian Army Corps in Iraq in 1917-19, was mentioned in dispatches six times, and received the C.M.G. In 1927 he was made a C.B. He leaves a widow. At the funeral at Crawley on September 13 the Director-General, Army Medical Services, was represented by Brigadier M. J. Williamson.

Universities and Colleges

UNIVERSITY OF DURHAM

Frederick John Nattrass, M.D., F.R.C.P., has been appointed to the Chair of Medicine tenable at the Medical School, King's College, Newcastle-upon-Tyne, from October 1.

UNIVERSITY OF LEEDS

The following candidates have been approved at the examinations indicated:

M.D.—L. A. Westwood.

FINAL M.B., Ch.B.—Part II: A. M. Bowler, S. Keidan, Bertha Klempman, E. O. Lawton, J. Lees, D. Levi, J. Lyons, Kathleen M. Packett, C. Reichman, B. Sidman, G. H. Templeman, Jean M. Terry, Thomas, D. Velinsky, L. Walsh, J. L. C. Ward, A. Wertheimer.

The West Riding Panel Practitioners' Prize has been awarded to D. L. Richardson.

The medical officer of health for Bury, in submitting his annual report for the year 1940, points out that the estimated population of the borough for that year was four or five thousand less than it had been since 1919, and that this fact would tend to raise such figures as the birth and death rates, and tuberculosis and cancer death rates. In spite of this the tuberculosis death rate was the lowest ever recorded in the borough, being 0.42 per 1,000 population; the cancer death rate, in contrast, was 2.3 per 1,000, the highest so far recorded. Only one maternal death was recorded during the year, the rate being 1.32 per 1,000 total births, a low figure when compared with the general death rate of 17.54 per 1,000 population. This good result may be attributed to the excellent attendance at the ante-natal clinics. At the time of writing the report 3,061 children had been immunized against diphtheria, and as a result only 13 cases were notified in 1940, and there was only one death.

No. 36

INFECTIOUS DISEASES AND VITAL STATISTICS

EPIDEMIOLOGICAL NOTES

Discussion of the Table

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended September 6.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included), (b) London (administrative county), (c) Scotland, (d) Eire, (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths reported under each infectious disease, are for: (a) The 126 great towns in England and Wales (London included), (b) London (administrative county), (c) The 13 principal towns in Eire, (d) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

* Includes paratyphoid A and B for Eire and Northern Ireland.

† Includes primary form in figures for England and Wales, London (administrative county), and Northern Ireland.

‡ Cases of pneumonia not otherwise notifiable.

§ Owing to evacuation schemes and other movements of population birth and death rates for Northern Ireland are no longer available.

A further fall in the notifications of measles in England and Wales occurred during the week. The decrease of 168 cases, compared with the total of the previous week, is the smallest decline in the incidence of this disease during the past ten weeks. The number of cases of whooping-cough in England and Wales was 144 fewer than in the preceding week, but a relatively large rise was recorded in Scotland. The city of Glasgow contributed 159 of the 185 notifications. The incidence of diphtheria showed a slight increase in both countries for the fourth consecutive week.

A further 15 cases were reported from the outbreak of dysentery in Bristol C.B., and this area accounted for approximately one-quarter of the cases in the country.

During the week reviewed 128 cases of cerebrospinal fever were notified in England and Wales, an increase of 30% on the total of the preceding week. The increase was due to the general rise in the incidence of the disease experienced by the northern counties and Wales.

Typhoid and Paratyphoid

The outbreak of paratyphoid fever in Bristol C.B. contributed a further 48 cases during the week, making a total of 170 cases during the three weeks August 17 to September 6. The cities of Liverpool, 20 cases, and Birmingham, 8 cases, were the only other areas in the country with a relatively large number of cases of paratyphoid. A third of the total cases of typhoid in England and Wales was recorded in London, 15.

Poliomyelitis

After poliomyelitis had fallen from 30 to 23 cases a week during the preceding four weeks a relatively large increase of 6 cases was recorded. The notifications of poliomyelitis (29) were widely distributed, involving twenty counties. The largest number reported from any registration area in England and Wales was 2. These areas were: Berkshire, Maidenhead M.B.; Buckinghamshire, Aylesbury M.B.; Dorset, Wimborne and Cranborne R.D.; Lincolnshire, Lincoln C.B. Three of the 6 cases reported in Scotland were notified in Glasgow. Both of the cases in Eire were recorded in the rural district of Ruthdown, Co. Wicklow.

Medical News

A meeting of the Society of Public Analysts and Other Analytical Chemists will be held at the Chemical Society's Rooms, Burlington House, Piccadilly, W., on Wednesday, October 1, at 3.45 p.m., when papers will be presented on "The Determination of Traces of Mustard Gas in Contaminated Foodstuffs and Other Commodities" by H. C. Lockwood, Ph.D., and "A Rapid Method for the Determination of Terpinyl Acetate and Other Esters" by Miss H. M. Perry, M.Sc., and T. F. West, Ph.D. Several chemists interested in war gas detection will exhibit pieces of apparatus which may be of use in micro-analysis.

At the Central Middlesex County Hospital, Acton Lane, N.W.10, on Thursday, October 9, at 3 p.m., Dr. W. Pagel will give a demonstration (lantern slides) of some cases observed in the pathological department of the hospital, 1939-41.

The issue of the *Edinburgh Medical Journal* for September (Oliver and Boyd, 4s.) is a special education number. It opens with a short paper on the future of postgraduate teaching by Dr. James K. Slater, and the last twenty-eight pages are devoted to medical education in Scotland, with particulars of the medical curriculum at the Universities of Edinburgh, Glasgow, Aberdeen, and St. Andrews, and the qualifications given by the Scottish Colleges.

Lady Louis Mountbatten, now visiting the United States of America as official representative of the British Red Cross, has conveyed to Mr. Norman Davis, chairman of the American Red Cross, the thanks of this country for medical supplies and clothing, amounting to over \$25,000,000 in value, sent to Britain.

Dr. Freda B. Pratt of Oxford has changed her name by deed poll to Dr. Freda B. Bannister.

It was announced by the B.B.C. on September 22 that the Prime Minister has asked Sir Charles Wilson, M.D., President of the Royal College of Physicians of London, to join the British Mission to Moscow in order to report to him on any medical help that should be given to Russia.

An American Red Cross Mission is now in Russia for the purpose of assessing that country's medical and other relief needs. The American Red Cross has already sent to Russia a shipment of medical and surgical materials, including insulin and gas gangrene serum. Additional emergency supplies are being prepared for shipment. The chairman of the Mission is Mr. Allen Wardwell of New York, who was a commissioner of the American Red Cross in Russia during the last war. Other members of the Mission are Mr. James D. Nicholson, Dr. George K. Strode (Assistant Director of the International Health Division of the Rockefeller Foundation), and Mr. Robert K. Scovell.

At the end of a Polish-Czechoslovak medical conference held recently in Edinburgh a resolution was unanimously adopted calling on physicians of the two countries to carry on in friendly collaboration. At a dinner given to the guests of the congress, Prof. Koskowski, vice-chairman of the committee, thanked the Scottish authorities for their hospitality and co-operation, and expressed gratitude to the Royal College of Surgeons of Edinburgh for the readiness with which it had helped the committee in getting accommodation. The Czechoslovak Minister of Social Welfare emphasized the medical and social importance of the congress. The scientific proceedings included the presentation of reports on questions from various fields of medicine, with special reference to professional work in wartime.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, W.C.1.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated.

Authors desiring REPRINTS of their articles must communicate with the Secretary, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors over-seas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

ADVERTISEMENTS should be addressed to the Advertisement Manager (hours 9 a.m. to 5 p.m.). Orders for copies of the *Journal* and subscriptions should be addressed to the Secretary.

TELEPHONE No.—B.M.A. and B.M.J.: EUSTON 2111.
TELEGRAPHIC ADDRESSES.—EDITOR, *Aitiology Westcent*, London;
SECRETARY, *Medisecra Westcent*, London.

B.M.A. SCOTTISH OFFICE: 7, Drumsheugh Gardens, Edinburgh.

QUERIES AND ANSWERS

Income Tax

Assessment and Allowances

"SENEX" completed a return for 1940-1 claiming relief in respect of bank charges, building society interest, etc., and showing £136 professional earnings. The inspector of taxes says he accepts this figure and that "it will be necessary to submit an assessment" in that amount. Nothing has been said about the claim to relief.

** Presumably the official writing the letter was dealing only with the question of the assessment of the earnings, and he will arrange for the assessment to be made accordingly. No doubt the return will be passed on to some junior official to deal with the relief claimed, but if "Senex" does not hear shortly on that aspect of the matter he might inquire what is being done about it.

Remuneration as Assistant

A. E. held a hospital appointment up to January 14, 1940; he then took an assistantship at £400 per annum, which he held until he took another similar employment as from July 14, 1940, at £500 per annum. (Car allowance and value of board and lodging are excluded as not being liable to tax.) What is his liability to assessment for 1940-1 and 1941-2?

** Continuity of employment applies to the two assistant appointments, but not to that at the hospital. 1940-1.—This is the second year of the employment assessed, and the remuneration is chargeable on the current year's basis—i.e., on 86/365 of £400

(=£94) plus 279/365 of £500 (=£382), net total £476. The assessment of £475 can therefore be accepted. 1941-2.—This, being the third year of the employment, is chargeable on the basis of the previous year, unless the person assessed claims the current year's basis. The liability is therefore £475, and notice of objection to the assessment of £500 should be given. As regards expenses, renewals of books and instruments can be claimed, but not commissions paid for obtaining appointments.

LETTERS, NOTES, ETC.

Very Hyphenated

A correspondent who attended the recent annual congress of the Ophthalmological Society at Cambridge brings back one example of a term used by a speaker there in a discussion on nystagmus which seems worth preserving. It was "Laryngo-pharyngo-palato-oculo-diaphragmatic myoclonus."

The Evacuation Scheme

"PRO SINE QUID" writes: During the past two years many changes of billets have taken place and large numbers of children have trickled back to their homes. Others have transferred from one doctor to another in the same area not once, but as often as they change their billets. In some cases children have moved miles away, and the doctor with whom they originally registered is still called in although they are miles outside his area. The doctor receives no notification of changes in his list, and he is not infrequently called in to attend later arrivals and confronted with a blank card for children who have been living in his area for a year or more, whose guardians or foster-parents have not troubled to register them with a doctor until they become ill. The result of all this is that I for one have not the slightest idea of my commitments nor of any changes which have taken place in my list. With petrol allowance nearly halved so that I cannot take any new patients, and with the increased cost of purchase-taxed drugs still rising, I should like to know how I stand. Please note that I am saying nothing about the question of remuneration, which so far as I am concerned appears to have ceased more than a year ago.

Rose-hip Jam

The following method has been suggested by the Children's Nutrition Council for using wild rose hips (a rich source of vitamin C) as a jam or purée. Pick the fruit after the first frost, and choose deeply red, ripe, but slightly soft berries, which should be cut from the stalks with a sharp knife or scissors and processed immediately, care being taken that they do not come into contact with metal, unless stainless. Take whole hips, snip off the stalks and withered buds, and wash quickly. Place in a clean enamel saucepan, cover with boiling water (using 1½ pints to 2 lb. of fruit), and boil for a quarter of an hour only. Rub through a fine sieve of hair or stainless metal, using a wooden spoon. Mix 2 lb. of the purée with 1 lb. of sugar and stir well. Dissolve and bring to the simmer. Boil for ten minutes and fill small earthenware containers. Allow the jam to cool and cover the tops with a half-inch layer of fine sugar. Cover with cellophane or the like, and keep in a cool place. The vitamin content will be retained for three or four months. According to a bulletin issued by the Children's Nutrition Council, the purée should contain about 160 to 600 milligrammes of vitamin C per 100 grammes, and the jam about 130 to 230 milligrammes. Thus there should be at least three 50-milligramme doses of ascorbic acid in slightly over three ounces of jam; half an ounce eaten daily with bread would provide a useful supplement to the vitamins obtained in a normal diet. It is interesting to note that rose hips are a traditional food of European peasants.

"Perfect Sight without Glasses"

Dr. D. OCKMAN (Kearsley, Lancs) writes: The annotation on the subject of perfect sight without glasses (September 13, p. 283) is very interesting. It is well known that the vocal apparatus can be trained to extend the range of a voice in both directions, and I should have thought that it would not be impossible to train the optical apparatus to behave with increased physiological power. The chief difficulty, as I see it, would be to find patients with the credulity, patience, and will-power required for the discipline involved. It is so much easier to put on a pair of glasses, just as it is so much easier to take atophan than to give up port and punch.

Medical Certification

A correspondent has received the following ingenuous note from one of his patients: "Dear Dr. S.—Will you kindly give me a prescription for glucose? My wife wants some for premenstrual but I can't get it without a prescription from a doctor. Yours sincerely, —."

HEAD INJURIES IN MOTOR-CYCLISTS

THE IMPORTANCE OF THE CRASH HELMET

BY

HUGH CAIRNS, D.M., F.R.C.S.

Temporary Colonel, R.A.M.C.; Nuffield Professor of Surgery, Oxford; Consulting Neurosurgeon to the Army at Home

During the first twenty-one months of war the number of motor-cyclists and pillion passengers killed on the road was 2,279—21% more than during the corresponding months of peacetime (1,884 killed between September, 1937, and May, 1939). The frequency of head injuries was high (Table I), and in a number of cases the fatal outcome might have been avoided if adequate protection for the head had been worn. But, as will be observed, the issue is not clear-cut, since multiple injuries other than head injuries undoubtedly contributed to death, though to what extent cannot be defined.

The second section of this paper deals with such material as it has been possible to collect relating to non-fatal head injuries to motor-cyclists; the third briefly indicates some of the causes of accidents, and offers suggestions for prevention and for protection to the heads of riders by the general use of crash helmets of a type described. In conclusion, 7 cases, seen by me, are reported of non-fatal injuries to riders wearing crash helmets, and evidence is adduced to show that in most of them graver injuries would have been sustained without such protection.

Fatal Injuries

Through the kindness of the Royal Society for the Prevention of Accidents and of the Registrar-General it has been possible to procure the particulars and the certified cause of death in a series of 149 fatal accidents occurring among motor-cyclists (excluding pillion passengers) in the last four months of 1940. Table I shows that in 102 of 111, or 92%, of the cases in which the cause of death is

becomes clear that, when the head injury dominated the clinical picture, other injuries often were not mentioned in the death certificate. Thus in one case there were, in addition to the head injury, fractures of humerus, fibula, and fingers; in another, fracture of one clavicle; in another, compound fracture of the femur; in two cases, bad burns owing to a petrol fire when two motor-cyclists met in head-on collision. In addition, in one other case, in which the patient was certified as dying from shock following multiple injuries, Dr. Robb-Smith found at necropsy the following injuries: fractures of the anterior and middle cranial fossae, slight subdural haemorrhage, multiple areas of cerebral contusion, fractures of the mandible, maxilla, nasal bones, compound fracture of the right tibia and fibula, and slight laceration and fat embolism of the lungs. In probably two-thirds or more of the 149 fatalities there were multiple injuries of a major character, though head injury was a factor in most of the 149.

To assert that head injury is the sole cause of death in motor-cycle accidents would be misleading, but there can be little doubt that many patients in this series would have lived if their heads had been adequately protected. It is the combination of injuries, each in itself probably not fatal, that so often produces death, as in the following case.

Case I: Fatal Injury

A man aged 22 (Serial No. 131) collided in the black-out with a lorry which had pulled out to overtake a car. He was not wearing a crash helmet. He had concussion and a compound depressed fracture of the right frontal region, a fracture-dislocation of the right ankle, and laceration of the adductor muscles of both thighs. This case has already been described in detail elsewhere (Russell, 1941, Case 2), and it is only necessary to give the main points here.

He was unconscious for three-quarters of an hour after the injury. He showed a fairly severe degree of shock, but following a transfusion he improved. He then complained of pain in the right ankle and became very restless; for this it was necessary to give nembutal and later morphine. Twenty hours after the injury he became unconscious again, and remained so until death. Forty-five hours after injury he began to have convulsive seizures, and twelve hours later he died. His pulse rate was never below 140.

Necropsy (Drs. Robb-Smith and Dorothy Russell) showed, in addition to the injuries already described, a long right fronto-parietal fracture extending on to the roof of the right orbit and involving the sphenoidal and ethmoid sinuses, which contained blood. There was also a fracture of the roof of the left orbit. The right frontal lobe showed superficial laceration of its dorsal surface over an area 5 by 2.5 cm., and the overlying dura was torn. In the brain, beneath the laceration, there was a wedge of softening and diffuse haemorrhage up to 2.5 cm. deep, and the anterior half of the right frontal lobe showed slight oedema. There were also a few punctiform haemorrhages

TABLE I.—*Certified Cause of Death in 149 Cases of Accidents to Motor-cyclists (149 Cases)*

Head injuries*	102
Head injury alone	85
" and other unspecified injuries	11
" fracture of lower limb	1
" spinal injury	1
" facial injury	1
" meningitis	2
Multiple unspecified injuries	35
Other injuries	9
Fractured jaw and pneumonia	1
Fracture-dislocation of cervical spine, etc.	1
Thoracic injury, with haemorrhage, etc.	1
Thoracic and abdominal injury, with haemorrhage	1
Abdominal injury, with haemorrhage	1
Fractures of limbs	2
Multiple fractures of limbs and crushed thorax	1

In 3 of the above cases gas gangrene was given as a cause of death. In 3 of the cases death occurred under anaesthesia for operation on the injuries.

* The term "head injury" is used to cover the following terms on the death certificate: Fractured skull, contusion of brain, laceration of brain, intra-cranial or cerebral haemorrhage following injury, oedema of brain due to injury, cerebral compression.

specified a head injury occurred. In 85 cases death was ascribed to head injury without mention of other injury, but from additional information obtained as to 10 of these cases, either from case notes or from inquest reports, it

in the convolutions of the left hemisphere. Microscopic examination revealed fat emboli in the cerebral hemispheres and choroid plexuses.

The lungs showed focal haemorrhagic zones, early inhalation pneumonia, and considerable fat embolism. The adductor muscles of the thighs were grossly torn and bruised, with haemorrhage extending up into the retroperitoneal tissues.

In this case the damage to the brain, apart from fat emboli, was almost entirely restricted to the site of impact. There was no contrecoup damage; probably neither head injury nor limb injury was in itself sufficient to cause death. The injuries as a whole caused shock, and there was blood loss from scalp bleeding. Brain damage produced restlessness, which increased the pain from the foot, and this made the patient more restless. Restlessness may have promoted fat embolism of lungs and brain.

The outlook is often far more grave when head injuries are complicated by injuries elsewhere. The pulse tends to be more rapid, pneumonic signs may set in, often as a result of fat embolism (Robb-Smith, 1941; and Rowlands and Wakeley, 1941). Such patients are in a highly critical state and may be made worse by manipulations, such as setting of their fractures. They tend to travel badly in the early stages. This may be one reason for the fairly general belief that patients with head injuries travel badly—an impression not confirmed by observation of uncomplicated head injuries.

These are some of the most difficult accident cases to treat: they require careful resuscitation, much individual attention to wounds, and continuous supervision so that the right time may be chosen for setting the limbs, operating on the head wounds, and so forth. And the patient should be moved as little as possible. It is not surprising that three of the patients in the series were reported as dying under anaesthesia.

If in Case I a crash helmet had been worn the patient's head injury would probably have been less severe and he might not have died. With equal right it could be argued that if his lower limbs had been protected from injury he would not have died. Protection of the lower limbs is obviously more difficult than protection of the head, but the problem deserves further study.

The rarity of thoracic and abdominal injuries in fatal motor-cycle accidents is to be noted (Table I). Spinal injury also appears to be rare, but is easily overlooked in an unconscious patient and also, if not specifically sought, at necropsy.

Non-fatal Injuries

It is difficult to get a comprehensive picture of the non-fatal accidents in motor-cyclists or to estimate their frequency. They are evidently fairly common, for in a series of 556 blunt head injuries of known cause admitted over a period of fourteen months to a hospital for head injuries, some in the acute stage but many more in the chronic stage, 122, or approximately 22%, were in motor-cyclists. Of the 122 patients 22 had fractures or other major injuries in parts other than the head. These included fractures in various long bones, with a slight predominance in the lower-limb bones, fractures of the mandible, dislocation of the shoulder, and one case of injury to the spinal cord. This material has the disadvantage of being selected, since the hospital is primarily devoted to head injuries. The proportion of cases showing multiple injuries is therefore probably lower than in an unselected series. There are no examples of brachial plexus injury—known to be a serious and not infrequent result of motor-cycle accidents—possibly for the reason that in accidents affecting the brachial plexus the supraclavicular region receives the force of the blow and the head escapes damage.

The site of violence to the head, as indicated by scalp lacerations or by fractures, shows a predominance of frontal injuries (Table II), but no part of the cranium is exempt. There are several cases of fractures of the occipital bone, at times extending into the foramen magnum. The common

TABLE II.—Site of the Blow in Motor-cyclists' Head Injuries (93 Cases)

Frontal	52	Parietal	17
Temporal	12	Occipital	12

injury, however, is a frontal blow, with laceration of the forehead and multiple fractures, linear or depressed, in the underlying bone. Fracture lines often extend to the roof of the orbit and to the frontal and ethmoidal sinuses, and, in the other direction, backwards along the vertex towards the parietal region. There is superficial laceration of the frontal lobes, and usually the dura is torn. Sometimes there is cerebrospinal rhinorrhoea. There is considerable haemorrhage in both orbits, and sometimes damage to an eyeball or to an optic nerve. The olfactory pathways also are not infrequently interrupted.

Causes and Prevention

Speeding, especially at corners, poor visibility in black-out or fog, skidding, overtaking, convoy duty, sudden gusts of wind from side-streets—these are some of the causes of accident. The fatal accidents have been carefully analysed by the Royal Society for the Prevention of Accidents, and the reader is referred to their *Road Accident Bulletins*, Nos. 10 and 12. No doubt the conclusions drawn from this analysis would be equally applicable to non-fatal accidents.

The most important and effective method of preventing head and other injuries is careful driving. There

FIG. 1.—Diagram of a crash helmet.

seems to be particular need to impress this obvious fact upon motor-cyclists, since they, more than users of other types of motor vehicle, appear to be exhilarated by their speed and therefore reckless in attaining it. And, unlike occupants of a motor-car, they are not protected by their machine. When motor-cycle accidents occur at high speeds no amount of protection of the head or other parts will prevent gross and often fatal injuries. It is not sufficiently realized that a slight increase in speed may produce a very great increase in the amount of damage.

It is the purpose of this paper to advocate for all motor-cyclists, civilians and fighting Forces alike,* the use of a crash helmet of the type worn by racing motor-cyclists. It consists (Fig. 1) of an outer shell of some firm substance, shaped rather like an inverted pudding-bowl and quite smooth on its outer surface. This is supported by a lining consisting of a series of web slings fitting snugly on the rider's head and attached by its base to the base of the outer shell. The helmet is also retained in place by a chin

* The requirements of troops under fire are not considered in this paper.

strap. Between the outer shell and the lining there is a gap which may with advantage contain some energy-absorbing material.

Report of Cases of Non-fatal Injury

So far I have seen only seven cases of motor-cyclists injured while wearing a crash helmet.* In all of them the effects of the head injury had been unusually mild.

Case II

A rifleman aged 23 (Serial No. 1003) had had a slight head injury, with fifteen minutes' amnesia, two months before his accident during night exercises on June 6, 1941. Riding at 30 m.p.h. he ran into the back of a stationary vehicle. He was

FIG. 2.—Case II. Damage to the outer shell and inner sling of the crash helmet in the right frontal region.

FIG. 3.—Case II. Tracing of radiograph of depressed fracture beneath the site of damage to the crash helmet.

rendered unconscious and sustained a lacerated wound on the right side of his forehead, also a simple transverse fracture of the right tibia and fibula just below their mid-points. His crash helmet was broken in the right frontal region, where part of the outer shell was detached, and beneath this gap the base of the inner sling was broken (Fig. 2). From the upper end of the gap

in the outer shell two fissures extended into the rest of the shell, each for a distance of about 2 cm. The gap in the helmet corresponded to the site of scalp laceration. Beneath the scalp wound, but slightly lateral to it, there was a double line of fracture, slightly depressed at one edge (Fig. 3), which extended into the external angular process of the frontal bone.

The duration of his retrograde amnesia was at first uncertain, but two months after the accident he had recovered memory of past events up to within four minutes of the accident. His first memory was of a time forty hours after the accident. During this period of amnesia he had a generalized convulsion, was twice given 1/4 grain of morphine for restlessness, and also had his scalp wound excised and sutured under pentothal anaesthesia.

He was transferred to a military hospital for head injuries on June 12. At that time he was conscious, lucid, and quiet, but he was a little drowsy and showed some defect of memory and concentration and very slight nominal dysphasia. Speech was otherwise normal. He was a left-handed man. He had some stiffness of the neck and very slight papilloedema. There was slight left lower facial weakness. The other cranial nerve functions and motor, sensory, and reflex functions were normal. He was complaining of considerable frontal headache. Lumbar puncture on the eighth day showed a clear colourless fluid under a resting pressure of 90 mm. H₂O, containing 0.045% of protein, and 2 lymphocytes and a few red blood cells per c.mm.

Within a few days he became normally alert, his verbal memory became normal, and his papilloedema subsided. His headache persisted unusually long, but finally disappeared after three weeks. The fractured tibia and fibula were treated by manipulation and plaster, and good union was obtained. Return to full duty was delayed by the leg fracture.

This man evidently received a severe blow on the right frontal aspect of his crash helmet, with the production of a scalp wound immediately beneath. Damage to the skull was limited to a fracture beneath the lateral edge of the scalp wound. The appearances suggested that the helmet had struck a slightly concave object which had punched a fairly clean hole in the helmet and had driven the piece of outer shell inwards. Without the crash helmet there is little doubt that a deep penetrating injury would have been produced and that the fracture, like so many of the fractures in unprotected motor-cyclists, would have spread, to involve the frontal and ethmoid sinuses and the roof of the orbit, with considerable displacement of the frontal bone and the eyeball and also laceration of the frontal lobes—an injury, in fact, like that of Case I. As it was, the brain damage was evidently inconsiderable: to judge from the lumbar puncture there was little or no intracranial bleeding, and the evidence of brain damage was limited to slight and fleeting impairment of verbal and other memories. The fact that post-traumatic amnesia lasted forty hours is certainly not a reliable indication of the extent of brain damage, since he received 1 1/2 grain morphine and intravenous pentothal during that period.

Case III

A lieutenant aged 23 (Serial No. 582) had a motor-cycle accident while on convoy duty on April 16, 1941. He was overtaking a van, probably at 40 to 50 m.p.h., when it suddenly pulled out to the right and he crashed into it. He had head injuries, a wound five inches long into the left knee-joint, and a transverse fracture of the left patella without displacement, also bruising of the right elbow and left wrist. His crash helmet showed severe injuries on the right side (Fig. 4): the paint was removed in a patchy fashion over a wide area—an indication of the extent of the violence; and there was a T-shaped fracture, with one limb running vertically downwards to the free edge of the helmet above and behind the right ear, and the other passing forwards at right angles to the first almost to the middle line in the frontal region. From the junction of the T, also, a faint crack extended backwards for 2 cm. One of the loops of the inner sling of the helmet was completely torn from its attachments.

* Since this paper was written a further 8 cases have been seen. In all except one there was considerable damage to the crash helmet. All the patients were mildly concussed; one of them had a moderately severe frontal fracture. All made a complete recovery.

On the scalp there was a superficial laceration 1.5 cm. long in the right parietal region, which lay about 1.5 cm. below the junction of the fracture lines in the crash helmet when this was comfortably worn in the usual position. The laceration was evidently produced by indentation of the helmet at the posterior end of its horizontal fracture line. The fact that the two lines did not correspond when the helmet was worn in the usual position gives some idea of the extent to which the helmet was deformed and crushed on to the head at the time of the impact, once the inner sling had broken (Fig. 5). In the skull there

first memory after the accident was about two hours later, at which time he was well orientated and showed no neurological signs. For the first few days he could not concentrate and was irritable. For ten days following the accident he had a constant, generalized, dull, throbbing headache, which disappeared a few hours after lumbar puncture (faintly yellow cerebrospinal fluid under a pressure of 140 mm. H₂O, and containing 35 mg. of protein per 100 c.cm. and occasional red cells).

His knee wound was treated with sulphanilamide, excision and suture, and fixation in plaster. He walked six weeks after the accident and recovered normal function of his left lower limb six weeks later, at which time he was perfectly well in other ways.

This case illustrates well the value of the crash helmet. A severe blow on the head was partly expended on breaking the crash helmet. It did, however, produce a fracture of the skull beneath one of the fractures of the crash helmet, also a scalp wound. In spite of the fracture of the skull the brain injury was of a minor character, producing a brief period of amnesia and several days of headache, from both of which symptoms rapid and complete recovery ensued. The areas of the helmet denuded of paint (Fig. 4) indicate that the effect of the blow (or series of blows) was widespread, an obvious advantage to the brain and possibly resulting from the smooth round surface of the helmet.

The superimposed diagram of crash helmet and skull radiograph (Fig. 5) shows that the horizontal fracture in the crash helmet is not parallel with that of the skull. It indicates also the degree to which the crash helmet must have been crushed down on to the head by the blow, since it may be presumed that at the time when the skull was actually fractured the junction of the fracture lines in the crash helmet lay approximately over the scalp laceration.

Case IV

A private aged 26 (Serial No. 914) had an accident on July 27, 1941, when he ran into a car coming out of a side turning. He had no memory of the accident or of the five minutes preceding it, but it is probable that he was travelling at about 25 m.p.h. He had no memory for fifteen minutes after the accident, but his memory of subsequent events was clear.

His motor-cycle was very little damaged. He sustained a small shallow triradiate scalp wound over the right Rolandic region, about 2.5 cm. from the middle line, superficial lacerations above and below the outer part of his right eye (he was wearing goggles, which were very slightly bent but not broken), a subconjunctival haemorrhage on the outer part of the right eyeball, bruising below the left knee, but no fracture of long bones or of skull. From the radiographs it appeared possible that slight separation of the lambdoid suture had occurred, but there was no tenderness of the overlying scalp.

His crash helmet showed no sign of injury in the region of the small scalp wound, but in the left occipital region there was a fissured fracture 7 cm. long extending vertically upwards from an area of the free edge from which the paint had been removed. The helmet was otherwise undamaged. There was no bruising of the scalp beneath the site of this split, and the discrepancy between the site of the right frontal scalp injury and of the left occipital helmet fracture is not explained.

On admission to hospital three-quarters of an hour after the accident the patient was fully conscious and orientated and quite alert. Temperature was 98.4°; pulse rate 80; and mental examination and examination of the central nervous system showed nothing abnormal. The scalp wound was closed with two interrupted stitches. The patient had headache for the first day, but thereafter he was free from symptoms. He got up on the sixth day and was discharged to duty on August 14, 1941.

Case V

A gunner aged 27 (Serial No. 996), on March 29, 1941, was on his motor-cycle riding slowly in bottom gear from a country lane into a main road. He remembered no more, but was told afterwards that a car ran into him from behind. His crash helmet was not broken, but showed an irregular area of abrasion,

FIG. 4.—Case III. Top: Fracture lines and areas of loss of paint on right side of crash helmet. Bottom: The same helmet showing loss through tearing of one of the loops of the inner sling.

FIG. 5.—Case III. Superimposed diagram of crash helmet and skull, showing lines of fracture in outer shell of helmet, scalp wound, and fissured fracture.

was a fissured fracture about 14 cm. long running forwards and downwards from immediately in front of the site of the scalp laceration almost to the outer angle of the frontal sinus.

The patient was rendered unconscious by the accident. His retrograde amnesia was no more than 1 to 2 seconds, and his

13 by 7 cm., in the left frontal region, and at the postero-medial edge of this area a shallow dent in which the material of the outer shell was softened. In the area of abrasions the varnish was removed and there were numerous curved linear lacerations in the paint running downwards and forwards in parallel lines, and deepest at the antero-lateral margin of the area (Fig. 6). One of the web slings was also torn.

Fig. 6.—Case V.—The effects of a tangential blow on the outer shell of crash helmet.

The patient had no abrasions on the scalp or fracture of the skull. The scalp beneath the site of helmet injury was marked by an area of tenderness which persisted for a few days. As indicated above, there was retrograde amnesia for a few seconds. Post-traumatic amnesia lasted twenty-four to thirty-six hours. He was kept in bed for nineteen days with at first fairly continuous left fronto-parietal headache. Then after only two days out of bed he was returned to his unit, where headaches recurred and he was sent back to hospital. During the next seven weeks he was in two different hospitals and one convalescent depot. At the end of this treatment his headaches were better and he returned to his unit for six days, during which period he had an attack of dizziness. He was returned to hospital, where, after lumbar puncture, he developed intense headache and vomiting. He became depressed and anxious about his own health and that of his wife, who was living in a bombed area and was five months pregnant. He was admitted to a military hospital for head injuries on June 26, 1941.

Inquiries showed that his upbringing had left much to be desired. In peacetime he had had considerable difficulty in getting employment. He enjoyed his life in the Army, but did not mix well with his comrades. He had a horror of bloodshed. Examination showed no abnormality in the central nervous system and only a moderate degree of intelligence. He appeared anxious to succeed at his work, but he was an unstable type of man. He was discharged from hospital on August 18, 1941.

The post-convulsional syndrome so well illustrated by this case is a problem entirely different from that with which we are primarily concerned. The case is reported in detail to emphasize the fact that crash helmets cannot be expected to prevent such a syndrome, onset of which does not depend on the severity of the initial head injury, especially in patients of poor mental stamina.

The position of the abrasions on the helmet (Fig. 6) suggests that this patient received a tangential blow, striking first the front part of the helmet to the left of the middle line and proceeding downwards and outwards to the left. This tangential type of injury is on the whole the least harmful type of blow to receive. Dirt-track riders and other experts try to throw themselves clear of the machine at the last moment before the accident. They prefer to volplane to earth and, in so doing, to escape with grazing injuries which are relatively harmless. The longer the body takes to come to rest the less is the force of impact. When

the head comes into contact with the ground it is obviously better that the outer shell of the helmet should be abraded than the scalp and skull.

Case VI

A major aged 29 had a head-on collision with Case VII while on exercises on March 27, 1941. Neither man has any memory of the accident, but probably this patient was travelling at 35 to 40 m.p.h. and Case VII at slightly over 40 m.p.h. Case VII's bicycle was a total wreck, and the front wheel and forks, handlebars, and lamps of Case VI's bicycle were destroyed beyond repair. Both patients were wearing crash helmets.

In this patient the injuries were a small wound in the occipital region one inch in front of the external occipital protuberance, two upper incisor teeth knocked out, a fracture of the upper jaw, cut lower lip, and a compound comminuted fracture of the right patella, and he was unconscious. His crash helmet showed a slight dent in the right fronto-lateral region, and its varnish had been scraped from two areas—one just below the dent and the other in the occipital region. These marks of violence were slight, and it is therefore doubtful whether his head received any severe blow. Radiographs of the skull showed no fracture. His retrograde amnesia was ten to fifteen minutes. His first subsequent memory was three or four days after the accident. During the latter part of this period he awakened readily and responded promptly to questions; he fell asleep easily, was confused and disorientated, and kept asking the same question again and again. For nearly three weeks after the accident he found, when he tried to discuss the affairs of his unit, that his memory was a little hazy. When seen four weeks after the accident he showed no abnormal neurological signs and his intellectual functions and mood were normal. He had suffered twice in earlier years from periods of depression.

Until six weeks after the accident he had recurrent frontal headaches, with occasional pain in the right occipital region and back of the neck. For a further four weeks he remained bedridden on account of his fractured patella. This was treated first by sulphamilamide dressing and plaster, then by secondary suture, and later by excision of the comminuted patella. The final result was a useful limb, with slight limitation of movement at the knee, and return to duty.

It is difficult to estimate the value of the crash helmet in this case. The marks of violence on it were slight, and much of the force to the head and neck appears to have been taken on the face. However, there was a period of unconsciousness or confusion lasting three or four days, and this suggests a fairly severe head injury from violent rotation of the head, or a milder head injury complicated by fat emboli to the brain. There was nothing remarkable about the completeness of the subsequent recovery of intellectual function, though its promptness was unusual.

The position of the superficial scalp cut must be noted. It was a transverse cut an inch long across the middle line one inch in front of the external occipital protuberance. It was within the area protected by the crash helmet. A similar scalp laceration was found in Case IV.

Case VII

A lieutenant aged 23 met Case VI head-on at a bend in the road. He was wearing a crash helmet. He had no bruises on the head or face, and x-ray examination showed no fracture of the skull. He had a compound supracondylar fracture of the right femur and a fracture of the right tibia into the knee-joint, also abrasions on the left lower limb and back. His crash helmet was smeared with blood, but there were no marks of violence on its outer surface; however, the loops of webbing on the interior were in places partly torn from their attachments. He had no memory for a period extending from about ten minutes before to between fifteen and thirty minutes after the accident. On regaining consciousness he was worried because he did not know where he was or how he had hurt himself. He lost consciousness again in the ambulance, but regained it in hospital later in the day, and thereafter was lucid. He had no headache, but was for a time a little nervous at night. He had always been highly strung. When seen four weeks after

the accident he showed no neurological signs or impairment of intellectual function.

His broken leg was treated first by extension in a Thomas splint and then by fixation in plaster. He was discharged from hospital on August 13, 1941, with a useful limb.

This patient, like Cases VI and VIII, was detained in hospital for a long time because of his leg injury, and he could have returned to duty much earlier if it had been only his head injury which required treatment.

Case VIII

A second lieutenant aged 23 (Serial No. 997) had an accident on June 12, 1941, when he had a head-on collision with an oncoming car. The front wheel of his motor-cycle was buckled and the handle-bars were bent. He sustained a head injury, a double compound fracture of the middle of the shaft of the right femur, a simple butterfly fracture of the right tibia in the lower third, and lacerations of the right knee and right hand. His crash helmet had a little blood on its outer surface, but was otherwise undamaged. There was no sign of injury to the scalp and radiographs of the skull were negative. His retrograde amnesia was one second or less, his post-traumatic amnesia no more than a few minutes. He states that he was lucid after that, but the hospital notes say that he was irrational for the first few days following injury. During that time he complained of headache, though subsequently he denied ever having had any.

When seen eleven days after the accident he was lucid and co-operative and showed no neurological signs or impairment of intellectual function, notwithstanding slight infection of the thigh wound and nocturnal fever. His lower-limb fractures presented a difficult problem of treatment. Extension for the femur was obtained by a Steinmann's pin through the upper end of the tibia, and the tibial fracture was fixed by open operation.

The head injury was obviously very slight in this case, and there is no evidence that the crash helmet in any way decreased its severity.

Discussion

It is difficult to collect conclusive evidence in favour of crash helmets. No hospital capable of studying this problem receives unselected cases, and it is impossible to judge from any figures available the seriousness of motor-cyclists' head injuries. Some motor-cyclists die on the road. Others are admitted to the nearest hospital and may die within the next two or three days, or, if they recover, may eventually find their way to a central hospital or back to work. Mild cases may never go to hospital at all. Little help can be obtained from central records, since the relevant information is scattered in several different Government Departments.

Though the seven cases reported here cannot be regarded as representative, they constitute, when considered individually, an encouraging experience with crash helmets. In all of them there was concussion. In four cases the damage done to the helmet was considerable: in three (Cases II, III, and IV) the helmet was fractured, and in another (Case V) it bore the marks of a severe tangential blow. In two cases (Cases VI and VII) the damage to the helmet was slight. In Case VIII there was no evidence of damage to the helmet, and it is not impossible that the mild concussion resulted from violence transmitted to the cranium through the spinal column. In the other six cases, however, there is clear evidence of a blow on the head.

In Case II a portion of the helmet appears to have been punched out, and beneath the gap there was a scalp wound and a slightly depressed fracture (Figs. 2 and 3). In Case III the force of the blow was applied over a wide area of the helmet covering the right parieto-frontal region, with the production of an extensive T-shaped fracture in the outer

shell (Fig. 4); in addition to a fissured fracture of the skull there was a small scalp wound, from the position of which it was possible to judge to what degree the outer shell of the helmet had been jammed down on to the head at the time of injury (Fig. 5). This extreme displacement of the outer shell could only have occurred when the inner lining of the helmet had given way as a result of one of the slings being torn from its moorings, as shown in Fig. 4. The case illustrates the importance of a strong inner lining.

The crash helmet used in these cases did not invariably prevent fracture of the skull, but it is probable that it did prevent the fracture from spreading as far as it otherwise would have done. In frontal injuries when there is no crash helmet the fracture usually extends back along the roof of the orbit and into the accessory nasal sinuses, whereas in the frontal injury of Case II the fracture was limited to the area of damage of the crash helmet.

The brain damage in all cases was remarkably slight, as judged by the absence of neurological signs and by the promptness and completeness of the recovery of intellectual functions. To be sure, head injuries of similar mildness do occur in motor-cyclists who have not worn crash helmets, but in accidents of the type of Cases II, III, and V the initial neurological disturbance is usually much greater and the recovery slower, though not necessarily less complete.

Theoretically there are certain disadvantages in the crash helmet. It increases the diameter of the head and so the leverage, thus enhancing the possibility of broken neck or rotational acceleration within the cranium. But if the helmet is adequately designed to deaden the blow, then the leverage of the blow is also deadened. Further experience is required to settle these points, and doubtless there is still considerable work to be done in improving the means of diverting the energy of the blow from the brain. It is to be hoped that surgeons will report their observations of head injuries in which crash helmets have been worn.

The frequency of fractures of the lower limb in this series calls for some comment. Five out of the seven patients had severe fractures of the lower limb, four affecting the right lower limb and one on the left side. This series is too small to permit conclusions to be drawn, but Mr. J. C. Scott has kindly supplied me with figures from the Wingfield-Morris Orthopaedic Hospital which suggest that there is a greater tendency to lower-limb fractures, especially compound fractures, in motor-cycle accidents than in other types of accident (Table III). In 10 fatal cases

TABLE III.—*The Relative Frequency of Fractures of the Lower Limb, due to Motor-cycle Accidents, at the Wingfield-Morris Orthopaedic Hospital during Twelve Months from June 1, 1940*

	Upper Extremity	Lower Extremity
Motor-cycle accidents ..	17 (2 compound, 15 simple)	40 (14 compound, 26 simple)
Other causes	196 (26 compound, 170 simple)	220 (24 compound, 196 simple)

of my series in which full details of the injuries were available. 5 had fractures of the lower limb and 2 had fractures of the upper limb. If by the general use of crash helmets the number of fatalities in motor-cycle accidents is reduced it may be expected that the number of severe fractures of the lower limb requiring prolonged treatment will increase. Their prevention deserves further study.

Summary

In a series of over one hundred fatal accidents to motor-cyclists 92% suffered from head injury and approximately 66% had multiple injuries of a major character.

When non-lethal head injury is combined with other major but non-lethal injuries death may readily occur from cerebral fat embolism and other causes. Alleviation of the head injury by means of a suitable crash helmet may be expected to save life in some cases of this type.

The most effective method of preventing head injuries in motor-cyclists is careful driving. In addition the use of a crash helmet is advocated.

Seven accidents to motor-cyclists wearing crash helmets are reported. In all of them the head injury was mild, though in four there had been considerable damage to the crash helmet.

The incidence of fractures of the lower limb is greater in motor-cycle accidents than in other types of accident, and the number requiring prolonged treatment may be expected to increase when fatalities are averted by the use of a suitable crash helmet.

I am deeply indebted to Dr. H. Holbourn, D.Phil., for his help during the preparation of this paper, to the various people and organizations mentioned in the text, to the medical officers of a military hospital for head injuries under whose care most of these cases were, and to the Medical Research Council, who provided a grant in aid of the clinical note-taking. I wish also to thank Lieut.-Col. J. A. A. Pickard, D.S.O., for enabling me to study the records of the Royal Society for the Prevention of Accidents.

A CASE OF CONGENITAL BILATERAL RENAL HYPOPLASIA WITH A SHORT REVIEW OF THE LITERATURE

BY

J. ELLIOT MURRAY, M.D., Ch.B.

Consulting Physician to an E.M.S. Hospital

AND

R. A. SANDISON, B.Sc., M.B., B.S.

Resident Medical Officer at an E.M.S. Hospital

Numerous cases of unilateral renal hypoplasia compatible with adult life have been described, but no case of bilateral renal hypoplasia in which the subject survived to adult age seems to have been reported. Indeed, very little mention of the condition has been made by observers in the past. Herbst and Apfelbach (1935), referring to this subject, state:

"Hypoplasia of the kidney was known to Blasius in 1677. Ballowitz (1895) assembled 20 cases, Risel (1903) 36 cases. Since that time many cases have been added to the literature, some of which are definitely hypoplastic, whereas others should be classified as acquired atrophy or one of the other forms of congenital anomaly." . . . According to Papin, hypoplastic kidneys are more frequently found in men than in women, and the right side is more often affected. It has been found in all ages, from the foetus to advanced life. In the living it is always unilateral, since if bilateral it could not sustain life. It may lie in a normal position or may be ectopic. The renal pelvis is usually small and frequently cone-shaped with small calices, some of which may be rudimentary in type."

Marion (1939) stated that congenital hypoplasia of the kidneys can be found on both sides, but he does not dilate further on the condition, merely stating that he had never seen a case.

Eisendrath (1935) has recorded 17 cases of unilateral hypoplasia, and Johnson and Wayman (1936) 8 cases. Eisendrath makes the following points in the diagnosis of the condition:

1. Intravenous pyelography may indicate the extent of the renal parenchyma.

2. Retrograde pyelography may show: (a) a triangular or ampullary pelvis, with minor calices arising direct from the pelvis proper without intermediary major calices; (b) the presence of only one or two calices arising from a very small pelvis.

3. Cystoscopy is of little value. A rudimentary or occluded ureter may be found.

4. The presence of a small kidney shadow.

In describing the developmental anomalies of the kidneys, of which hypoplasia is one, it is necessary to distinguish carefully between the various conditions which have been described. Mayers (1940), in a classification of renal anomalies, recognizes the following developmental abnormalities:

Congenital Hyperplasia.—Increase in size or number of cellular units—for instance, long kidney, large kidney.

Congenital Hypoplasia.—A macroscopically recognizable kidney—for example, infantile kidney.

Congenital Aplasia.—Hypoplasia to a degree which is not recognizable macroscopically, but of which there is histological evidence.

Congenital Agenesis.—Complete absence of development, therefore no evidence of renal tissue. This may be either bilateral or unilateral (congenital solitary kidney).

A definition of the pathological picture of congenital hypoplasia is given by Johnson and Wayman (1936) as "an abnormally small kidney with fewer glomeruli than normal. These glomeruli are less closely packed together and are often larger than normal."

In connexion with aplasia and agenesis a rigid distinction between these two conditions has not always been made in the literature. Hinman (1940) states that congenital bilateral absence of the kidneys has been recorded 135 times since 1663. He goes on to say that proved bilateral agenesis—i.e., true non-formation rather than secondary atrophy—is even less frequent, for only recently has microscopical examination been carried out to ascertain the presence or absence of atrophied remnants of the metanephros. The majority of these cases of renal agenesis were associated with gross malformations of the other organs.

With regard to the frequency of these conditions, Soloway (1939) states that unilateral renal agenesis is found once in about a thousand necropsies, while bilateral renal agenesis occurs once in about six thousand necropsies. As indicated above, unilateral renal hypoplasia is relatively common, while bilateral renal hypoplasia is, unlike bilateral renal agenesis, almost unknown. The aetiology of these conditions is not known. Hinman (1940) believes that they are all due to developmental arrest, and that the ultimate stage reached (whether agenesis, aplasia, or hypoplasia) is one only of degree. He also admits the rare possibility of an inherent defect in the germ plasm. The following is a report of our case.

Case History

The patient, a man aged 22, a compositor in civil life, had joined the Army on September 23, 1940. He had always enjoyed good health until his present illness. His mother and father, aged 45 and 50 respectively, are alive and well and have never had any serious illness. There is no family history of any renal disease. The mother is said to have received sanatorium treatment many years ago. There is one sister, aged 20, who had infantile paralysis at 2 years of age, which resulted in weakness in the right leg. There is no history of miscarriages or stillbirths in the family. Both grandfathers of the patient are dead, the cause of death not being known. Both grandmothers are alive and well. The patient has never had rheumatic or scarlet fever; the tonsils were removed during childhood, but there is no record of any renal complications. The patient has never previously suffered from any urinary disturbance such as oliguria or frequency.

On October 8, 1940, he had a shivering attack and headache. His nose felt "stuffy" and the throat dry. No actual cold developed, but there was a slight dry cough. After a few days he produced some white sputum. The shivering disappeared, and about five days later he started vomiting, the attack lasting four days. He had no appetite, and on October 18 was slightly jaundiced. The vision became blurred on one occasion. On October 21 he reported sick and was admitted to an E.M.S. hospital.

On examination he looked ill, he was very drowsy, the tongue was dry, and the conjunctivae were slightly jaundiced. The temperature was normal and the pulse 52. There were no abnormal signs in the heart or lungs. The blood pressure was 130/85. The blood urea was 356 mg. per 100 c.cm., the red cells numbered 3,610,000 per c.mm., and the haemoglobin was 70%. The urine contained albumin ++, but no casts or red cells were seen.

The patient was transferred to our hospital on October 23 with a diagnosis of uraemia, and he remained there until his discharge on April 27, 1941. On admission the tongue was furred but moist, and he was somewhat drowsy, but his general condition was good. The cardiovascular system showed no abnormality and the blood pressure was 130/80. The optic disks were normal, with large physiological cups and a tigroid fundus background. The urine, specific gravity 1020, contained albumin ++, sugar nil, red blood cells +, pus cells +, a few crystals of uric acid, and no organisms. The blood urea on October 28 was 300 mg. per 100 c.cm. The van den Bergh reaction was within normal limits.

SUBSEQUENT PROGRESS

The patient was kept in bed on a low-protein diet. The output of urine was at first small, but after two to three weeks it increased considerably in volume. By December 2 he felt his normal self again, having made steady progress. The blood urea had fallen progressively, and was 200 mg. per 100 c.cm. on December 2. He was then passing large quantities of pale urine of low specific gravity, containing from 0.15 to 0.20 gramme of albumin per 100 c.cm., estimated by Esbach's method. At this point he was allowed up, and he felt very well. The diet had meanwhile been slightly increased in protein. The blood pressure was 124/86. The blood urea on one occasion was 117 mg. per 100 c.cm., but it would not drop any lower. The urine contained granular casts on occasion. On November 9 intravenous pyelography was carried out, but there was no excretion of dye up to forty minutes.

On December 25 the blood urea was still high, and in a further effort to lower it he was confined to bed for two months. During this period the blood urea never fell below 101 mg. per 100 c.cm., and mostly fluctuated between 130 and 160 mg. In view of the failure of this treatment and his continued good health he was allowed up, and a month later was sent on leave. Immediately after his return to hospital, on April 10, 1941, the blood urea was 130 mg. per 100 c.cm. He continued to keep reasonably well, although he was easily fatigued and not fit for more than light work. There was still moderate albuminuria, and his condition had changed but little during the past four months. He was discharged from the Army, and on April 27 he left hospital to take up his civilian occupation. The blood pressure was then 130/82, and at no time was there any evidence of cardiovascular hypertrophy.

While in hospital the following additional laboratory findings were obtained:

Urea clearance: 9% average maximum normal on November 5, 1940; 4.8% average maximum normal on February 26, 1941.
Plasma CO₂, 29 volumes per 100 c.cm. on November 5, 1940.
Plasma proteins, 6.6%.
Blood cholesterol, 194 mg. per 100 c.cm.
Serum calcium, 8.4 mg. per 100 c.cm.
Serum phosphorus, 4.9 mg. per 100 c.cm.
Blood phosphatase, 15 units per 100 c.cm. on March 20, 1941.

X-ray Findings.—As mentioned above, intravenous pyelography on November 9 revealed no excretion of dye up to forty minutes. When repeated on January 20, 1941, it gave the same result. Retrograde pyelography of the left renal tract on February 15 and of the right side on March 20 clearly showed the renal shadows, and both were abnormally small. It is regretted that owing to paper shortage it has not been possible to reproduce

the original films. The accompanying diagrams, however, indicate the state of affairs. The normal kidney lies between the level of the upper border of the twelfth thoracic vertebra and the third lumbar vertebra, the right kidney being slightly lower than the left (Fig. 1). In the films the right kidney shadow

FIG. 1.

FIG. 2.

FIG. 1.—Outline diagram from a radiograph taken after retrograde pyelography in a normal healthy young adult.

FIG. 2.—Outline diagram from a radiograph taken after retrograde pyelography in our patient, showing features referred to in the text.

extends from the middle of the first to the lower border of the second lumbar vertebra, and the left kidney shadow extends from the lower border of the twelfth thoracic vertebra to the lower border of the second lumbar vertebra (Fig. 2). The kidneys are therefore normal in relative position, but each is only about half the normal size. The right renal calices are only two in number, and are flattened and deformed. The right renal pelvis is small. The left renal calices are three in number, but are flattened and deformed also. The left renal pelvis is fairly normal in appearance. The course and appearance of the ureters are within normal limits.

Cystoscopy showed that the bladder and the ureteric orifices were normal, as were the external genitalia, and there was no evidence of any other congenital anomalies.

Discussion

Although we were not in a position to carry out a post-mortem examination the following points enabled us to make a diagnosis of bilateral congenital hypoplasia of the kidneys:

1. The sudden onset of uraemia in a young adult without a previous history of renal disease is a feature of the case. Such a history is also characteristic in polycystic kidney, which is the only other bilateral congenital renal insufficiency known. This lends considerable support to the conclusion that the lesion is congenital.

2. The x-ray findings conform to the conditions laid down by Eisendrath (1935), quoted above, in the following particulars: (a) The kidney shadows are small. (b) There is a decrease in the size of the renal pelvis, with only two major calices on the right side. Flattening and deformity of the calices are present on both sides.

3. The absence of cardiovascular hypertrophy favours a congenital rather than an acquired lesion. According to Oppenheimer (1934) hypertension is found in only 57% of cases of polycystic kidneys. In chronic interstitial nephritis, with the so-called secondary contracted kidneys, it is exceedingly rare not to find hypertension.

The alternative diagnosis of chronic interstitial nephritis may be ruled out in view of the absence of any history of previous nephritis, the presence of definite x-ray evidence of deformed renal calices and pelvis, and the absence of any cardiovascular hypertrophy.

It has been stated by Herbst and Apfelbach (1935) that bilateral hypoplastic kidneys are incompatible with life.

The question whether this is so or not depends entirely on the number of functional glomeruli present in the hypoplastic kidneys. The normal kidney has an enormous reserve, and kidneys which possess at least a minimum number of functional glomeruli will certainly be compatible with life, just as the grossly damaged kidneys of polycystic disease or of Bright's disease may be able to support life for a number of years.

Among the other remarkable features of this case is the maintenance of reasonably good health with grossly inefficient kidneys. This suggests that a tolerance has been established to a high non-protein nitrogen in the blood over a number of years. It may here be remarked that this is good evidence that hypertension is more unfavourable to the patient with Bright's disease than is the glomerulotubular damage. Other points to be noted are the absence of any sign of renal infection and the relatively unchanged blood chemistry, apart from the blood urea. The latter findings also support the conclusion that the condition in this case is a congenital one.

Summary

A review of the literature on congenital developmental anomalies of the kidneys is given, with particular reference to hypoplasia, aplasia, and agenesis.

A case of congenital bilateral renal hypoplasia is described; this is believed to be the first one recorded in the literature.

Certain unusual aspects of the case, and the differential diagnosis, are discussed. Comparison is made with congenital polycystic kidneys, to which the condition bears considerable clinical resemblance. It is recorded that bilateral congenital hypoplasia of the kidneys is compatible with a reasonably healthy adult life.

We are much indebted to Dr. W. D. Nicol for permission to publish this report.

A REVIEW OF DYSPESIA IN THE ARMY

BY

C. A. HINDS-HOWELL, B.M., M.R.C.P.

Temporary Major, R.A.M.C.; Medical Specialist

The present paper is a report on the dyspepsia in a military hospital during the year 1940. This hospital is situated in an area in which all types of troops are represented. During 1940, 8,702 medical cases were seen either as in-patients or out-patients: of these, 1,270 (14.6%) were diagnosed as disorders of the stomach or duodenum. I have collected the notes of 804 cases which were under my care, either in the gastric unit or as out-patients, during the first fifteen months of the war (October, 1939, to December, 1940). There were 420 out-patients and 384 in-patients, this latter figure referring only to cases admitted since April, 1940, when a gastric unit of fifty beds was formed. This unit was instituted so that uniformity in diagnosis and disposal could be achieved; and although the problems of administration, of dieting, and of investigations were simplified, there were great disadvantages in having these patients in a single ward together. Of the 804 cases 91 were Canadian, 6 New Zealand, and 707 (31 officers, 143 N.C.O.s, and 533 other ranks) British. There were only a few patients from the Dominions, because they operated their own hospitals.

The diagnosis may be summarized as follows. Dyspepsia of all types, 804 cases: gastro-duodenal dyspepsia, 742 (92.3%); peptic ulceration, 424 (52.7%).

During the early months of the war dyspepsia of all types was most commonly found in Reservists, but it has now been observed to be equally prevalent among men called up in the "Army classes." The numbers naturally varied with the class of troops in the area at the time. However, dyspepsia does seem to be rare in Regulars. Although occupation was recorded in over half the cases it was of no great value because of the difficulty of classifying the results. In the majority the duration of symptoms was between two and five years. In only 10% did symptoms originate during service in the Army, and of these 80 patients 13 were neurotic in character. It is noteworthy that of the 91 Canadian patients 47 developed symptoms only after arrival in this country.

In order to make a diagnosis it is of the utmost importance that an accurate and detailed history taken in chronological sequence should be compiled. Of the special investigations radiographs were most valuable. The fractional test meal was of only partial value, as it was found that with patients who had experienced difficulty in swallowing the tube abnormal curves were recorded. The most extraordinary curves were obtained when an air-raid warning had been sounded during the test.

Transferred (no diagnosis*) ..			22

* These cases were transferred to E.M.S. hospitals before a definite diagnosis was made. The majority had the hyperchlorhydria type of dyspepsia.

Peptic Ulcer

In the British series there were 391 (55%) patients with definite evidence of peptic ulceration—a high figure, but one which would have been higher if it had been possible to make allowances for "missed ulcer" cases.

Age.—The ages at which symptoms were first noticed by the patients are recorded in the accompanying graph. It will be seen that the highest incidence for duodenal ulcer is between 20 and 30, and that the same is true of gastric ulcer, although the curve is flatter.

Past History.—In the patients with past histories were found 35 who had had acute haemorrhage, 26 of them by haematemesis. Nine with melaena was probably an underestimate, as although a story of "black stool" was common it was found very difficult to separate a pharmacological from a pathological cause, and only "proved cases" were

recorded in this period only 13 developed symptoms after the war began. They were not a conspicuous group.

Surgical Cases

Surgical cases are not included in the series, but 18 gastro-duodenal operations were performed during 1940. These included 13 for perforated ulcer, 3 partial gastrectomies, 1 gastro-enterostomy, and the closing of 1 gastro-enterostomy.

Disposal

Disposal still remains a major problem, for cases of general dyspepsia are often passed into the Army during a quiescent period; in the majority of cases, however, it is not long before the inevitable recurrence of symptoms begins, and as there can be no adequate provision of a gastric diet in the units the condition progresses. In the case of men with proved ulcers it is accepted that they are unfit for military service. In the case of officers it is often justifiable to retain them for home duty, when they can "live out" and get themselves a suitable diet. The practice of "living out" on a diet is also occasionally justifiable with an N.C.O. or other useful man.

In the remaining large group who have no ulcers the problem remains. Those with long-standing dyspepsia can be "boarded" out of the Army, but those with short histories generally find their way into Category C. Here they do practically no work of any value, and spend their time being "fully investigated" at each station to which they are posted. Many of these genuine dyspeptics are capable of useful civilian work, and in my opinion any of them who do not earn their keep in the Army should be "boarded" out of it, regardless of whether their symptoms are psychological or pathological in origin. Dyspepsia lends itself to malingering, but this in my experience is rare, although there is a certain amount of exaggeration of symptoms.

Summary

A review is given of the dyspeptic cases admitted to a military hospital during 1940 and of the notes of 804 patients seen between October, 1939, and December, 1940.

Peptic ulceration was present in 52.7% of all cases, and was spread equally between Reservists and the Army classes, but was rare in Regulars.

Duration of symptoms of dyspepsia was between two and five years, only 10% of patients developing symptoms while in the Army.

Of Canadian patients 50% developed symptoms after arriving in this country.

Of British cases 55% had peptic ulceration, the highest age incidence being between 20 and 30; 35 had had acute haemorrhage; 34 had perforated, and 29 had had a laparotomy performed.

Attention is drawn to the unreliability of the timing of the onset of pain as a diagnostic factor, and to the frequency of vomiting.

Neurotic dyspepsia was not particularly common.

Disposal is discussed.

Graph showing age of onset of symptoms. The broken line denotes duodenal ulcer; the continuous line, gastric ulcer.

included. Eighteen other cases were admitted to the hospital with acute haemorrhage. Thirty-four patients had had a perforated peptic ulcer in the past. Twenty-nine others had undergone a short-circuiting operation. Those patients who had had a gastro-enterostomy performed, and in whom symptoms returned, did not have relief for more than two years, although in only six did a jejunal ulcer develop. Twenty-nine cases had had appendectomy for the relief of duodenal symptoms, but again relief was only for some two years.

Symptoms.—The timing of the onset of pain was unreliable as a diagnostic factor; for although in the case of gastric ulcer the pain usually came on within an hour of taking food, many patients with duodenal ulcer showed the same timing. In fact, the pain from a duodenal ulcer might come on at any period from one to three hours after food. Vomiting was almost universal, and in most cases of either gastric or duodenal ulcer gave partial or complete relief. Vomiting was far commoner in soldiers than in civilians.

Signs.—No data were available for actual weights, but the cases showed no evidence of serious undernutrition. Dental sepsis or the lack of teeth was not appreciable. Epigastric rigidity and tenderness, although usual, were not universal.

Gastro-duodenal Dyspepsia

"Pylorospasm" and "irritable stomach," purely radiological diagnoses, have been used here for want of more definite terms. The group included a certain number of missed ulcer cases, some cases of neurotic dyspepsias, and probably some of dyspepsia reflex from other organs, but in no instance was there definite evidence of the exciting cause. In the large group of gastritis or duodenitis vomiting was a very common symptom, and was out of proportion to the severity of the rest of the symptoms. In this group, also, there was slight loss of weight without evidence of serious wasting.

Reflex Dyspepsia

The reflex dyspepsia cases represent only those admitted to the gastric ward with a diagnosis of gastro-duodenal dyspepsia. The majority of cases of straightforward reflex dyspepsia never reached the gastric ward, but were treated in other wards as chest or abdominal cases, according to the primary diagnosis. Of the neurotic dyspepsia patients

C. V. Craster and H. Simon (*J. med. Soc. New Jersey*, 1941, 38, 362) state that in 1940 in the City of Newark, N.J., out of 1,577 reported cases of pneumonia 1,123 (71%) were treated by chemotherapy alone. In 1,033 patients treated by sulphapyridine alone the fatality rate was 7.4%, in 86 cases treated by sulphathiazole alone the fatality was 7%. In 13 cases treated by serum alone the mortality was 7.7%, in 126 cases treated with sulphapyridine plus serum the fatality was 11.1%, and in 203 cases which received neither serum nor chemotherapy the mortality was 29.4%.

CRUSH INJURY WITH RENAL FAILURE AND RECOVERY

BY

GUY BLACKBURN, M.Chir., F.R.C.S.

Chief Assistant to a Surgical Unit, St. Bartholomew's Hospital;
Surgeon to an Emergency Hospital

AND

W. W. KAY, M.Sc., M.B., F.I.C.

Assistant Pathologist at Archway Group Laboratory, London
County Council; Chemical Pathologist to an
Emergency Hospital

This paper gives an account of a case of crush injury with acute renal failure in which recovery occurred, although the injured limb had eventually to be amputated. An important part of the treatment was the use of sodium bicarbonate to restore the alkali reserve during the period of renal failure. The main clinical and biochemical data are summarized in the table and the chart.

Case History

As the result of a bomb explosion a man 58 years old lay for twelve hours with his left thigh crushed under fallen masonry. He remained fully conscious throughout this period and was able to converse with rescue workers. By the time he was released two superficial lacerations of the left hand and left eyebrow were giving him some pain, but his mind was still clear and the crushed limb painless.

On admission to the emergency hospital some twenty hours after the explosion the man's general condition was fair, without signs of shock. The apparent site of crushing extended from the level of the left great trochanter not more than four inches downwards, but there was no abrasion or demonstrable haematoma. The injured limb was anaesthetic and completely paralysed, and there was foot-drop. Good pulsation could be

felt in all the main vessels of the limb. X-ray examination showed no injury to pelvis or femur. Simple dressings to the lacerations of the face and hand and a plaster back splint for the left foot were all that seemed necessary.

Chart of case.

During the next three days—i.e., the second, third, and fourth days of illness—there was little change in the patient's general condition, but his output of urine fell sharply, being 34 oz. in the third day and only 7 oz. in the fourth. The urine was blood-stained and had to be withdrawn by catheter on two occasions. In our experience of air-raid casualties, no matter what the site of injury, and even in the absence of any form of urinary obstruction, inability of the conscious patient to pass

Table summarizing the Main Clinical and Chemical Data

Day of Illness	General Condition, Treatment, etc.	Blood Pressure		Fluids		Urine		NaHCO ₃ given (gm.)	Blood Urea (mg. per 100 c.cm.)	Urea Clearance % of normal	Plasma		Serum

120	Hb 94%	124	80						30	53				

urine voluntarily is not uncommon. This patient had no prostatic enlargement or urethral obstruction, and has passed urine without difficulty since the fourth day of his illness. On that day the main feature was a severe cough due to diffuse bronchitis, which cleared up after treatment with 10 grammes of sulphanilamide in the next forty-eight hours. It must be pointed out, however, that in view of the renal damage in this type of case it is generally desirable to avoid the use of sulphanilamide.

On the fifth day the injured limb was giving rise to much pain and showed deep oedema from the groin to the middle of the thigh. There were one or two vesicles in the skin below the apparent site of crushing. In other respects, however, the condition in the limb was unchanged, pulsation in the vessels being still apparently normal. This day's urinary output was 19 oz., which, together with evident dehydration, a blood urea of 234 mg. per 100 c.cm. (normal 25-40), a plasma alkali reserve of 49 volumes CO₂ per 100 c.cm. (normal 55-77), and plasma chlorides of 536 mg. per 100 c.cm. (normal 560-620), indicated severe impairment of renal function. Accordingly, 1,000 c.cm. of a 2 per cent. solution of sodium bicarbonate (equivalent to 20 grammes of NaHCO₃) was given by a rectal drip.

The next (sixth) day, however, the blood urea had risen to 333 mg., and the alkali reserve had fallen to 38 volumes CO₂, and the plasma chlorides to 496 mg. The urine contained albumin and granular casts, and the patient's general condition was obviously worse. Fluid administration by intravenous drip was therefore started, 1,000 c.cm. of normal saline, followed by 1,000 c.cm. of 5% glucose in one-fifth normal saline, being so given. In view of the low alkali reserve, and the low plasma chloride content it would have been better to continue with normal saline until the chlorides were within normal limits, and to give sodium bicarbonate by mouth. The urinary output increased to 78 and 68 oz. on the sixth and seventh days respectively, and the patient seemed materially better. On the seventh day five injections of eucortone, each of 1 c.cm., were given.

On the eighth day, however, his blood urea was 324 mg. per 100 c.cm. and his alkali reserve still only 39 volumes CO₂. The condition of the lungs contraindicated the intravenous administration of fluids; the oral administration of sodium bicarbonate was therefore started in 4-gramme doses every four hours, being later reduced to 12 grammes a day, so that a total of 96 grammes was given in the course of the next seven days (see table and chart). In addition extra salt was given in his diet. The urinary output subsequently remained steady at 70 to 80 oz. a day, and progress in the clinical condition was steadily maintained. The blood urea fell gradually to normal and the alkali reserve rose to 89 volumes CO₂ per 100 c.cm. on the fourteenth day, when the sodium bicarbonate was stopped; after remaining high for some days it later became normal. The albumin and casts disappeared from the urine on the ninth day; and the blood pressure fell from 195 mm. Hg systolic and 95 mm. Hg diastolic on the seventh day to 135/80 mm. Hg on the fifteenth day. The degree of renal recovery is indicated by the rise in the urea-clearance value (calculated from twenty-four hours' output of urine) from 9.3% of normal average on the ninth day to 57% a week later. The present urea clearance, on a two-hour test, is 53% of normal average.

The changes in the plasma chlorides and serum sodium and potassium are shown in the table and chart. The chlorides fell early to subnormal levels and only slowly recovered. The serum sodium content has been normal throughout (325-350 mg. per 100 c.cm.), except for the value on the eighth day. The serum potassium content, however, was 25 mg. per 100 c.cm. on the sixth day (normal 16-22), and then fell steadily, becoming subnormal at 11.8 mg. on the sixteenth day before being stabilized at the normal level.

Mild jaundice—direct van den Bergh reaction weakly positive, serum bilirubin 1.2 mg. per 100 c.cm.—was apparent about the fourteenth day, but slowly cleared up without special treatment. As the patient had not had any blood transfusion, this was probably related to a low degree of liver damage associated with his toxic state.

The subsequent clinical course has not been uneventful. In the succeeding two months the injured limb showed little

change, the oedema subsiding slowly, only to be followed by gross wasting. Pain in the limb was persistent and severe, both at rest and on passive movement, and only 15 degrees of flexion were obtained in the hip and knee in spite of physical treatment. Then two sloughing ulcers appeared, one over the head of the fibula and the other at the heel, and showed little sign of healing in three weeks. In addition the limb, still paralysed and painful, appeared once more to be endangering the patient's life. Accordingly, after a period when the patient was too ill to operate on, a mid-thigh amputation was successfully performed, almost fifteen weeks after the date of injury.

Pathological Report.—Of the tissues of the injured limb Dr. Joan M. Ross reports: "The sciatic nerve shows some fibrosis of the interstitial tissue with slight lymphocytic infiltration. There is slight scarring of the individual nerve bundles. The vessels show the changes usual in peripheral vascular degeneration. There is some medial degeneration with calcification in the artery and an associated atherosclerosis. The veins are normal. Sections from the vastus muscle show a multiplication of muscle nuclei and a development of young fibrous tissue among muscle fibres. The appearance is consistent with a healing crush injury." It seems probable that the degree of arterial degeneration was an important factor in determining the need for amputation.

The change in the man's outlook since his operation has been very striking and satisfactory. In contrast with the early weeks, when his general condition, the severe pain in his injured limb, and the loss of other members of his family in the raid made him depressed and miserable, he now discusses the prospect of returning home and getting about on an artificial limb, and rarely complains at all.

Summary

A case of crush injury with renal failure and recovery is described.

The administration of sodium bicarbonate to raise the dangerously low alkali reserve and the giving of sodium chloride played a decisive part in restoring renal function.

Amputation of the injured limb ultimately became necessary, and should be taken into account in similar cases in assessing prognosis.

We are indebted to Mr. Basil Hume for permission to publish this case, which has been under his care, and for his advice and criticism; and to Dr. E. G. L. Bywaters for seeing the patient.

HENRY LESTER INSTITUTE, SHANGHAI

The annual report for 1940 of the Henry Lester Institute of Medical Research, Shanghai, describes continued widespread activities, despite restrictions imposed by the war. Fifty-eight original papers were published during the year under review. Many cases of nutritional deficiency were investigated, chiefly beriberi and pellagra. During the latter part of the year a study was made of more than a hundred cases of ariboflavinosis. Various types of eye lesions were found; also mouth lesions and seborrhoeic dermatitis. The eye lesions responded most rapidly to riboflavin treatment, signs and symptoms beginning to recede within forty-eight hours. Several cases of pellagra were found to be suffering from fasciolopsis infection, while infestation with ascaris frequently, and with hookworm occasionally, was present in patients suffering from nutritional deficiency. The report states that evidence is being accumulated to test the theory that intestinal parasites may consume vitamins, especially the vitamin B groups, so that with a heavy infection and a low vitamin intake a condition of avitaminosis is produced in the host. Experiments were carried out on some four hundred children in a refugee camp to test the efficiency of soy-bean powder mixture. This substance contains soya bean powder, sugar, starch, sodium chloride, and calcium carbonate. After a period of four months it was found that children fed on this mixture showed greater growth and suffered less sickness than control children fed on ordinary diet.

THE BACTERIOLOGY OF AIR-RAID WOUNDS EXAMINED WITHIN FORTY-EIGHT HOURS OF INFLECTION

BY

E. T. C. SPOONER, M.A., M.R.C.S., L.R.C.P.

(Working for the Medical Research Council)

It was suggested by Stokes and Tytler (1918) and by Fleming and Porteous (1919) that in the war of 1914-18 pyogenic cocci, in particular *Streptococcus pyogenes*, entered wounds chiefly during their treatment in hospital. Miles *et al.* (1940) have found evidence of hospital infection of wounds during the present war.

In order to determine whether pathogenic bacteria are carried into wounds when they are inflicted it is necessary to examine the bacteriology of very early wounds. In Table I are shown the kinds of bacteria cultivated from 31 air-raid wounds examined at an Emergency Medical Service hospital during 1940. Through the kindness of the surgeons the material examined was collected at operation when the wounds were undergoing their first surgical cleansing. Pieces of the external wounds, wound tracks, and any foreign bodies were taken into sterile Petri dishes from the surgeons' forceps.

TABLE I.—Bacteria obtained from 31 Air-raid Wounds within the First Forty-eight Hours of their Inflection. (*Ps. pyocyanea* and *Proteus* were absent in all cases.)

* No bacteria obtained.

The bacterial population of an early wound is considerable, and small swab samples often yield no bacteria. In order to test larger samples, pieces of excised tissue were either cut up with sterile scissors or ground with sterile glass fragments in a sterile glass hand-mill, and then inoculated into large tubes containing 30 c.c.m. of broth, with or without added sterile blood, serum, or liquid. (Liquid is an anticoagulant which inhibits some of the bactericidal power of normal blood—see von Haebler and Miles (1938).) The necessary manipulation inevitably increased the risk of contamination from the air; stress is therefore not to be

laid on the frequent occurrence of aerobic spore-bearing bacilli and coagulase-negative staphylococci (see Table I), although all possible precautions to prevent contamination were taken, short of working in a bacteria-free atmosphere. Fluid cultures were subsequently plated on to blood-agar plates, which were incubated aerobically and anaerobically. Fragments of the wounds and wound tracks were also smeared direct on to blood-agar plates.

The frequency with which different kinds of bacteria were found among these wounds differed from that observed among older wounds in that pyogenic cocci were rarer while coagulase-negative staphylococci, aerobic spore-bearing bacilli, and *Clostridium welchii* were more common. Six of these early wounds yielded no bacteria. Pyogenic cocci were obtained from three, *Str. pyogenes* and coagulase-positive staphylococci together from one, and each separately from the other two. The wound which yielded both *Str. pyogenes* and coagulase-positive staphylococci was a small scalp wound on the head of a child whose tonsils were large and inflamed. A blood-agar plate culture from the wound eight hours after its infliction gave one colony of *Str. pyogenes*; a few days later Group A streptococci were abundant in both wound and throat. Unfortunately the streptococci from both sources were untypable, but from the evidence it is probable that the wound became infected from the patient's throat, possibly by way of her fingers.

Cl. welchii was found in 8 of the 31 wounds. In one case it produced enough gas and damage in a haematoma around a fractured tibia to lead to amputation. In a second case a piece of metal entered the chest wall, penetrated the abdomen, and lacerated the liver, from a piece of which, excised thirteen hours after injury, *Cl. welchii* was obtained. A pleural effusion subsequently developed in which *Cl. welchii* was present in large numbers, producing much gas. In the remaining 6 cases *Cl. welchii* gave no clinical evidence of its presence.

For comparison, Table II shows the figures for 29 limb wounds of more than five weeks' duration and 13 air-raid wounds of more than forty-eight hours' and less than three weeks' duration, all of which were treated by the closed-

TABLE II

Kind of Bacteria	31 Air-raid Wounds less than 48 Hours Old	13 Plastered Wounds between 48 Hours and 3 Weeks Old	29 Plastered Wounds more than 3 Weeks Old
<i>Str. pyogenes</i>	2	5	20
Staphylococci:			
Coagulase +	2	9	19
Coagulase -	13	5	7
Bact. coli	6	4	15
<i>Ps. pyocyanea</i>	0	1	2
<i>Proteus</i>	0	1	1
Diphtheroid bacilli	3	13	21
Aerobic spore-bearing bacilli	10	2	5
Non-haemolytic and viridans streptococci	5	3	5
Micrococci	6	0	1
<i>Cl. welchii</i>	2	1	1
Other Clostridia	1	1	5
No bacteria	6	0	0

plaster method. Bacteria were much more plentiful in the wounds of these two groups than in the earlier wounds; the cultures from them were made on blood-agar plates, aerobic and anaerobic, and in cooked meat medium.

Discussion

Most of these early wounds were small ones which healed by first intention; their subsequent bacteriology was not followed. Comparison between small wounds which heal by first intention and larger open wounds treated by the closed-plaster method is fair only because there is no

obvious reason why different kinds of bacteria should be carried into them at the time of their infliction. Failure to isolate a given kind of bacterium from a wound is not conclusive proof that no bacteria of that kind were present; on the other hand, the methods of culture employed in this investigation are reasonably sensitive, and the most probable explanation of the failure to isolate pyogenic cocci from more than three wounds seems to be that they were not present in those from which they were not obtained.

Summary

Str. pyogenes and coagulase-positive staphylococci were each obtained from two wounds out of 31 early air-raid wounds examined within forty-eight hours of their infliction. *Cl. welchii* was obtained from 8, of which 6 showed no clinical evidence of its presence. Six of the wounds yielded no bacteria of any kind.

Thanks are due to the six surgeons who kindly allowed the collection of material in their operating theatres, and to Prof. L. P. Garrod for laboratory hospitality.

Medical Memoranda

Narcolepsy

The following is a case of narcolepsy which showed a spontaneous remission of the specific sleep component of the syndrome in eighteen months, and in which the cataplectic component improved but still remains.

CASE REPORT

The patient was a healthy married man, aged 40, who had no previous medical history, and whose personality did not present any evidence of psychopathy. In December, 1939, he was playing at cards under average circumstances when he unaccountably fell asleep. From that date until January, 1941, he became liable to diurnal naps, but, contrary to most recorded cases, he felt no prodromal desire to sleep. The attacks reached their greatest intensity about February, 1940, at which time they averaged three or four a day, each lasting from a few seconds to ten minutes. Simultaneously with the onset of this disability his sleep rhythm, formerly very regular, became disturbed, and though able to get off to sleep early, he would awake frequently, but found no difficulty in going off once again. His dreams, formerly infrequent and neutral, now became very frequent and universally unpleasant, especially those of long-past incidents. The quality of his sleep had no effect on the subsequent day's attacks. Boredom and monotony, intense artificial light as when playing cards, a huge meal, would tend to induce an attack. He never fell to the ground, and in fact was always sitting when the attack occurred, except on one occasion while standing at a lecture, when the losing of his balance woke him up. After an attack he had a feeling of well-being. There was no preknowledge of an impending attack. There were no paraesthesiae, visual or auditory phenomena, or hypnagogic hallucinations. The depth of sleep was "dead asleep," and the waking was instantaneous and unaccompanied by any features of abnormal sensation, behaviour, or thought.

Approximately one month after the above attacks had been established he began to notice cataplectic phenomena. The first of these was a blurring vision "like as if you were to squint," and referable to diplopia. Accompanying this was a sensation which was unpleasant "because it made it awkward to speak," and which was described as a "pulling" of the lower jaw between the angles and the chin. The sensation was analogous to that produced by simulating a risus sardonius. A very short period after the foregoing sensation in the jaw he would "experience a momentary shock" in "all my joints," "just as if you were startled by nearly being run over." The ocular and mandi-

bular sensations were not momentary, and would last "as long as the emotion" provoking them. The provocative emotion was in the majority of instances that of mirth. But certain states of tension, such as "standing in front of an officer" or after "making a difficult billiard shot," had also induced an attack.

The above cataplectic syndrome followed the narcoleptic syndrome in its general progress, but the manifestations of the two syndromes were completely independent, and were dissimilarly provoked and displayed with reference to time. The narcoleptic syndrome had little, if any, effect on his behaviour or personality; but on account of his cataplexy, whereas formerly he had been a man given to mirth and known for his repertoire of amusing, especially salacious, stories, he gradually had to control this tendency until it was completely inhibited. The telling of these anecdotes would invariably precipitate an attack at the climax of the joke. Matinal attacks of hypnagogic cataplexy had occurred in which he had woken up "as in a trance," "continuing with my dream but unable to move until I wilfully woke my body up." There was no history of amnesic episodes. During the period under review he gained 7 lb. and became relatively impotent. Desire remained, but he got a poor erection, and achieved an orgasm with ejaculation with great difficulty. There were no headaches or epistaxis. The patient was of average build, above average intelligence, and free from family history of similar complaints. He had a history of head injury during childhood, when he had had concussion on two occasions. There was no immediate antecedent period of physical or psychic stress. Radiographs of the skull were negative, as were serological tests. Erythrocytes numbered 6,500,000 per c.mm.

The narcoleptic syndrome had made a complete remission by December, 1940, but the cataplectic syndrome, though considerably less, has persisted to date and has not apparently improved with benzedrine.

DISCUSSION

In considering the clinical manifestations of the narcoleptic syndrome, this case may be said to show the majority of the classical features of the illness. To the psychiatrist the most interesting feature was its lack of effect on the patient's personality.

With reference to the relation between the narcoleptic syndrome and epilepsy, it has been pointed out by Daniels (1934) that the dissimilarities outweigh the similarities. Nevertheless, it appears reasonable to assume that the two patterns of neural response overlap somewhat. A much more interesting problem of overlapping is involved when we consider the problem of sleep inclination to certain phenomena of hysteria. At the onset of a fugue it is extremely frequent for the patient to be seized with an overwhelming desire to sleep, and this feeling he usually proceeds to gratify. On awakening—perhaps within an hour, or, if in the evening, some eight hours later—he remains in his disorientated state until, maybe, he comes for treatment. It is unusual for the patient to relate or to know of this fact, and in consequence I can find little reference to it in the literature. The amnesic period of the fugue usually appears to include a short period prior to the sleepiness. Under hypnosis, however, the patient relates all these circumstances. In one patient, who remained in a state of partial disorientation for many weeks, there were recurrent attacks of sleepiness under emotional stress, which all disappeared following treatment.

The neuropsychiatric ground-pattern of hysteria still awaits elucidation, and in a separate paper I have advanced evidence to show a connecting link in the case of the anxiety attack with known lesions in the region of the third ventricle. Here again in the topic under discussion is a symptom (a feature also in many hysterical fugues) which occurs in a setting the organicity of which is not open to doubt and whose site of production appears to be in the neighbourhood of the third ventricle. Finally, it appears justifiable to refer to the disturbance of nocturnal sleep rhythm and impotence, which are two cardinal features in involuntional melancholia and which occur in the syndrome here recorded.

Reviews

MAGIC AND SCIENCE

A History of Magic and Experimental Science. Vols. V and VI. By Lynn Thorndike, Professor of History, Columbia University. The Sixteenth Century History of Science Society Publications, New Series IV. (Vol. V, pp. 696; Vol. VI, pp. 766. 6s. 6d. net two volumes.) New York: Columbia University Press. 1941.

The fifth and sixth volumes of Prof. Lynn Thorndike's *History of Magic and Experimental Science* contain more than 1,400 pages, the index cites some 1,700 topics or names of things and more than 3,000 names of persons. These volumes are concerned with the sixteenth century. Science is defined by Prof. Thorndike as "systematical and ordered knowledge, a consistent body of truth, attained through sense perception, introspection, and reflection, aided by mechanical and mathematical instruments, independently of faith, emotion, prejudice, appetite, pleasure, and the like." Magic, on the other hand, "was a systematized and ordered marvel-believing and marvel-working, a consistent body of error, attained through sense perception, introspection, reflection, and dreaming, influenced by faith, emotion, appetite, and pleasure, marked by unwarranted associations of ideas, without adequate means of correcting error and without proper standards of measurement." A logician might doubt whether if a body of error were wholly self-consistent it could properly be described as error, but, for practical purposes, the antithesis may stand.

The field of human thought and speculation covered by Prof. Thorndike is so vast (he does not include pure mathematics, but astronomy and medicine are within his connotation of experimental science) that a book planned to include some reference to all the significant writers cannot avoid a certain dryness. Judicial astrology, for instance, treated as a game (one recalls the classical instance of Colonel Mannerling) the rules of which were much more complicated than those of chess might well be as interesting as cross-word puzzles. But unless the reader (unlike the present reviewer) knows the rules and how they were modified by different players, succinct accounts of the conclusions reached by A, B, and C seem not amusing and ingenious nonsense but just plain and dull nonsense. The same remark applies to other departments of magic.

A medical reviewer inevitably turns to the chapters describing men famous in medical history or the history of the sciences fundamental or ancillary to medicine. These volumes naturally include such illustrious names as Leonardo da Vinci, Vesalius, and Fracastoro. In reading Prof. Thorndike's accounts of these revered investigators, and comparing them with those of contemporary scientific historians who were primarily interested or trained in the subject-matter of their historical researches, one is conscious of a change of emphasis. The scientific writer emphasizes the intimations or realizations of what we have come to regard as important truths and ignores or passes lightly over imperfections or errors which link the pioneer with his contemporaries. The pure historian, more interested emotionally in the men and their *milieu* than in the object of their scientific inquiries, does just the reverse. Prof. Thorndike is much more concerned to point out the imperfections of da Vinci and the others, how much they were indebted to predecessors, how often they shared superstitious beliefs with less gifted contemporaries, than to expatiate on their highest qualities. He does not obey Steerforth's exhortation to David Copperfield—"Think of me at my best."

Prof. Thorndike in a footnote (vol. v, p. 493) comments with some asperity on the neglect of Meunier, Prof. W. C. Wright, and Prof. and Mrs. Singer to associate Fracastoro's treatise on sympathy and antipathy with his book on contagion. "Such is the way," he writes, "that we 'gloss over our Augustine' and refuse to view the past as it really was." To the scientist, the fact that Fracastoro did have an idea of *contagium vivum*, of a biological process, wholly unlike the idea of contagion present in the minds of his predecessors (to whom contagion was not a process perpetually reborn in a chain of biological events, but rather akin to the passage of a note from tuning-fork to tuning-fork) was Fracastoro's peculiar merit. It was natural to turn a blind eye to his imperfections, to forget, for instance, that he hesitated to push his theory to its logical conclusion and did not think it adequate to explain the pandemic diffusion of syphilis. This is, perhaps, only another way of saying that the two classes of writer had different objects. If we wish to know which of our predecessors had reached truths which later experience has proved to be important, men of science whose historical studies are *parerga* are better guides than professional historians. If we wish to know what the general state of knowledge and belief in a bygone age really was, the trained historian will be a better guide. If time permits we should read both. Prof. Thorndike's view of sixteenth-century culture is a cure for regarding that period as a golden age. It almost, but not quite, reconciles us to the age in which we live.

CHROMATOGRAPHY

Principles and Practice of Chromatography. By Prof. L. Zechmeister and Dr. L. Cholnoky. Translated from the second and enlarged German edition by A. L. Bacharach, M.A., F.I.C., and F. A. Robinson, M.Sc., F.I.C. With a foreword by Prof. I. M. Heilbron, F.R.S. (Pp. 362. 25s. net.) London: Chapman and Hall, Ltd. 1941.

The technique of chromatography was first devised by a Russian botanist—Tswett—of whom nothing has been heard since the last war. His work was published in various scientific journals between the years 1899 and 1912. It received recognition in this country in 1924 with some slight development, but only when the relation between vitamin A and carotenoids became apparent was the technique fully appreciated. Then followed a flood of work both in this country and on the Continent which could only have been made possible by chromatography.

In its simplest form the process is this. A test tube with perforated end is fused to a short length of narrow glass tubing, plugged at the lower end with cotton-wool, and evenly packed with some adsorbent such as dry calcium carbonate or aluminium oxide to a depth of four to five inches, leaving an inch or two of the test tube unfilled at the top. A solution of a mixture of nearly related substances is allowed to filter through it, hastened by suction, and the various substances are adsorbed at different levels of the column. The whole column is pushed out of the test tube by a rod passing through the glass tubing and cut into sections corresponding to the different layers of substances visible in it. These are eluted separately and the different components of the original solution thereby separated. The process may be designated fractional adsorption.

The first part of Zechmeister and Cholnoky's book on this subject deals with the principles involved in the process, the relation between chemical constitution and behaviour of a substance on the chromatogram. The actual method is described in great detail with many practical hints for the successful carrying out of the delicate technique.

Numerous modifications in apparatus, adsorbents, and solvents for adaptation to particular problems based on the authors' wide experience are given. The second part of the book deals with results already obtained in the separation and purification of substances of very many different types: chlorophylls, carotenoids, anthocyanins, azo-dyes, and even colourless substances such as terpenes, aromatic hydrocarbons, and sterols, many of which disclose their presence in the chromatogram by fluorescence when subjected to illumination by the quartz mercury vapour lamp. There is a bibliography of some 600 references (the contents of which are not always correctly quoted) and 74 figures, of which 24 are excellent reproductions of photographs of chromatograms, others of photographs of apparatus, others clear pen-and-ink diagrams.

The book will be received with delight by everyone using this technique and by others who have not already used it but may be stimulated to try to apply it to their own particular problems. The translators are to be congratulated in that it is difficult to realize that this is indeed a translation.

A LEPER'S LIFE

Who Walk Alone: The Life of a Leper. By Perry Burgess, President of the American Leprosy Foundation. (Pp. 318; illustrated. 12s. 6d. net.) London: J. M. Dent and Sons, Ltd. 1941.

In spite of the continuous research that leprologists all over the world are giving to the nature and control of leprosy, much still remains obscure. Great devotion in dealing with it has been shown by doctors and nurses, sometimes at the cost of their own lives. Dr. Perry Burgess, the author of *Who Walk Alone*, has been National Director of the American Committee for the Eradication of Leprosy since 1925. He conceived the idea of laying bare the soul and all the human emotions of a leper by writing the life history of a United States soldier who became infected during the Spanish-American war in the Philippines. Over thirty American soldiers developed leprosy years after their return from that campaign.

The book is a soul-stirring tale, highly dramatic, poignant, and powerful in its appeal for a closer understanding of the subject of leprosy. It is cleverly written and can be read with profit by medical men and laymen alike. One follows the life story with breathless interest to the very end and lays down the volume with a great feeling of gratitude to the author for having presented his subject in such a moving way. From the book we gather that there are 3,000,000 lepers in the world, and the most heavily affected areas are in East and South Asia, particularly China and India, Malaya, Africa, and parts of South America. The British Empire Leprosy Relief Association is the counterpart of the American committee, which is directed by Dr. Burgess.

Notes on Books

John Wright and Sons, Ltd., of Bristol now publish an eighteenth edition (making the 215th thousand) of *Warwick and Tunstall's First Aid to the Injured and Sick*, which has been a favourite ambulance handbook for forty years. Its preparation was entrusted to Major Norman Hammer, to whom first aid for air-raid casualties has been a principal interest for the past five years. Both text and figures show evidence of full revision; Part II, forming three-quarters of the book, has in fact been largely rewritten. Major Hammer explains in the preface that his aim has been to preserve the characteristic features of the work, bearing in mind that this is a handbook of general first aid; at the same time he tries to show how the application of

general principles should be modified, and procedures simplified, according to the special needs of wartime first aid both to casualties in the Services and to victims of air bombing. The price of the book is now 3s. 6d., and it will no doubt have a ready sale.

Dr. DONALD PATERSON has extensively revised his *Sick Children: Diagnosis and Treatment* for its fourth edition. A great improvement has been achieved by transferring a mass of detail on dried milk and proprietary foods to the appendix, so that the whole subject of infant feeding now collected into three chapters is treated in a more balanced fashion than hitherto, with a satisfactory emphasis on normal breast-feeding. The chapters on nephritis, nervous diseases, blood diseases, and the endocrines have been revised, and that on tuberculosis is completely new. All these changes have improved what was already recognized as an essentially practical guide to paediatrics of a solid and reliable standard. But there is little indication that the child has a mind as well as a body, and the relative lack of any detailed discussion of psychological disturbances of childhood is not in accord with modern developments. This edition is larger than its predecessor, and contains more illustrations and eight new plates. It is published at 15s. by Cassell and Company, Ltd.

Preparations and Appliances

DEVICE FOR WASHING CONTAMINATED EYES

Dr. J. L. BARFORD (Redhill, Surrey) writes:

I enclose a drawing of an exceedingly simple device, "cribbed" from the bottles in which petrol-lighter fluid is sold, which enables every carrier of a Service water-bottle—especially, of course, stretcher-party personnel—to have ready at hand the means for washing out eyes contaminated by liquid "mustard," etc.

It consists of an ordinary cork (c), of about the same size as that of the water bottle, through which pass (a) a short length of rubber tubing of about ordinary douche-can diameter, (b) a very small glass tube (but this can be dispensed with, a hole being merely bored through the cork). The length of rubber tube is so short that it cannot injure the eye, and the water bottle is conveniently steadied against the patient's head.

This spare cork is best kept in a small envelope of calico or such-like, with press-button fastener, tied on the outside of the water bottle. The cost is about 2d.

ELECTRIC HEATERS IN SURFACE SHELTERS

An interesting type of electrical heater is being fixed in the Liverpool communal surface shelters at the instance of the city electrical engineer. It consists of a concrete box or cover containing a heating element. The box is arranged to bolt, where possible, to the outside shelter wall and sit over an air brick, thus ensuring a fresh air supply in addition to warmth. The concrete cover provides a cheap and effective protection for the heating unit and it operates at a low temperature and can safely be touched. The loading of the heating element, which may be of any type, can be varied to suit requirements. Loadings of 200, 500, and 1,000 watts are arranged in a 12-in. box, and of 2,500 watts in a 24-in. box. The system of protected wiring employs a homogeneous tough rubber. Cement is moulded round the cable where they drop down to the heaters. This method of wiring has the advantage of simplicity, cheapness, and protection from all except malicious and wilful damage. The concrete heater box complete with element costs £1 13s. 6d. in the 12-in. and £2 15s. 6d. in the 24-inch size.

SATURDAY OCTOBER 4 1941

HEAD INJURIES IN MOTOR-CYCLISTS

During the first two years of war the number of road fatalities in this island amounted to little short of 20,000. In all varieties of road users, except adult pedestrians, the statistics published by the Royal Society for the Prevention of Accidents show a steady increase in the numbers killed, and in motor-cyclists the increase last winter was 50% as compared with the previous winter. For the last four months of 1940 on an average five motor-cyclists were killed each day; the distribution between civilians on the one hand and the fighting Forces on the other was approximately equal. As to the number of motor-cyclists temporarily or permanently incapacitated by accidents which are not fatal, no figures are available, but there can be little doubt that there is a considerable drain of man-power from this cause. Before this war the Ministry of Transport returns showed approximately: twenty-five motor-cyclists injured for each one killed.

The only effective way of preventing accidents is to encourage careful driving, and this is particularly necessary in motor-cyclists, for it seems that the motor-cycle gives a more exhilarating sensation of speed than any other motor vehicle, not excluding the aeroplane, and in collisions the rider is quite unprotected. Motor-cyclists are for the most part young men, a group to whom caution on the roads does not come easily. The measures so far taken to instruct people in the use of the road have doubtless done good, but they have not prevented an appalling and ever-increasing waste of life, and there is a strong case for a further inquiry on scientific lines to collect information as to the amount of incapacity which results from motor-cycle accidents, to study means of alleviation and prevention of accidents, and to revise the methods of educating motor-cyclists in road sense and the use of their machines.

In this issue of the *Journal* Prof. Hugh Cairns reports some investigations on motor-cycle accidents. He finds that head injury was present in over 90% of a large series of fatal accidents. In some cases the head injury was not severe enough to cause death, but multiple injuries were present in two-thirds of the cases, and the combination of two or more injuries each of which by itself would be non-fatal can suffice to cause death. If the head injury could be alleviated a considerable number of these cases would not be fatal. The Army has taken an important step in this direction in providing its motor-cyclists with crash helmets of the type used by dirt-track riders before the war. It is too early yet to assess accurately the value of this protection, and it may be difficult ever to obtain properly controlled statistics, but the cases reported by Cairns are encouraging. He describes seven cases and mentions a further eight in which Army motor-cyclists were wearing

crash helmets at the time of the accident. In several of these cases the violence to the head was sufficient to produce gross fracture of the crash helmet, but in all cases the damage to the skull and brain was slight. Further experience may establish the need for making the use of a crash helmet compulsory not only for soldiers on duty but also for members of the other fighting Services, soldiers on leave, and civilians. Meanwhile there is doubtless work to be done in improving the types of crash helmet in use, and this is a problem which we may be sure is engaging attention.

Cairns gives figures to show that fractures of the lower limb are particularly prone to occur in motor-cycle accidents, and the number of such cases requiring prolonged treatment is likely to increase if lives are saved by means of the crash helmet. Protection of the legs from injury is a much more difficult problem than that of head protection, since it would entail alteration of the design of motor-cycles and the addition of more weight to the machine, a step which might not find favour with manufacturers or with those who wish to attain high speed on the road. But there are already in existence some types of machine which provide leg protection, and the problem of converting other types should not be insoluble if the case for it can be clearly established and if sufficient pressure can be brought to bear on the manufacturers. This is a matter in which surgeons should take an active part: it is more effective to prevent or alleviate limb fractures than to treat them well. But no amount of protection to head or limbs will prevent fatalities when accidents take place at high speed, so in the last analysis the best preventive measure of all is thorough education in careful use of the road.

MEDICAL STATISTICS IN WARTIME

On September 17 Sir Wilson Jameson said that "at the close of this second summer of the war we had every reason to be thankful for the health of the country," but added that "local authorities and the medical profession must remain on the alert." Sir Wilson briefly reviewed good and less good features of our experience: among the former, the saving of young lives through evacuation and a decline of cerebrospinal fever; among the latter, the prevalence of paratyphoid infections and some increase of mortality from tuberculosis among young women.

So that local authorities and our profession may remain effectively on the alert they should be well informed, and they are less well informed than during the war of 1914-18, when the publications of the General Register Office were continued. Now unofficial students of mortality rates are vouchsafed hardly any information. No complete data for any year later than 1938 have been published. In the last war, as in this, the death rate from tuberculosis increased among young women, and various explanations were suggested—for example, the increased employment of young women in factories. The late T. H. C. Stevenson showed this explanation to be inadequate because an unfavourable trend in this age group antedated the time when large-scale employment could have been a factor; and, after the war, the trend continued to be unfavourable for

several years and has been the subject of research by Bradford Hill, D'Arcy Hart and Payling Wright, and others. Although fresh light has been thrown on the subject by these investigations, the general problem is still unsolved. The conditions of the present war differ in important ways from those of 1914-18 and a new field of investigation is opened; it cannot be cultivated unless workers are allowed to enter it.

It has been suggested that if detailed information were made public it would be of military value to the enemy. Two hundred years ago the House of Lords rejected a Census Bill on that account; exact knowledge of populations was regarded as a military secret by some Continental nations much later. But the enemy now has all our official publications down to and probably including those relating to 1938. Without any more recent information, by the use of common sense and elementary statistical methods he can estimate, and no doubt has estimated, the numbers living in Great Britain in all age groups from 5 to, say, 65 with an accuracy sufficient for any conceivable military purpose. There is, however, a more rational objection to the use of death rates on males. It has long been the practice to give specific rates of mortality in terms of the civilian population. Before 1914 the exclusion of the armed Forces was of trivial importance, but in 1914-18 it deprived the rates on males of any value as public health indices, because, *inter alia*, the denominator of the rate had lost a large proportion of the physically fittest men, so that rates of mortality were unreasonably high. It was necessary to use rates on women alone as indices. This objection is still valid. Unless *all* deaths (by causes and in age groups) are related to the relevant age groups of *all* males observed in Great Britain the rates on males will be of little value. There is no obvious reason why the mortality rates of women should not be as informative as in 1914-18 provided that the deaths of women drafted into the fighting Services are included in numerators and the whole populations taken as denominators.

Wholly apart from the fact that secrecy prevents discussion which might throw light on aetiology, it inevitably encourages rumour and exaggeration. One of the evils of war is unavoidable secrecy; it is important not to increase this evil by needless mystery. The Annual Reports of the General Register Office were not studied by as many medical men as we could wish, but they were, directly and indirectly, the most potent educational instruments forged by the central Government. We know of no adequate reason why the medical profession should be deprived for the duration of the war of means of testing the success of its work.

SPREAD OF ACUTE INTRAPERITONEAL EFFUSIONS

The spread of acute intraperitoneal effusions is of immediate and practical interest to all abdominal surgeons, and a knowledge of the natural history of such effusions has important bearings upon the questions of diagnosis, operative treatment, and post-operative complications. The experimental investigation of the various intraperitoneal watersheds and clinical observation at operation have to-

gether provided most of the accurate data upon the subject. Recently Mitchell¹ has carried out further experimental work and has put forward some new evidence and views relating to the spread of intraperitoneal effusions from the region of the right subhepatic space. When the body is in the supine position there are three main abdominal barriers which act as watersheds. The first is the longitudinal barrier formed by the bodies of the lumbar vertebrae, covered by the great vessels and the mesentery of the small intestine. This divides the peritoneal cavity below the level of the transverse colon into right and left infracolic spaces, but, owing to the obliquity of the mesentery of the small intestine, these are not symmetrical. The second barrier is the upper transverse one formed by the transverse colon and mesocolon. The third is the lower transverse one formed by the posterior part of the pelvic brim, covered by its muscles and great vessels. The supracolic space can be further divided into the right and left subphrenic spaces, the right subhepatic space (Morison's pouch), and the left subhepatic space or lesser sac. The other principal spaces are the right and left infracolic and the pelvic space.

The generally accepted routes of spread of fluid from a perforated duodenal ulcer, a perforated posterior-wall gastric ulcer, an anterior-wall gastric ulcer near the pylorus, or from a perforated gall-bladder, are as follows. The fluid fills the lesser sac or the right subhepatic pouch and spreads upwards to the right subphrenic space or extends along the right paracolic gutter. It then passes into the pelvis, and when enough has collected here it wells up into either infracolic space, or it may pass into the left paracolic gutter and reach the perisplenic space. Mitchell's experiments were carried out on the bodies of stillborn infants, and fine barium emulsion was injected into the peritoneal cavity through a small perforation on the posterior wall of the stomach. Radiographic examinations were carried out at various stages of the injection, and at the completion of this the findings were checked by dissection. As a result of these experiments it was found that the spread of intraperitoneal barium emulsion did not correspond to the description which has already been given and which is the generally accepted one. Mitchell found that fluid collected in the right subhepatic space, and then overflowed into the antero-internal angle of the right subphrenic space, usually through the quadrangular interval bounded by the quadrate lobe of the liver, the gall-bladder, the falciform ligament, and the transverse colon. At this stage, however, the main part of the right subphrenic space was not invaded, but the fluid spread downwards and to the right in front of the transverse colon and around the margin of the great omentum, and so reached the right infracolic space. From here some of the fluid flowed over the ascending colon into the lower part of the right paracolic gutter, and some of this then extended upwards and entered the right subphrenic space. Part of the fluid from the right infracolic space passed in front of the ileo-caecal junction, entered the left infracolic space, spread throughout this, and extended upwards into the left subphrenic space and downwards into the pelvis. The pelvis may also be invaded by a trickle which runs round the lower margin of the caecum from the paracolic gutter. But it was noteworthy in these experiments, which were carried out in the recumbent position, that the pelvis remained free from fluid at a relatively late period.

From these new experiments three principal facts emerge: first, that there is no direct spread of fluid from the right subhepatic space to the right paracolic gutter; secondly, that the pelvis is chiefly filled by fluid overflowing from

¹ *Brit. J. Surg.*, 1940, 28, 291.

the infracolic spaces; and, thirdly, that there is little evidence that fluid spreads from the pelvis along the left paracolic gutter to the left subphrenic space. It is not, however, any criticism of these careful observations to point out that experimental conditions are very different from those which may be present in the living human being with an acute inflammatory intraperitoneal exudate. Under clinical conditions the patient is not always or entirely supine; he may not remain quite motionless; abdominal rigidity may be present; and intestinal distension or inhibition may be an important modifying factor. All these factors may play a part in determining the spread of intraperitoneal fluid, especially from the region of the right subhepatic pouch, and experimental observations cannot be translated too readily into clinical dogmatism. But these new views should prove a stimulus to further clinical observation by all who operate on acute abdominal conditions.

AN AMERICAN DOCTOR ON THE WAR

Dr. David Cheever, President of the American Association of Surgeons, in his presidential address¹ on "Mars and Aesculapius," delivered at White Sulphur Springs on April 28, paid tribute to the fact that 83% of the Fellows of the Association volunteered for the last war, and gave details of the part played by the American medical profession in general. On the subject of the present war it is worth quoting his remarks: "With our weight tilting the scale the war was won, but the peace, it seems, was lost, for now, scarcely a score of years later, we stand again at the gates of Armageddon. Our idealism in undertaking to ensure the future of democracy by waging a war to end war has become a mockery. The same enemy confronts us, his purpose far more sinister, his strength vastly augmented by the devotion of the whole wealth and power of a great nation for the sole purpose of ruthless aggressions, his resources multiplied by those of the peace-loving, terrorized, conquered peoples; his mailed fist supported by allied ghouls whose nostrils tell them—falsely, to be sure—of the expected kill. More dangerous is he because of his strength, but also because of the doctrine with which he has inoculated the people—a doctrine at once ludicrous, absurd, but dreadful in its evil intent, of a superior race predestined by the Creator to prosper at the expense of all other peoples. This foe is bending all the agencies of the physico-chemical and physiologic sciences to his purpose, and showers death in its most ghastly forms on man, and destruction on the monuments of his civilization to a degree which is callously designed to involve a nation in its totality if it refuses to submit. The unarmed, the defenceless, the weak, the aged, the young of either sex have no privilege of even partial exemption, but rather suffer the more because they have not the strength for self-defence. And, standing rock-like against this monstrous, reckless, merciless destroyer stands the English-speaking island Empire and her overseas daughters, shorn by enemy subjugation of all her allies save one, making us to consider whether a precarious freedom can be enjoyed alone in case of her defeat." He then goes on to discuss, without pronouncing on their validity, the theories of the opportunity for medical development in war as opposed to peace, and from the historical and scientific point of view traces them from their origins. His epilogue ends thus: "Again Britain and her daughter nations, bleeding but with heads unbowed, stand against this monstrous thing. Again America is moving to her side; again the weight of her power will press down the scale pan wherein lie liberty and

justice. When the victory shall be won, let our care be that mankind shall also win the peace by lavishing on its nurture something of the same energy, treasure, and self-sacrifice which is poured into the lap of Mars." These words of Dr. Cheever's come as a high encouragement to us on this side of the Atlantic.

EUMYDRIN FOR PYLORIC STENOSIS

Dr. Helen Mackay has recently² given a detailed analysis of the treatment of forty consecutive cases of congenital hypertrophic pyloric stenosis with eumydrin (atropine-methyl nitrate), and it would seem a suitable time to consider whether or not this method should replace surgery for this condition. All but two of the series were treated as in-patients, the diagnosis in every case included the palpation of a thickened pyloric "tumour," and the average stay in hospital was between three and four weeks. Of the forty patients, five died during the treatment, one of enteritis and pneumonia some weeks after going home, and a seventh died also after discharge. On the basis of five deaths the mortality is given as 12.5%. Actually thirty-one babies were "cured" by eumydrin alone and a fourth by operation when eumydrin had proved unsuccessful. The general management and feeding of these babies has undergone some evolution in the light of experience, and it is more profitable to summarize Dr. Mackay's considered recommendations than to set out the reasons for and against gastric lavage, extra fluid, frequent feeds, and so on.

The routine suggested is as follows. Unless obviously dehydrated the baby is given fluid by mouth only, amounting to 3 oz. per lb. body weight (inclusive of foods), in the first twenty-four hours, and thereafter only such extra water as he will take readily. Breast-feeding should be continued if possible, three-hourly for six feeds in the twenty-four hours being best, with a sweetened condensed milk diluted 1 in 5 by volume to give 20 calories per ounce as a substitute. Full caloric requirements should be reached within two or three days of starting treatment. If feeds are vomited they are not repeated. Freshly prepared eumydrin (1 in 10,000) not more than a week old is given half an hour before each feed, beginning with 0.5 to 1 c.cm. and increasing by 0.5 c.cm. each feed up to 2.5 or 3.0 c.cm., or even more if necessary. No gastric lavage is recommended. If abdominal distension occurs the dosage of the drug and the food intake are reduced. If the treatment fails the drug is omitted for twenty-four hours before operation. After a varying period, probably two to three weeks, a gradual reduction in the dose of eumydrin can be started and the drug eventually discontinued. This routine could be followed by any intelligent mother at home after a period of instruction, possibly as an in-patient with the baby for a limited period. For it is on the question of prolonged stay in hospital that the drug treatment of pyloric stenosis offers greater dangers than operation. Dr. Mackay claims a mortality of 11.5% for eumydrin treatment of 122 cases published in this country, including a series of forty cases with five deaths recently reported by R. H. Dobbs,³ and sets against this a general mortality for surgically treated cases of about 25%, hinting that this is achieved only by special teamwork and may be more in areas where surgeons experienced in the operation are not available. This is hardly fair, for Dr. Mackay's results appear to have been achieved by "anxious work" (her own words) by the sisters and nurses of the hospital, and

¹ *Ann. Surg.*, 1941, 113, 881.

² *Arch. Dis. Child.*, 1941, 16, 1.

³ *Lancet*, 1941, 1, 661.

on the other hand, closely co-operating "teams" have published results from surgery which are better than the eumydrin series, such as those from St. Bartholomew's Hospital with one death in fifty consecutive infants, as reported by C. F. Harris and G. Keynes.² In these columns recently D. Levy³ reported a series of 100 consecutive operations on breast-fed infants with pyloric stenosis without a single death. Out of forty-six bottle-fed infants operated on five died. Levy insists that statistics of results from medical and surgical treatment cannot be compared in the absence of full information on the method of feeding.

The crux of the whole matter is summed up by Dr. Mackay in the statement: "It is notorious that in cases of pyloric stenosis treated in hospital the biggest cause of mortality is often infection acquired in hospital." Hence the claims of surgery over drug treatment to shorten the period of stay in hospital have strong adherents. There would seem to be two ways to move on from the present position if operation is to be avoided. The first is for improved hospital construction and routine, whereby infection can be avoided. What, for example, are the results of treating pyloric stenosis going to be in the new building at the Hospital for Sick Children, Great Ormond Street? The second is for a wholesale test of Dr. Mackay's suggested routine with all the babies as out-patients for most, if not all, of the time required for treatment. In this connexion a rather less vague end-point for the use of eumydrin is desirable. Wartime conditions may make for some delay before further progress is achieved. At all events the use of eumydrin is now clearly established and the details for best results are plain. There is no need for sterile controversy. Advocates of surgery on the one hand and of eumydrin on the other can go on working at their respective methods until time proves what is really best in all the circumstances for the young infant suffering from pyloric stenosis.

SURGICAL TREATMENT OF PARKINSONISM

We are apt to forget the trials of peace amid the trials of war, and naturally exert ourselves to solve the immediate acute medical problems which confront us. But the peace-time diseases still remain to be treated, and of these paralysis agitans is surely a disability which calls for all possible help, even if this is only palliative. In the past treatment has been medical, the stand-by being atropine and allied drugs. It is recommended in enormous doses, alone and with other antispasmodic drugs. As in other conditions which resist treatment the therapeutic agents are legion, the vogue for the newer ones usually being short-lived. There is little reliable evidence that the Bulgarian treatment is better than any other; the reports of carefully controlled experiments have shown its efficacy to be identical with that of the more usual tincture of belladonna. Putnam has for some years been trying to improve the distressing tremor of paralysis agitans by surgical methods. Three years ago⁴ he reported that section of the anterior column of the spinal cord, which effectively diminishes athetoid movements, did not affect the Parkinsonian tremor in five cases. Puusepp⁵ cut the column of Burdach, with improvement of the tremor, and Bucy and Case⁶ extirpated the motor and pre-motor cortex on the opposite side with some relief of the tremor. Putnam⁷ has extended his work, and now reports on the effect of excision of appropriate areas of the motor cortex and of section of the pyramidal tracts of the spinal

cord. He selected for operation ten patients with very severe disabling unilateral tremor. He found that, although the results of cortical excision were disappointing, pyramidal section in the cord produced considerable relief of symptoms, and supports his claim with electromyograms, photography of the degree of disablement before and after operation, and by samples of handwriting. Of course a spastic hemiplegia results from the pyramidal section, but the degree of spasticity depends on the completeness of the section, and unfortunately the improvement in the tremor also seems to be related to the amount of pyramidal involvement; but, as Putnam observes, it is much less disabling to have a mildly spastic arm which can be used for limited movement than to have continuous rhythmic movements which cannot be controlled. He records that his patients were grateful for the relief obtained. Putnam also points out that his results are at variance with the results of physiological experiments, notably those of Aring and Fulton⁸; but he considers that Wilson's conception⁹—that the tremor of paralysis agitans is due to dysfunction of extrapyramidal pathways—may be incorrect. He thinks that the abnormal rhythmic discharge is conveyed to the muscles by the pyramidal tracts. Whatever the physiology of the condition, bilateral pyramidal section will indeed be heroic treatment, but little short of this would be required to relieve the majority of the severe examples of paralysis agitans encountered in hospital practice, for unilateral severe Parkinsonism is uncommon.

A WEEK-END OF WAR MEDICINE

During the last week-end of August, at a military hospital (writes a correspondent), there gathered a dozen near-by R.M.O.s for a postgraduate refresher course. For a long time the need for closer liaison with the more "forward" officers has been felt; at the same time the desirability of sharing the immense clinical material of the hospital with others not so fortunately placed was evident. On Saturday afternoon the O.C. welcomed the "students" and spoke of the work of a general hospital. The experience of the hospital at home and abroad was illustrated from records. The startling difference in the type of admission on active service and in quiescent periods gave much food for thought. "Every hospital," he added, "should be a centre of medical culture, and now that so many of the staff of teaching hospitals were doing duty in military hospitals these should not any longer be exceptions." This week-end course, he hoped, would be only a beginning. The physician then led off the clinical rounds. Several "short" and two "long" cases were shown—a streptococcal fever (with a digression on recent work in dust infections) and a case of multiple nutritional deficiencies. The dispenser demonstrated the B.L.B. oxygen apparatus. The surgeon had a large variety of common and uncommon complaints in his wards, and, as luck would have it, the first case of gas gangrene the hospital had admitted in home territory. The radiologist produced one film after another from a seemingly never-ending store. Most interesting was a series of films of cases of pulmonary tuberculosis from the earliest lesion to advanced fibro-caseous pulmonary tuberculosis with cavitation. Sunday morning was devoted to the psychological problems that bulk so large in regimental practice. The physician discussed the modern integration of hypothalamus, emotions, autonomic system, endocrines, and cerebral cortex. The mechanism of psychosomatic disorders was illustrated from the physiology of the stomach and clinical

work on peptic ulcer. The psychiatrist dealt with neurosis in soldiers, the chronic problems and the more acute ones, such as occurred, for example, at Dunkirk. He showed two cases—a conversion hysteria and, as postscript, an imbecile. As a fitting conclusion the assembled medical officers did the progressive matrix intelligence tests on themselves, and the absence of mental deficiency was a matter for mutual congratulation. In the afternoon the specialists took the field: there was a demonstration of scabies, impetigo, ringworm, and the newer methods of treatment (non-fatty bases and sulphanilamide ointments) that were being tried. The importance of personal hygiene was again and again emphasized. The ophthalmologist's subject was "Eyes, injuries to, and bodies, foreign, in." He also dealt with gas burns and the albucide treatment. Finally, in an open discussion, the talk, as seems inevitable when R.A.M.C. officers meet, was mostly of the problems of mental health in a nation mobilized for total war and the immense responsibility resting on the Corps. The O.C., in a closing greeting, extended the freedom of the hospital to all the medical officers and expressed the appreciation of the hospital staff for their never-failing co-operation.

THE CHEMISTRY OF THYROID DISEASES

The popularity of the basal metabolic rate in the investigation of thyroid disorders during the last few years has perhaps had the effect of limiting interest in other chemical abnormalities in such conditions. The results of certain liver-function tests have already been discussed here,¹ but there are in addition many observations on creatine, lipid, and iodine metabolism which may finally become of clinical importance. Creatinuria has been long recognized as a feature of hyperthyroidism, and there is also a correlation between creatinine excretion and the basal metabolic rate (Palmer, Means, and Gamble²). Recent reports, however, suggest that the incidence of creatinuria among normal subjects is greater than at first supposed (Hobson³) and is perhaps sufficient to reduce the value of the estimation as a diagnostic procedure. The relation between the basal metabolic rate and creatinine excretion in hyperthyroidism is also not close enough to encourage further work on these lines at the moment (Bröchner-Mörtensen and Möller⁴). An inverse relation between blood fat content and thyroid activity has been apparent since the work of Denis.⁵ Either the total fat or the cholesterol determination has been used, and both the fall in hyperthyroidism and the rise in myxoedema have been found of value by some workers (Nicholls and Perlzweig,⁶ Hurxthal,⁷ and Green⁸). While these procedures are often useful as confirmatory tests, the wide range of values causes a certain amount of overlapping in the two conditions. Iodine metabolism, while obviously of fundamental importance in view of the structure of thyroxine and of the therapeutic effects of iodine, has so far contributed little to diagnosis. This is no doubt because of the great chemical difficulties in estimating very minute amounts of iodine variously combined. Elmer's work⁹ is outstanding in this field, and it appears from this that the total blood iodine (8-20 microgrammes per 100 c.cm.) is of little

clinical value. Blood thyroxine has been investigated in a few cases, but large volumes of blood are required and the estimation is tedious and not entirely specific. It is certain that technical improvements in this field would have an enormous influence on the whole question of hyperthyroidism, the very definition of which is at present a matter of opinion. If the word is to have an exact meaning it should mean an increased amount of thyroid hormone in the blood, and when the direct demonstration of this is possible as a routine a major advance will have been made.

COMMITTEE ON NURSING SERVICES

Early in 1939 it seemed that at last some radical improvements would be made in the terms and conditions of service of nurses and, with a view to better recruitment, in the status of the profession in the public eye. The Inter-departmental Committee on Nursing Services, of which Lord Athlone was chairman, had recommended fundamental changes, and the Government showed every sign of being prepared to act upon many of the recommendations. Unhappily for the nursing profession and for those outside it who have for years striven against the placid acceptance by the public of almost nineteenth-century conditions of service for nurses, the outbreak of war put a stop to any considered action on the lines of the committee's report. The Royal College of Nursing, however, has now shown that it is not content to await the end of the war before preparing the ground for these and other much-needed reforms, and has set up a committee to consider ways and means of carrying out some of the recommendations and to plan for the future. Actually the decision to establish this committee was taken earlier this year, but it was not then thought expedient to do more than appoint a small subcommittee to examine the most urgent problem—the control of the assistant nurse. The first report of this subcommittee will soon be ready, but in the meantime the College has decided to proceed to the larger task of examining all other problems and of preparing for post-war reconstruction. Half the main committee, of which Lord Horder is chairman, are to be members of the Royal College of Nursing; the other half are to be representatives from the British Medical Association, the Medical Women's Federation, the British Hospitals Association, the National Association of Local Government Officers, the County Councils Association, the Society of Medical Officers of Health, the County and County Borough Hospital Matrons' Association, and the Association of Hospital Matrons. The Council of the B.M.A. at its last meeting accepted the College's invitation to be represented, and appointed Dame Janet Campbell, M.D. The many schemes already put forward for the improvement of nurses' training and conditions of service will be examined by the committee, whose final recommendations should represent an agreed policy acceptable to all parties, not least to the nurses themselves.

We have received a stencilled document entitled "A Report on the Possible Relationship between Electrical Equipment and the Incidence of Anterior Poliomyelitis," by James G. Woolley, with a foreword by Harlan Shoemaker, M.D. This report contains statistical evidence which leads the author to believe that the incidence of poliomyelitis has an aetiological relation to the lay-out of high-tension electricity in the City of Los Angeles. The author's presentation of the data is not very easy to follow, but his researches will no doubt be carefully scrutinized by American experts familiar with local conditions.

is no light in his bedroom. Bombs have been dropped near his home and the windows broken since his return.

It is interesting to note that four of these five children have persistent symptoms in spite of the fact that they have returned home to relatively quiet areas.

Taking the remaining children who recovered, I have attempted to analyse the progressive assimilation of the incident in the different age groups. Children under the age of 1 cannot express their feelings by talking and are unable to move of their own accord to a place of safety. Of the 10 under 1 year of age 4 died—3 of infections unfortunately contracted within a fortnight of the raid. Conditions after the raid multiplied the chances of infection, and, though strict isolation was practised, it is perhaps significant that every child who developed infection died, and this 100% mortality suggests a lowered resistance in these young infants. Of the 6 survivors 4 never showed any signs of upset, one was a little upset at first, and the oldest, aged 10 months, still suffers from night terrors.

The next natural group appears to be from the age of 1 to 3. There were 15 of these, one of whom died of meningitis. Of these children 4 showed no sign of strain at any time; 2 still suffer from persistent symptoms. The most common reaction in this group was that to the noise of sirens, or to any noise: "She jumped at the least little noise"; "He knew what the sirens meant and was terribly anxious"; "She put her finger to her lips when the sirens went and seemed to listen, and cried." This reaction soon disappeared in spite of many subsequent alerts. These children are of an age to walk, and some of them ran for a safe person or place when the sirens went. The earliest example of this was seen at 1 year 11 months: "He came after me when the sirens went"; "He runs to anybody on hearing bangs"; said "Bombs, Mummy," or "Is it all clear?"; "He asked to go to shelter when the sirens went." Another reaction observed in this group was a failure to recognize the parents on return home. "She didn't know us when she came out" (1/11). "He didn't know me—he was a bit strange" (1/11).

It is not until the 3-year-olds are reached that any attempt is made by the child to describe the incident. At first the account is disjointed and fragmentary.

Joyce (3/0) said: "They took me away; they wouldn't let Daddy come."

David (3/5): "The black-out came down on me; the soldiers took me away in the car."

Elizabeth (4/1): "The ceiling came down on my bed. I had a ride with the soldiers in a car."

George (4/5) talked about the nurses running up and down the stairs and the bombs dropping.

Brian (7/5) told his parents how his hair was full of powdered glass, how the nurses showed the soldiers where to go, and how the soldiers carried him out.

In this group of children, aged 3 to 7 years (13 cases), there was a slightly earlier phase noted when the child attempted to reject or deny the experience.

Graham (2/5), though talking well when he went into hospital, found for some time say nothing but "No" when he came home.

Sylvia (3/0) never talked about the raid.

Janet (3/0) wouldn't say a word at first, and then talked to her dolls as I have described.

Patricia (6/5) never spoke of her own accord of the raid.

Gladys (8/0), who was choreic, never spoke of the raid. She was described by the ward sister as "too awfully normal," but for some time would not play with the other children or join in the ward games. She is quite happy and bright now.

But in the next group of children, aged 7 to 11 (8 cases), there was a tendency to accept the raid as an adventure.

Brian (7/5) treated the raid and subsequent bombings as a joke, but he was upset when evacuated to Cornwall. He had an unlucky billet with a very rough coarse-mouthed foster-father, and was eventually rescued by his father. On his return home he was shy, and cried when spoken to.

Robert (11/0) thought it was thrilling; he was very excitable and rather manic. He wrote a vivid description of his adventures to an aunt, who forwarded the letter to Mr. Churchill, and the Prime Minister's letter of acknowledgment is now a treasured family possession.

In the last group of children (11 to 12½), of whom there were 4 cases, there is an example of a sense of responsibility for the younger ones.

David (11/6) would not leave his ward until all the other children had been evacuated. He asked the nurses to allow him to help them in carrying children out. He paid for his self-control with enuresis after subsequent air raids, and his mother noticed that in severe raids in the following months the only sign of nervousness was a tendency to talk all the time he was in the shelter.

Another point of interest is the reaction of these children to subsequent incidents, when their homes or hospitals were again hit. Leaving out the youngest child, who had been born in an air raid, there were 8 of these.

Ruth (4/0), after the original raid, was evacuated from my hospital when it was severely damaged by a bomb, and a month after her return home she saw the house on the opposite side of the road blown sky-high in a daylight raid. Yet I found her putting her dolls to bed on the front door-step opposite the ruins, quite friendly and charming. She had a stable father, leader of a first-aid party.

Elizabeth (4/1), in a subsequent raid in another town, talked of her previous experience.

Patricia (7/0), five months after the first incident, was in a hospital which was damaged by a bomb, but was quite cool and showed no signs of upset.

Diana (9/1) was cool in a raid at home when her mother and two sisters broke down, and was bright and happy in a raid when another hospital to which she had been moved was hit.

Doreen (10/5) went "hysterical" in the shelter at home in the next raid and was shaken by her disgusted father, a naval petty officer. She was evacuated to Devonshire a month later, settled down happily, and is looking very well.

Robert (11/0), the enthusiastic letter-writer already referred to, was transferred to another hospital in a town which was bombed two months later. The windows were blown in. Two months afterwards, in yet another hospital, the windows were again blown in by a near miss. Beyond being rather excited, he was not upset.

Grace (12/10) two months after her return home found the house wrecked when the family emerged from their Anderson shelter. But she is sleeping well and is looking better than ever she did.

Bernard (12/0) told his father how the ceiling, plaster, and glass came down on his bed: he thought he would be buried alive. In a subsequent raid he heard bombs whistling down, and dived under the bed so quickly that he cut his head open and was the only casualty. But he sleeps well now and, though he is an epileptic, has had no recent fits.

Summary

Of the children exposed to a major air raid 61% showed signs of strain for a period of between three weeks and two months.

After seven months 11% of children still show persistent symptoms.

Persistent symptoms have not occurred in children under 1 year or over 5½ years of age.

The incident is assimilated in varying degrees according to the stage of development of the child's personality.

The earliest reaction is that to sirens and noise in general. In the walking child there is an attempt to run to safety. Later, in the talking child, there is an attempt to reject formulation of the experience, followed by an effort at describing or rehearsing

the incident, the description becoming more elaborate as the child is more mature. About the age of 7½ the tendency is for the child to accept the incident as an adventure. Finally, about 11½ a sense of responsibility for others appears.

The reaction to subsequent raids was on the whole remarkably slight. Out of 8 children who had severe later experiences only 2 showed pardonable anxiety, and they made rapid adjustment.

The most striking finding of this survey is the extraordinary toughness of the child, and his flexibility in adapting to potentially threatening situations.

I am indebted to my house-surgeon, Dr. Monica Hawkins, for tracing records while these children were in my hospital; and to Miss Pierson, the almoner of the Children's Hospital, and Miss Taylor of the Royal Hospital, Bristol, for help in tracing addresses.

THE NATION'S DENTAL SERVICES

PLANNING BY STUDENTS

A joint committee of dental students representing five London hospitals—Guy's, King's College, the London, the National Dental Hospital, and the Royal Dental Hospital—in co-operation with some dental schools in the Provinces, has prepared a memorandum¹ on the nation's dental services. It is a forthright document, especially in its analysis of dentistry as a career and its criticism of methods of teaching.

"Deplorable" Status of Dentists

The public status of the dental practitioner is declared to be deplorably low. The widespread ignorance of the nature of dental disease, and especially of its effect on systemic conditions, is described as appalling. Little more than £5,000 a year has been spent (by the Dental Board) on educating the ignorant public in the elementary principles of oral hygiene; some educational work is also done by the Central Council for Health Education, which the memorandum erroneously describes as a "department of the British Medical Association." The majority of the population have never been reached by dental propaganda, except by way of advertisements for proprietary tooth-pastes. Fear of the dentist's chair is still a factor to be reckoned with, and is considered by the students to be a serious reflection on dental technique. They believe that more research should be devoted to painless dentistry, but the responsibility lies very largely with the individual practitioner to cause his patient as little discomfort as possible while not impairing the efficiency of his work.

Dental attention at child welfare clinics impresses the students as inadequate, though varying from county to county. The school dental service is a valuable effort, but only about 65% of the children receive attention, and for these the facilities are too irregular to permit any degree of thoroughness. The fundamental fault in the school dental service is the lack of sound training for dental surgeons in child dentistry, including orthodontics. The gap between school-leaving age and the age of eligibility—19—for the additional benefits scheme under national health insurance is one of the greatest of the shortcomings, and the insurance scheme itself has many drawbacks. Incidentally the students praise the dental clinics which in London and elsewhere set out to meet the needs of the poorer sections of the community. These are often referred to as commercial practices, for although the charges are cut to a minimum they are run as extremely profitable concerns. "We have watched the work of some of these clinics and have been favourably impressed by the quality of the work they turn out." About seventy large firms employ part-time or whole-time dental surgeons for their workpeople.

Dentistry as a Career

Only a comparatively small proportion of the population can afford to pay the full fees of private practitioners, but it is in this field that the great majority of dental surgeons work. The

¹ Issued by the Planning Committee of Dental Students, Royal Dental Hospital of London, Leicester Square, W.C.2. (1s.)

Dentists Register, with between 14,000 and 15,000 dental surgeons and dentists, has remained almost stationary for the last fifteen years, and with the gradual dropping out of the "Dentists 1921" it is unlikely to show any marked increase in the near future. During the years from 1927 to 1937 the *Medical Register* showed an increase of 6,572, the *Dentists Register* an increase of only 204. In the United Kingdom there are four doctors to every dentist, but the *Register of Students*, 1938-9, shows the ratio of medical to dental students to be nearer six to one. Of those on the *Dentists Register* about 55% hold a diploma (L.D.S.); less than 2% hold the B.D.S., and less than 1% a higher qualification. The training is long and expensive. An initial outlay of £1,000 is necessary for education and subsistence, and from £500 to £2,000 for the purchase of a practice. The provision of more numerous and valuable scholarships and bursaries is urged.

In peacetime an average of only 24 women qualify annually, but school dentistry offers great scope for women, who also stand a better chance than men as candidates for posts of dental surgeons to maternity and child welfare centres.

Dental Education

Criticism of the methods of teaching is on the grounds of lack of modern apparatus, inadequate knowledge of modern methods on the part of the teachers, a tendency to ignore backward students, and insufficient supervision and aid from professional dental mechanics. Co-operation with manufacturers of dental goods, most of whom are willing to demonstrate their own techniques to students, is discouraged. A serious shortage of trained whole-time teachers is said to exist at all stages of professional training and at nearly all hospitals. Use is made as a supplementary provision of honorary visiting surgeons and demonstrators, but this is unsatisfactory for several reasons, one being that the student is often "taught two conflicting methods for the same operation on two consecutive days."

The examination system, while its advantage is conceded, has the drawback that the setting of a limited syllabus in certain subjects leaves to the teacher the responsibility of extending the syllabus; also that in marking examination results no account is taken of the student's hospital record.

It is also complained that the education of medical students in dental matters is neglected. The general practitioner of medicine is declared to have little or no knowledge of dental conditions and is rarely in a position to advise his patients to obtain dental treatment until some acute trouble arises. "Further, their lack of training in the administration of anaesthetics for dental operations renders them often almost a menace when called upon to perform this task." Again: "A medical house-surgeon is often expected to extract teeth with no previous experience of the operation whatsoever, and even no real knowledge of the anatomy of the parts concerned." It is considered that there are advantages in taking medical qualifications, however low, as well as dental qualifications. The dental surgeon can then speak to the medical man on equal terms.

Dentistry in Wartime

The work undertaken by the dental services with the Forces is mainly "conditioning"—that is, rendering a man dentally fit without impairing his masticatory powers. The tendency is to maintain Service personnel by depleting civilian practice, with the result that a position is arising in which there are not enough dentists to treat the civilian population or to maintain the standard of school dentistry. "Eighty per cent. of the younger members of the profession will have been absorbed into the Forces by the end of this year in order to change the neglected mouths of soldiers into examples of first-class conservative technique. But the school dental service, attempting to cater for the adults of to-morrow, has to pay as large a toll as any other branch of the profession to satisfy the demands of the War Office." It is considered that it would have been better to establish the wartime organization of the profession so as to provide only the most essential treatment for the Forces while doing everything possible to overcome the difficulties of treating the fluctuating evacuated populations and to ensure the best service for children and adolescents. In one West of England town where, before the war, one dentist working half a day a week

was able to cope with all demands, a bombed-out dental surgeon has now settled, and is seeing 200 patients a week.

Up to now the problem of calling up the "Dentist 1921" has not arisen, all such men being over military age. It is owing to the inclusion of these men that the average age of dentists is so high; 65% of those on the Register are aged between 45 and 65.

The memorandum urges that all these questions should be the subject of a conference to which a wide representation of the dental profession, of its ancillaries, of health services in general, of approved societies, and of Government Departments should be called.

Local News

SCOTLAND

Scottish Sanitary Congress

The sixty-sixth annual congress of the Royal Sanitary Association of Scotland was held recently in Glasgow under the presidency of Mr. Frank Preston, who in his opening address urged that plans should be prepared now to meet the transitional period from war to peace, and that planning should be of three types—national, regional, and local. In a paper on precautionary measures against infectious diseases Dr. Frank Main, M.O.H. for Perth, emphasized the need for a drastic overhaul of the procedure of exclusion from school for varying periods of all contacts of infectious disease. He said that many thousands of school attendances were lost every year by exclusion of contacts which could be saved without the slightest danger of an increase in the incidence of infectious diseases. Under the present rules a contact of mumps must stay away from school for twenty-one days, while a child with a severe cold might, and usually did, remain at school and infect the whole class. Colonel Sir Alexander Russell, I.M.S. (ret.), of the Department of Health for Scotland, stressed the importance of immunization against diphtheria, pointing out that pre-school children were by far the most susceptible to this infection. Out of an estimated child population in Scotland of 1,124,500 only some 600,000, or about 53%, had so far been immunized against diphtheria. It seemed wrong that, in the name of liberty of the individual, parents could veto the protection of their children against disease and untimely death.

Neurosurgical Unit for Glasgow and the West

Meetings have recently taken place between representatives of the Glasgow Corporation hospitals and of voluntary hospitals to discuss a plan for establishing a single unit for neurosurgical treatment of patients from Glasgow and the West of Scotland. Agreement upon general principles has been reached, and the Department of Health for Scotland has undertaken to place at the disposal of the area a number of beds and facilities for operative surgery at its hospital at Kilmarnock, to which both civilian and casualty patients would be admitted. The Health Committee of the Glasgow Corporation has adopted a resolution recommending approval of this plan as a temporary arrangement during wartime.

The September issue of *Industrial Welfare and Personnel Management*, the journal of the Industrial Welfare Society (14, Hobart Place, S.W.1, price 1s.), includes articles on "Lighting for the Older Worker," by E. B. Sawyer, manager of the Lighting Service Bureau, and on "Foot Wear and Tear," by W. Sayle Creer, M.Ch.Orth., F.R.C.S., who suggests that firms should establish foot clinics needing only very simple essential equipment and a chiropodist (full- or part-time, depending on the number of workers). "In the minds of medical men who have experience of the value of the chiropodist there is no doubt at all that the establishment of foot clinics in industry is something not to be discussed as a possibility or as a luxury but as a necessity and one which quickly repays the money spent on it."

Correspondence

Voluntary Hospitals

SIR.—Sir Frederick Menzies asks: "What are the particular virtues of the voluntary hospital system which are conspicuous by their absence in the municipal hospital system?" Without attempting a comprehensive answer to this question, I would like to mention a few of these virtues.

1. The control of the work of the hospital by a medical committee, consisting of all the members of the senior staff, with a chairman elected by them and re-elected and changed at frequent intervals, no medical superintendent taking full final responsibility.
2. Recommendation for election to the medical staff, of all grades, by the medical committee, of the future colleagues.
3. Part-time visiting senior staff, individually having sole and final personal responsibility for each patient under his care. These members of the staff may hold part-time appointments at another hospital of a different type, do non-institutional work, and see patients in their own homes, thus having a broad professional experience.
4. Apprenticeship system of junior resident staff, each personally responsible to, and each individually trained by, a member of the senior visiting staff.
5. Admission open to all, and not restricted to local government boundaries.

These points will not, I think, be disputed by many of those who believe that the voluntary hospital system has something of real worth to contribute to the health services of the future. I have purposely not enlarged on them. But I must, even at the risk of Sir Frederick Menzies calling this a "Niagara-like cataract of words which are entirely meaningless," mention a much more controversial point. In my view the voluntary hospital system, largely owing to the above features and to the absence of cramping central control, provides great scope for the development and expression of individual initiative and personal responsibility, both so essential to good and satisfying work in clinical medicine.—I am, etc.,

London, Sept. 15.

B. A. BUTTERWORTH.

SIR.—Sir Frederick Menzies's pertinent question (September 6, p. 353), "What are the particular virtues of the voluntary hospitals which are conspicuous by their absence in the municipal hospital system?" is apposite and of fundamental importance if the new hospital (and medical) system which is in the process of forging is to be an improvement. In evaluating the voluntary hospitals the three types should be noted—the teaching, the non-teaching staffed by consultants with over 100 beds, and the cottage hospital; the advantages are not entirely enjoyed by the last. The object of this letter is not to "make a case" for the voluntary hospital, but to try and articulate that happiness, that freedom and apparent superiority of the voluntary hospital, so that the pattern is everywhere available for patients.

The particular virtues of the voluntary hospital are:

1. The primary importance and independence of the clinician. The clinician accepts full responsibility for every patient in his beds and inspires the full loyalty of the staff—medical, nursing, and lay—for his patients. The system of "firms" with their rivalries develops initiative; the periodic visits assist discipline.
2. The staffs and departments of the voluntary hospitals are "open" for all to see. Students, general practitioners, and postgraduates are welcomed and encouraged to discuss and to criticize the clinical work.
3. Many voluntary hospitals have that precious possession tradition, in some cases of many centuries of service. The value of tradition is difficult to define but is easy to feel and recognize. Tradition, however, is not vital, for I have seen new voluntary hospitals staffed by consultants capture the "spirit" in a decade.
4. The voluntary system still provides the leaders, the thinkers, the writers, and the teachers in medicine and surgery.
5. The system of private consulting practice associated with the voluntary hospitals exerts an instructive and co-ordinating influence between the medical services and doctors of the district.

Residents, mostly prospective general practitioners, receive valuable tuition from a chief so engaged.

6. The "open" out-patient system enables doctors to select the man (not the department) possibly 100 miles away who will meet the needs of their patients.

7. Then the monthly medical committees and subcommittees—for example, the nursing and instruments—where hospital management is "thrashed out" in the light of the needs of the patient, of the district, and of experience garnered from other hospitals where the staff also serve, are invaluable. The practice whereby new developments and apparatus must be justified by the member of the staff to the satisfaction of his colleagues is excellent for practicability and economy. Although large institutions (as in London) may be able to buy cheaply, it is expensive to buy unsuitably.

8. In the voluntary hospitals the number of residents and visiting staff per bed is probably much higher than in the municipal hospitals. The voluntary hospitals are always working to capacity, at high pressure with usually efficient clinical service and a quick turnover.

9. They are generally short of money, and careful economic service is general.

From my own experience of municipal hospital service I recall that:

1. In municipal hospitals the first loyalty of the staff—medical, nursing, and lay—is to the Organization, which may, and indeed does, override the clinicians and may come between the clinician and patients.

2. The entrance gates of a municipal hospital are guarded, access is not easy, medical or surgical pilgrims need authority before they are allowed to enter. Patients, too, demand something more personal than a hospital superintendent or county hall. In supporting voluntary hospitals patients enjoy some pride of ownership and responsibility.

3. The municipal hospitals with clinicians holding the highest qualifications have been vigorous for some fifteen to twenty years. It may be apposite to check the original work and writing which has been forthcoming from this wealth of clinical material. How many of the staff are active members of the various medical societies? Does the organization actively encourage membership of learned societies and attendance at professional meetings throughout the country, or is this "mixing" with fellow clinicians passively resisted?

The voluntary hospital is a free, open institution made by its honorary medical staff and large-hearted laymen. The municipal hospital is usually a closed efficient organization; the first savours of a democracy, the latter of totalitarianism; both can be good or bad. The problem is to fuse the independent yet responsible visiting staff of the voluntary hospital with their clinical freedom with the fine organization of the municipal hospital.—I am, etc.,

London, W.1, Sept. 20.

HAROLD DODD.

The Mental Defective in the Army

SIR,—The further letters elicited by Dr. Esher's article (August 9, p. 187) prompt me to return to the subject with your permission. I ventured in my letter in your issue of August 23 (p. 280) to suggest that Dr. Esher's proposed mental age standards were too high, and since then others have written to the same effect in greater detail.

The article referred to virtually asked the question: "Can the mentally defective man play any part in the modern armed Forces?" Gross degrees of deficiency are not, of course, being considered. Experience as a former medical officer in one of the Forces and in the colony for mentally defective men of which I have charge leads me to the belief that a fair proportion of feeble-minded men, otherwise healthy, can be satisfactorily utilized in certain units of the Forces, and that too high a standard of intelligence estimated by "test" at recruitment will lose the useful services of many.

The question of stability has been suggested very properly as one of the major criteria. Out of my present population of 420 defective men, some 250 are feeble-minded with mental ages of over 6½. During a longish period of frequent nocturnal air attack in the immediate area it was repeatedly observed by members of our staff that these men showed few signs of fear, pre-

served good discipline voluntarily, and rapidly became philosophical to the most exasperating discomforts. There was never any panic among them, even when a shelter containing thirty had its entrance ramp demolished by a direct hit by a high-explosive bomb, fortunately without casualties. This may mean only lack of sensitiveness, but the result is the same. I do not, of course, mean to suggest that the mental age of 6½ is a suitable standard.

Dr. Herd (September 20, p. 422) warns us rightly that too much reliance should not be placed on "mental age" assessed by standardized tests. It is difficult to see in what other way a rapidly operating medical recruitment board can gauge mental capacity. If these tests must be used, and it seems they must, then let the minimal assessment, at least on enlistment, not be too high, for that would be as wasteful of personnel as too low a minimal assessment would prove to be of training effort once in the Forces.

Where the mentally defective soldier shows moral delinquency resulting in anti-social conduct, repeated acquisition of or concealment of venereal or dirt-borne diseases, he has obviously become a nidus of indiscipline and a source of inefficiency. It is largely such defectives who should be notified and handed over at once to the civil authorities, but I gather the state of our civil laws does not allow such action yet, so the Service concerned can only discharge him as "Services no longer required."

As regards the "weeding-out" by Army psychiatrists of these defectives who are making unsatisfactory soldiers, there is one small possibility, mention of which I trust will not be offensive. Many of the psychiatrists are practitioners who until recently had only association with aspects of life quite different from soldiering. They may sometimes unconsciously allow their decisions to be led by the opinions of the men's officers and N.C.O.s, whose object may be in some cases a short cut to a "smart unit."—I am, etc.,

Brenty Colony, Bristol, Sept. 20.

JAMES JOHNSTON MASON.

Depressive States in the Soldier

SIR,—I should be grateful if you would allow me to answer a few points raised after the publication of my article, "Depressive States in the Soldier" (July 26, p. 109).

I am sorry if I have attributed to Dr. C. H. Rogerson views which are not his. As he suggests desirable (August 9, p. 209), I endeavoured to curtail the neurosis-versus-psychosis argument as far as seemed possible, and I appear to have done this to such an extent as to have made false implications of his views—for which I must sincerely apologize to him.

Dr. Carver feels "bouts of narcotic substances" undesirable in shirking neurotics (as well as in alcoholics), but, as he will see from the table I showed, only very few of those who had prolonged narcosis could be so regarded: the latter treatment was reserved for patients with acute anxiety or making unsatisfactory progress.

I must thank Dr. Henry Yellowlees (August 16, p. 243) for his charitable and perfectly correct assumption that a slip of the pen was responsible for the misquotation of his views on insight; he was also correct in his assumption that the insight which I was venturing to assess was that of the patient rather than that of the physician.—I am, etc.,

Sept. 23.

R. F. TRINGOLD

Selection for the Army

SIR,—I was interested in your leading article on selection for the Army (September 20, p. 410), in which you reviewed the latest report of the Select Committee on National Expenditure. This report is "chiefly critical of the allocation of man-power once it has passed into the Service—not the occasional acceptance by the Army of medically unfit men, but the assignment of men to military occupations for which they are mentally ill adapted." With regard to the selection of officers, the committee holds that "the qualities essential to an officer cannot be ascertained solely by testing."

Since this report raises a really urgent and serious problem I venture to direct your attention to a psychological method of selection and allocation which appears to be wider in scope than intelligence tests—the analysis of handwriting, known as graphology. It is well known that the German War Office

have made use of this method for purposes of selection and allocation for the last ten or fifteen years, and particularly with regard to selection of officers and men with specially responsible tasks this method seems to have worked out satisfactorily. According to G. Kiergie, Hitler's air-pilot was selected with the help of an examination of handwriting (*News Letter*, vol. 4, No. 53, p. 641). In this country some child guidance clinics and institutes such as the Institute for the Scientific Treatment of Delinquency, as well as important business firms, have availed themselves of this method and have expressed their satisfaction.

I myself have had good results from graphological reports on patients of mine, not only with regard to their psychological problems but also as regards their vocational suitability. I have come to use graphological reports much in the same way as a physician will use laboratory or x-ray reports, for it is often possible for a graphologist to see at once into an aspect of the personality which can otherwise only be grasped after long investigation. I know that other psychotherapists have had similar experiences.

H. J. Jacoby reports that the graphological method was tested on an experimental-statistical basis, yielding a high degree of reliability—between 85% and 93% (*Analysis of Handwriting*, 1939, pp. 26-7 and 40), while R. A. S. Paget suggests that it may be useful to carry out similar control tests of this method in this country (*Nature*, April 27, 1940). Ernest Jones maintains that "graphology is now in a position to supply the data in an accessible form" (*Internat. J. Psycho-analysis*, vol. 21, October, 1940 part 4). It is my opinion that the task of interviewing officers could be shortened and lightened by the analysis of handwriting, which can ascertain essential personality qualities that cannot be discovered by interview and intelligence tests, and that this method, if applied in a reasonable and critical way, may fill a serious gap in the psychological means of selection and allocation in the Army at present at our disposal. The Ministries concerned should have no difficulty in obtaining the services of qualified advisers.—I am, etc.,

Nottingham, Sept. 22.

MICHAEL FORDHAM, M.R.C.P.

Wholemeal Bread

SIR.—A general practitioner in earnest mood who bursts into print expects a certain amount of good-natured chaff from his friends, who perhaps read the first and last paragraphs of his letter. He also faces the possibility of kindly comment or caustic criticism from the experts. But rarely, I conceive, does he evoke such extraordinary criticisms as I received in a letter from Mr. J. C. Mottram (August 16, p. 244) in reply to my letter on wholemeal bread (July 12, p. 64).

The winning of this war may depend on the health of our nation. From a nutritional point of view wholemeal is of great importance to the community. It is sad, therefore, to hear it derided on account of two fallacious arguments, and more than disturbing to find it being replaced by so-called national wheatmeal, whose specification is such that it can comprise a variety of meals chameleonic in colour, kaleidoscopic in appearance, rich or poor in vitamins as the miller decides in his "gentleman's agreement" with the Government. It is illuminating by way of comparison to read the strict, detailed, definite specifications for animal feeding stuffs under the Feeding Stuffs Act.

The two fallacious arguments are: (1) that the roughage of wholemeal is undesirable in wartime; and (2) that wholemeal has very poor keeping qualities. I advocated wholemeal as the staple bread because of its splendid nutritional value, especially for its iron and vitamin content. I pointed out that the M.R.C. preferred 85% extraction flour because "it is undesirable to increase the roughage in wartime diets." I suggested that this was a matter of opinion, for I could find only one reference to experimental work on the effect of roughage on the intestine, and this was not derogatory. Mr. Mottram gives six references "which may be added to the single one mentioned." Is Mr. Mottram pulling my leg? I have looked up the first four (two of which are incorrectly given) and was extremely surprised to find that none of them had anything to do with the subject of roughage and the alimentary canal! I confess I was so disappointed that I did not look up the last two. But, after all, a joke is a joke!

I pointed out that till recent years wholemeal was the only wheatmeal available and was eaten in double the quantity it is to-day. Mr. Mottram has it from "personal knowledge that

germ meals consisting of a mixture of white flour and germ have been available to the public for over fifty years." The fault is mine; I apologize for the indeterminate "recent." As the hymn says: "A thousand ages in Thy sight are like an evening gone." My recent years started just before the fifty years of Mr. Mottram, which makes my statement no less true.

The M.R.C. objected to wholemeal because it could only be kept under reasonable conditions of storage for "four to six weeks or longer." I described an experiment wherein samples of wholemeal were kept in a bakery for six months without signs of deterioration. Mr. Mottram says "this is not a fair test, as it would not be practicable under ordinary manufacturing conditions to store flour at such temperatures in the summer." Mr. Mottram disappoints me. If a bakery in June, 1941, was not hot enough for experimental purposes, one might have to wait a long time for a hotter month. But his remarks suggest that he has some evidence on the keeping qualities of wholemeal and germ meal. I cannot find a single reference—not even one experiment on the susceptibility of wholemeal to the mysterious disease known as "rope"—to which he refers. If he has some evidence will he please bring it forward?

Here, then, is the position to-day. National wheatmeal is official. It will vary in value from loaf to loaf. No check is made on its iron or vitamin content. We "kid" ourselves that we are feeding the population scientifically.—I am, etc.,

Leeds, Sept. 24.

R. A. MURRAY SCOTT.

Communal Feeding in Schools

SIR.—There are good reasons for making attendance at communal feeding centres compulsory. Their establishment cannot be justified by attacking any one class of the community; nor can they be justified by imputing such a degree of ignorance that appals and such a lack of intelligence that creates despair of ever training mothers of the working class in the right ways of diet. I also have been appalled by the ignorance manifested in food values. It is not the ignorance of the mothers of the working class that appals me; it is the ignorance, or rather the apathy and indifference, of our own profession to the modern facts of nutrition. For example, it seems, so far as I have been able to discover, that no systematic inquiry is made into the habitual dietetic habits of a patient either by general practitioners or by physicians at hospital out-patients. Again, is there any member of the medical boards established under the Military Service Act whose duty it is to study the dietetic habits of the new recruit?

Further, one of the main factors leading to diet deficiency is the use of white bread. In 1940 it was stated in Parliament that 95% of flour milled was white; 95% of all families, including professional and working class, therefore, consumed an article of food deficient in calcium, iron, and vitamins. Ignorance of food values is not peculiar to any one class.

There is a certain type of child for whom compulsory attendance is necessary. It is not a child from a family of the working class where there is lack of food and lack of knowledge of food values: there are other ways of dealing with these situations; it is the child who has developed faulty feeding habits. In my experience the child who is more likely to fall ill is the one who refuses to eat the food that the parent provides. The ignorance shown by the parent is not so much of food values as of how to persuade or to train the child to eat the food that the parent knows is good. This is the faddy child, or the one who does not like meat or fat, green vegetables or milk. Such children should be sought for by the medical or nursing staff of the public health services. Faddiness is apt to develop after acute catarrhal illnesses of the respiratory tract. After a preliminary period of residence at a convalescent home these children should be sent to a communal feeding centre. The purpose of such treatment is two-fold: first, to change the faulty feeding habits, and, secondly, to establish sound habits of feeding. Compulsory attendance should be maintained for a definite period of six months or longer, according to the home situation. The failure of the parent to establish right feeding habits should be thoroughly investigated. After the cessation of the period of compulsory attendance the child should be supervised, the home visited, and the co-operation of the parent enlisted to maintain the healthy habit of feeding.—I am, etc.,

P. A. GALPIN,
Tuberculosis Officer.

London, E.13, Sept. 15.

Cysticercosis Epilepsy.

SIR,—In reply to Dr. C. W. Ewing's article on cysticercosis epilepsy (August 23, p. 263), in which information is requested as to the presence of cysts in the cerebrum in the case reported by me, I have to state that radiographic films of the skull proved inconclusive in this case. There was an opaque object situated in the left frontal region, but as the degree of opacity was less than in the other cysts it was considered advisable to carry out radiographic examinations on the case at yearly intervals in order to assess the degree of calcification rather than to make a definite diagnosis at the time. The cerebral findings were therefore omitted until such time as more definite evidence of intracerebral calcification of the cysts became available.—I am, etc.,

Glasgow, Sept. 18.

WILLIAM BLYTH.

Scabies: Questionable Evidence of Cure

SIR,—Medical journals continue to report treatments for scabies. Each writer finds his or her method efficient; cases reported on are often few, and control by dermatologist or entomologist is almost invariably lacking. Successes are claimed on questionable evidence. How many readers (or contributors!) are aware that scabies may for weeks be undetected and cause no local discomfort? Absence of obvious lesion and irritation is no proof of cure. Presence thereof provides no evidence of persisting infestation.

Kenneth Mellanby has already shown that we may be blindly accepting prejudiced concepts. His work to be published later may still further disillusion enthusiasts who claim discovery of a panacea. Personal investigation and conversation with Mellanby's willing volunteers might enlighten contributors. Those called upon to treat scabies should accept reports in which test of cure is dependent on the absence of living acari. Superficial inspection and patients' comment recorded a fortnight after treatment should under no circumstances be regarded as criteria of cure.—I am, etc.,

P. B. MUMFORD, M.D., F.R.C.P.

Familial Neurofibromatosis

SIR,—Dr. A. Garland's memorandum on the hereditary nature of Von Recklinghausen's disease (August 26, p. 120) gets further support from three cases that have come under my observation. The father, a man of small stature who died comparatively young, had patches of brown pigmentation on the body, with masses of pedunculated and sessile tumours under the chin, on both arms, neck, chest, and back. His sister, a diminutive woman with marked kyphosis and scoliosis, has similar pigmentation and the same distribution of tumours. His two daughters have the neurofibromatosis on the arms, neck, chest, and back; but so far pigmentation has not developed. His father, who was small of stature and of a low-grade mentality, was a typical case of neurofibromatosis.—I am, etc.,

Wellington, Somerset, Sept. 20.

S. McCLEMENTS.

Treatment of Impetigo

SIR,—The letter from Dr. G. A. Grant Peterkin (September 20, p. 422) might well have been the last word in this correspondence, for 2% aqueous solution of gentian violet is a simple, effective, and economical treatment for impetigo, and the Edinburgh school deserves credit for popularizing it in British dermatological clinics. Ointments are less effective, and examples of impetigo, refractory or spreading under ointment, are common in large skin clinics, and many cases of sycosis barbae appear to be the result of ointment therapy. These unfavourable results might be expected, for a film of grease retains exudates and sweat, which encourage the growth of organisms and irritate the follicles. Nature's defence against skin infection is the dry, intact stratum corneum, and our treatment should be designed to maintain it.

The common types of impetigo are scaly, scabbed, bullous, circinate, and ulcerative, and treatment has to be adjusted accordingly. If healed lesions are present it indicates that the patient can cope with the infection without the aid of antiseptics, and simple cleansing with carbolic soap followed by the application of calamine lotion or a dusting powder to dry the active lesions will usually terminate the infection in three days. Scabs and crusts should be removed, and this is facilitated by the use of

hot compresses of 1% sod. bicarb. or 1% sod. sulphate, and then a lotion is applied to the clean red moist surface. Outpatients with exposed lesions prefer a less conspicuous colour than violet, and acriflavine 1/1,000 plus 4% tannic acid to diminish exudation when necessary is a good application, but lot. calamin. plus 2% phenol or the lotion of zinc and copper sulphate are just as useful, always providing that no idiosyncrasy towards them exists.

Under such treatment most cases resolve in five to ten days, but occasionally a deeper erythema around a lesion denotes a more virulent infection, and then prosectasine, 1 gramme t.i.d. for a week, and sulphanilamide powder to the lesions often cause dramatic improvement. Sulphanilamide is unnecessary and has no demonstrable effect upon the average case of impetigo. Ointments have a limited use in preventing the formation of hard crusts in the scalp over-night, but even for the scaly variety of impetigo a cream or paste is preferable to an ointment, and their use instead of the latter means a saving of 50% of the fatty base. No mention has been made of mercury, because, although of value, it is more essential to the national economy in war industries.—I am, etc.,

London, W.1, Sept. 21.

R. T. BRAIN.

Surgical Statistics for the General Surgeon

SIR,—I consider that Mr. J. C. Goligher, in his article on the operability of carcinoma of the rectum (September 20, p. 393), has presented statistics of the utmost value to the general surgeon, who also meets such cases constantly day by day. I have read his article again and again, and consider it to be just such a classical statistical record for our guidance as was that of Winsbury-White many years ago in the *British Journal of Surgery* on findings on prostatic cases at St. Peter's Hospital. Though many general surgeons have special leanings to certain branches, in these days we have to have the up-to-date figures of our colleagues for specialties which we also have to deal with, and they should be encouraged to publish such articles as the above quoted.—I am, etc.,

Oxford, Sept. 23.

HUGH WHITELOCKE.

Puerperal Tetanus

SIR,—We are grateful to Prof. Fletcher Shaw (September 20, p. 418) and to Mr. Owen-Jones (September 13, p. 388) for drawing our attention to the Tetanus Committee's report in the *Journal of Obstetrics and Gynaecology of the British Empire* for June, 1941, with reference to the anaerobic infection of vulval pads and infection of cotton-wools and cellular tissues after sterilization in manufacture, and on the difficulty of eliminating spore-bearing organisms unless absolutely rigid technique of sterilization is followed. But we must point out that our article on puerperal tetanus was submitted before publication of this report. In our article we had referred to foreign journals in view of the fact that we could obtain no reference to recorded cases occurring in the British Isles.

After perusal of the committee's report we find that S. Merriam, in 1838, reported one death from puerperal tetanus in 10,190 confinements, and J. Y. Simpson, in 1854, wrote an article on tetanus following abortion and parturition, and commented on the association of plugging the vagina in cases of abortion and the onset of tetanus.

The committee was not able to obtain recent statistics in relation to non-fatal cases, and it describes figures of fatal cases from the reports of the Registrar-General and from representative institutions with large maternity departments. The Registrar-General's figures showed that a century ago there were only two fatal cases in the year 1840, an incidence of 1 in 250,000. For the years 1927 to 1937 there were 10 cases, giving an incidence of 1 in 700,000 deliveries. Figures from the institutions recorded only one fatal case of tetanus.

The committee reported that in spite of the fact that the risk of tetanus may be very remote it was important to investigate the possible part played by dressings as a source of infection, and it felt that after investigations which confirm that cotton-wools and cellulose dressings are generally heavily infected with spore-bearing anaerobic bacteria, among them virulent strains of tetanus bacilli, there is nothing improbable that such dressings are a potential source of surgical and puerperal tetanus. It admitted that there are many other possible sources of infection with the *Bacillus tetani* in the puerperium, and, therefore,

it is not possible to be certain of the part played by dressings in the aetiology of clinical tetanus.

Though the matter is not yet quite clear as to whether infection of the vulva arises from infected pads or from the rectum, there still remains the unexplained query why the condition is so rare. We would point out that we have been unable to trace in the British Isles any case of recovery from puerperal tetanus—apart from that we recently published in your *Journal*.—We are, etc.,

BRUCE MACLEAN.
P. CHALLEN.

Newcastle, Staffordshire, Sept. 25.

* The subject of this letter was discussed in an annotation in last week's *Journal* (p. 445).—Ed., *B.M.J.*

Epidural Novocain Injection in Cervical Cancer

SIR,—I wonder whether any reader could explain the following, which I find rather puzzling. Cases of carcinoma of the cervix uteri with pelvic and perineal pain are relieved by epidural injection of novocain followed by saline (up to 200 c.cm.), and the relief may last for months. The effect can hardly be psychological, but I cannot think of a rational explanation of the relief of the pain, which is presumably due to pressure and strangulation of the nerves in the pelvis. There is no evidence of anaesthesia of the perineum following the injection, which rules out a forcible rupture of nerve fibres.—I am, etc.,

Sheffield, Sept. 22.

J. WALTER, D.M.R.E.

Obituary

ROBERT THIN, LL.D., M.B., C.M.

Past-President, Royal College of Physicians of Edinburgh

The death has occurred at the age of 80 of Dr. Robert Thin, a Fellow and former President of the Royal College of Physicians of Edinburgh; he had been a member of the British Medical Association for fifty-two years, held high local office in the Association, and attended many of the Annual Meetings.

The son of James Thin and Catherine Traquair, he went to the Royal High School, Edinburgh, and thence to the University, where he first took an Arts course and graduated M.A., and proceeded to the M.B. and C.M. degrees in 1887. After serving as resident surgeon and resident physician at the Royal Infirmary, and as resident physician at the Royal Hospital for Sick Children, he did postgraduate work in Vienna and Prague. On his return to Edinburgh in 1890 he set up in general practice and held a medical appointment at the Forth Bridge Works. He obtained the M.R.C.P.Ed. in 1892 and was elected to the Fellowship in the following year. He served the College as Honorary Librarian from 1923 to 1931, was Vice-President in 1928-30, and for a general practitioner had the unusual distinction of holding office as President of the College in 1931-3. On vacating the presidential chair he received from the University of Edinburgh the honorary degree of LL.D.

Dr. Thin joined the British Medical Association in 1890; he was chairman of the Edinburgh and Leith Division in 1922 and acted as its representative at five Annual Meetings of the Association, the last one being the Centenary in London. He was elected President of the Edinburgh Branch in 1924. He contributed articles to medical journals, mostly on the history of medicine; his writings included an interesting account of the old Royal Infirmary and earlier hospitals, and under the title "College Portraits" a group of attractive biographical sketches of the medical worthies of Edinburgh in former times.

In the daily round of practice Dr. Thin gave of his best to all who sought his help, and the skill and sympathy he bestowed upon them won him the love and gratitude of his patients and their friends. He had no doubt about the high place of the family physician in the framework of medicine, and his long life of service bore testimony to this conviction.

J. LOUGHEED BASKIN, M.D.

Dr. Joseph Lougheed Baskin of Worminghall, Bucks, who died at Oxford on August 30 at the age of 71, was a distinguished physician and neurologist.

Born at Enniskillen, son of the Rev. Charles Baskin of Belfast, he was educated at Armagh, and took the Scottish triple qualification in 1897 after studying medicine in London, Cork, and Edinburgh. In 1911 he obtained the Brussels M.D. His life-work was devoted to psychiatry, which he practised in many different institutions. He served as medical officer to the Belfast Mental Hospital, the Royal Albert Hospital, Devonport, and the Devon County Mental Hospital, Axminster. In more recent times he was special neurologist for the Ministry of Pensions at Maudsley, and did a spell of post-war duty at Ashurst, Littlemore. For many years he was superintendent at Fisherton House, Salisbury, when it was the largest private mental institution in the country. Dr. Baskin published a number of papers in medical journals, including articles on katatonia and on the influence of gardening as a form of treatment. He was a member of many learned societies, all connected with his branch of medicine, and his work was always marked by its originality and analytical character. He had long been a keen member of the British Medical Association, and frequently attended the Annual Meetings, where he took special pleasure in promoting the social activities of the Irish members. He served as secretary of the Section of Neurology and Psychological Medicine at the Brighton Meeting in 1913, and was for some time secretary of the Irish Medical Schools and Graduates Association.

In his time, writes a colleague, Dr. Baskin was well known in many directions outside his profession. He was a minor poet of some distinction, and his work, mostly of the pastoral lyric or sonnet type, was favourably known to many, including Dr. Robert Bridges. His interest in sport was diverse, but he excelled in aquatics, and he had many awards as an expert swimmer in the South of England. Dog breeding and exhibiting was a hobby, and while in Salisbury he was admitted to be the leading breeder of Pomeranians. He was an instinctive naturalist, and his wide knowledge of plant, tree, and bird life was a never-failing mine of information for those who sought his advice. His later years were given up to intensive teaching of first-aid and ambulance work in many of the villages surrounding his home. He served with distinction in the last war, where he saw service with a battalion of the London Fusiliers and later with a heavy artillery brigade. He was severely wounded at Messines and recommended for the Military Cross. His was a very full life, and he served well his generation and his country.

B. R. ARCHER TAYLOR, M.R.C.S.

We regret to announce the death, on the eve of his eighty-sixth birthday, of Dr. Benjamin Robert Archer Taylor at his home in Meckering, Western Australia. He had belonged to the B.M.A. for fifty-eight years and was the oldest member of the Western Australian Branch.

Dr. Archer Taylor was born on June 29, 1855, at Tottenham, Middlesex, and on leaving school was entered at Lloyds. He was still there when Ferdinand de Lesseps visited England not long after the opening of the Suez Canal: the visit left a deep impression on his mind, and he often related how the company sprang as one man to its feet cheering wildly. Finding the work at Lloyds too slow for his vigorous spirit, he resigned his position and began the study of medicine as a student at Guy's Hospital. The four senior surgeons at Guy's in his day were Cooper-Foster, Thomas Bryant, Arthur Durham, and Henry Howse. He acted as dresser to Cooper-Foster, and related that on one occasion while he was at work Arthur Durham came in and stopped at the bed of the patient whom he was examining. Durham entered into conversation with Cooper-Foster and a discussion arose regarding Listerism, which had then come into vogue: Durham said with sarcastic humour, "These Listerites will soon be opening the peritoneum." Of the four senior surgeons, Howse was the only one who had adopted the teachings of Lister at that time: he was the junior of the four. Lister had been appointed Professor of Clinical Surgery at King's College, London, just a year before this.

The Services

NAVAL AWARD AND COMMENDATION

The D.S.C. has been awarded to Temporary Surgeon Lieut. Alexander Gibson Reid, R.N.V.R., for bravery and devotion to duty during an enemy air attack in which H.M.S. *Mashona* was sunk; and Surgeon Lieut. Joseph Patterson, R.N.V.R., has been commended for bravery during an air raid on Plymouth.

AIR FORCE AWARDS AND MENTIONS IN DISPATCHES
The O.B.E. (Military Division) has been awarded to Acting Wing Commander James Proctor Huins, A.A.F., and to Acting Squadron Leader Benjamin Charles Curwood, R.A.F., in recognition of distinguished services rendered in operational commands of the Royal Air Force during the period October 1, 1940, to March 31, 1941.

Acting Group Captain Percival Maurice Keane, R.A.F., Acting Squadron Leader Thomas Arthur Hunt, R.A.F., and Squadron Leader Malcolm Langley Maley, R.A.F.V.R., have been mentioned in dispatches by Air Officers Commanding-in-Chief.

CASUALTIES IN THE MEDICAL SERVICES

ROYAL NAVY

Prisoner of War

Surgeon Lieut. Patrick Christopher Steptoe, R.N.V.R.

Medical News

A meeting of the Section of Orthopaedics of the Royal Society of Medicine will be held at Horton Hospital, Epsom, on Saturday, October 11, at 2 p.m., when short papers on "The Problem of the Foot in Service Cases," "Psychological Reactions to Injury," "Conditions of the Back simulating Visceral Disease," "Spinal Cases of Interest," and "Some Points in the Diagnosis of Osteochondritis of the Knee" will be read. Clinical cases and x-rays of interest and special cases will be shown, and there will be a demonstration of physical treatment.

At the annual meeting of the Hospital Saturday Fund, presided over by the Lord Mayor of London at the Mansion House, Sir Walter Womersley, M.P., Minister of Pensions, said that the restoration of disabled men to employment had been the subject of frequent conferences between the Ministry of Pensions and the Ministry of Labour and National Service. Everything is being done, he said, to ensure that while the disabled man receives treatment in hospital he is also considered in relation to his employability, so that there may be no delay in putting him into direct contact with the training schemes that are being developed by the Ministry of Labour.

On Saturday, September 27, the Chartered Society of Massage and Medical Gymnastics held a half-day congress in the Cowdray Hall of the Royal College of Nursing, Cavendish Square, W. The Founders' Lecture, at which Lord Horder took the chair, was given by Prof. F. Wood Jones, F.R.S., F.R.C.S., on "The Muscles of the Body Cavity."

Sir Bernard Docker, as chairman of the British Hospitals Association, has approached the Ministry of Health with regard to the growing difficulty experienced by all hospitals in getting and keeping domestic staffs, a matter which has been publicly ventilated in the *Times* by a letter from Dame Agnes Hunt, honorary superintendent of the Shropshire Orthopaedic Hospital.

The September issue of the *Glasgow Medical Journal* (Alex. Macdougall, 104, West George Street, 3s.) opens with an article on the effort syndrome by Lieut.-Colonel J. Gibson Graham and Captain J. D. Olav Kerr, and includes an Educational Supplement giving full particulars of the curriculum at the Glasgow Medical School.

An epidemic of infantile paralysis, the largest in the history of the province, has recently broken out in Manitoba. In the latter part of August there were more than a hundred cases. Most of the attacks are slight and there have been only a few deaths so far.

The draft Defence Regulation referred to in this column on September 13 (p. 390) came into operation on October 2, from which date no paraffin emulsion may be manufactured containing more than 25% volume in volume of liquid paraffin.

Archer Taylor qualified L.S.A. in 1880 and M.R.C.S. in 1881. Not long afterwards he bought a practice at Kendal, Westmorland, where he remained for over twenty years: he was on the committee of the Westmorland County Hospital and was also a magistrate for the Borough of Kendal. An acute attack of rheumatic fever caused him to turn his thoughts to a warmer and drier climate, and he applied for a practice at Broome, Western Australia: his application, however, came too late, but his eyes being turned towards Australia, it was only a matter of time when an opportunity presented itself. Sir Gerald Strickland of Sizar Castle, Kendal, having been appointed Governor of Tasmania about that time—he was later Governor of Western Australia—reports reached Dr. Archer Taylor concerning the favourable climate there, and in 1909 he bought a practice at Swansea, East Coast, Tasmania, where after a short residence his health was completely restored. He returned to England and took a course at Moorfields Eye Hospital, London, going back to Australia in 1913 and settling at Temora, New South Wales. After the war he went to Ceylon and practised at Nuwara Eliya, but returned to Australia in 1921 and settled at Meckering, where he practised until his death, exactly twenty years later. Archer Taylor belonged to the old school. He had a whimsical sense of humour and his mind did not track along the usual ruts: so that, always open to new impressions, he was in the forefront of any community with which he was associated. He was an ardent optimist, a loyal and generous friend, and a practitioner of the kind that is honoured with the confidence and love of his patients. He was a keen cricketer and an enthusiastic golfer almost to the time of his death.

Dr. THOMAS RONALD FULTON, who died suddenly on August 5 at Sutton-on-Sea, Lincolnshire, where he had been in general practice since 1936, graduated M.B., Ch.B. at Glasgow University in 1916. He immediately joined the R.A.M.C. and served in India and Mesopotamia with the rank of captain during the last war. In 1920 he became a partner with the late Dr. Alex. Day, M.B.E., and Dr. V. E. Badcock, M.C., at Wooler, Northumberland, where his practice extended far into the Cheviot Hills. He remained in Wooler until the end of 1935. For many years he was a member of the B.M.A., and was chairman of the North Northumberland Division in 1926-7. He was medical officer at the infant and child welfare centre at Wooler; and later on medical officer to the Mablethorpe Convalescent Home and Alford War Memorial Hospital while at Sutton-on-Sea. Dr. Fulton was a keen golfer and was president of the Wooler Golf Club for a number of years. He leaves a widow and three children.

We regret to record the death of Mr. MATTHEW LOGAN TAYLOR at his home in Park Quadrant, Glasgow, on August 20. Mr. Logan Taylor was the son of a doctor in Johnstone. He graduated at Glasgow University in 1897, and after passing through the house-physician and house-surgeon terms in the Western Infirmary became an assistant in the pathological department of the Western Infirmary and to the University professor of pathology, Sir Robert Muir. About the same time he was appointed surgeon to the out-patient department of the Royal Hospital for Sick Children and to the out-patient department of the Western Infirmary. Before settling down in Glasgow he was for a time in charge of a malaria expedition in Sierra Leone and the Gold Coast; that work was most favourably noticed by Sir Ronald Ross. During the war of 1914-18 Mr. Logan Taylor was Captain, R.A.M.C., in No. 3 Scottish General Hospital, Stobhill. For nine years (1915-24) he held the appointment of casualty surgeon at the Central Police Station. He was appointed visiting surgeon to the Western Infirmary in 1922. On his retirement under the age limit in 1940 he was appointed honorary consulting surgeon. For some years he acted as consulting surgeon at Dumbarton Cottage Hospital, and in the last few years held a similar appointment at Greenock Royal Infirmary. His contributions to medical literature were mainly along pathological lines. An article contributed to the *Journal of Pathology and Bacteriology* jointly with the late Prof. Teacher on a series of double malignant tumours, and another, published in the *Proceedings of the Pathological Society of Great Britain*, on a case of chorion epithelioma and adenocarcinoma of the testicle, were substantial contributions. His interest in pathology was maintained throughout the whole of his surgical career.

Field-Marshal Sir Philip Chetwode, chairman of the Executive Committee of the Red Cross and St. John War Organization, in a statement made last week, said that they had been officially informed that the Soviet Government would welcome the aid of the British Red Cross in supplementing its supplies of medical and other goods for the use of sick and wounded members of the Soviet armed Forces and for civilians injured by enemy action. The British Red Cross had accordingly allocated £250,000, which would be available to deal with all the immediate needs of Russia and of our other Allies. The organization is prepared to place the whole of its machinery at the disposal of any bodies that may wish to take advantage of its facilities for the purchase and transmission of supplies. Since the assumption of these great new responsibilities will add much to the financial requirements of the organization, Sir Philip Chetwode has asked Lord Iliffe, chairman of the Duke of Gloucester's Red Cross and St. John Fund, to issue a special appeal for funds.

Sir Robert Robinson, Waynflete Professor of Chemistry in the University of Oxford, has been awarded the first Paracelsus Gold Medal of the Swiss Chemical Society.

The McGill Medical Faculty, Montreal, opened its term with 400 students, which is considerably more than had been expected.

EPIDEMIOLOGICAL NOTES

Discussion of the Table

A further decline was recorded in the incidence of measles in England and Wales, 136 fewer cases being notified than in the preceding week. The notifications of whooping-cough also showed a substantial decline (319), the total of 2,710 cases being the smallest recorded this year. For the fifth consecutive week the incidence of diphtheria has increased; the increase is not yet general, however, being confined to the northern counties and Wales. The trend of this disease during the coming months will be of special interest in view of the immunization campaign. A slight rise was recorded in the incidence of scarlet fever, and the notifications have exceeded 1,000 for the first time since the end of May. In Scotland whooping-cough, after the large increase reported in the preceding week, declined; there were, however, increases in the notifications of diphtheria (20), measles (26), and scarlet fever (1).

Paratyphoid declined in England and Wales. A further 27 cases were notified from Bristol C.B. The only other area with a large number of cases was Liverpool C.B., with 14. In Scotland the 15 cases notified were 5 in excess of the number for the preceding week.

Dysentery

The 94 cases of dysentery notified in England and Wales, and the 67 cases in Scotland, represent an increase of approximately 50% on the totals of the previous week. The chief of the local outbreaks in England and Wales were those of Gloucestershire (Bristol C.B. 13) and Suffolk E. (Blyth R.D. 13). In Scotland the principal outbreaks were those of Aberdeen Burgh 8, Dundee 12, Lanark County 21, and Glasgow 12.

Cerebrospinal Fever

There were 118 cases of cerebrospinal fever in England and Wales, a decrease of 10 compared with the preceding week. The largest returns were those of Lancaster 22, Yorkshire, West Riding 15, and Glamorganshire 10. Although the number of cases notified in Scotland was unchanged during the past two weeks, the cases in Glasgow have risen from 6 to 10.

Polio-myelitis

An increase of 7 cases on the total for the preceding week was recorded in England and Wales, but the number of counties notifying the disease diminished by three. Berkshire with 5 cases (Maidenhead M.B. 4 and Cookham R.D. 1) had the largest county total. Four cases were notified in London (Bermondsey 1, Fulham 2, and Paddington 1). The only other registration: area with more than one case was Oxford C.B. 2. Three cases were reported from each of the following counties: Lancashire, Middlesex, Oxfordshire, and Somerset. No case was reported from Buckinghamshire. The 2 cases in Scotland were from the county of Ayr.

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended September 13.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included), (b) London (administrative county), (c) Scotland, (d) Eire, (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London), (b) London (administrative county), (c) The 16 principal towns in Scotland, (d) The 13 principal towns in Eire, (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

* Includes paratyphoid A and B for Northern Ireland.

† Includes primary form in figures for England and Wales, London (administrative county), and Northern Ireland.

‡ Owing to evacuation schemes and other movements of population, the birth and death rates for Northern Ireland are no longer available.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, W.C.1.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated.

Authors desiring REPRINTS of their articles must communicate with the Secretary, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors over-seas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

ADVERTISEMENTS should be addressed to the Advertisement Manager (hours 9 a.m. to 5 p.m.). Orders for copies of the *Journal* and subscriptions should be addressed to the Secretary.

TELEPHONE NO.—B.M.A. and B.M.J.: EUSTON 2111.

TELEGRAPHIC ADDRESSES.—EDITOR, *Atiology Westcent, London*; SECRETARY, *Medisecra Westcent, London*.

B.M.A. SCOTTISH OFFICE: 7, Drumshugh Gardens, Edinburgh.

QUERIES AND ANSWERS

Neurovascular Disorders

J. B. writes: I should be grateful for advice in the treatment of the following case. A man over 75 has suffered for six months from: (1) Numbness in right toes and loss of sensation to light touch. (2) Pain in right calf after three minutes' walk; there is complete relief from pain after two minutes' rest. (3) Mild angina on severe exertion (this for a few years). (4) Imperceptible pulses in posterior tibial arteries. The kidneys and other organs appear to be normal.

Function of the Vocal Cords

Dr. JOHN DONALD (Edinburgh) writes: Can one of your readers tell me where I may find in literature any information referring to Claudius Galen having been the first to suggest, about the year A.D. 200, that the generation of sound was in the vocal cords?

Recurrent Erysipelas

Dr. A. J. COLBY TINGEY writes in reply to E. C. A. (September 13, p. 392): Some years ago I was successful in treating a case of recurrent erysipelas with erysipelas phylacogen. This remedy is prepared by Messrs. Parke, Davis and Co., and is stated to be a sterile aqueous solution of bacterial derivatives from cultures of streptococcus and staphylococcus. Injected in a series of doses subcutaneously, it may be expected to produce some degree of immunity to the infection. My patient did not complain of any severe reaction. Autohaemotherapy is another method of treatment which has been favourably reported on in cases of streptococcal infections, including erysipelas.

Dr. F. F. HILLIER (Leeds) writes in reply to E. C. A. (September 13, p. 392): This is frequently due to some streptococcal infection in the nose, such as an infected sinus and/or a streptococcal fissure. Sinus infection may require an operation, but if there is a fissure at the corner of the nares, or at the bottom of the ear, it should be painted with a silver nitrate pencil, or 10% silver nitrate in 90% spirit. General artificial sunlight will help to improve her resistance.

Warts

Dr. F. J. ALLEN writes from Letchworth in answer to J. W. (September 13, p. 392): Is the headmaster of the school aware that warts are often due to an infection from garden earth? The most severe case I ever saw was in a gardener, who had the back of one hand entirely covered with them. As a child I used to play in a garden, handling the soil, and I then had several warts. In recent years, while doing much gardening, I had three warts on the palmar surface of the hands. One of them was large, fungating, and as painful as a corn on the foot. Radium seemed not to affect it, so I pulled out the enormously enlarged papilla and applied acid mercuric nitrate. The wart then healed in a week, and left a hardly perceptible scar.

Income Tax

Deductions from Salary

W. M. has been refused deductions for (a) "interest of £8 paid on hire purchase agreement for loan of £100 to purchase car," (b) replacement of medical books, and (c) interest on loan from a relative, the interest having been paid without deduction of tax.

* * (a) If the transaction is really one of "hire purchase"—the "interest" being paid to the future vendor of the car—the £8

can be regarded as a payment for hire, and will be allowable if, e.g., car allowances, running costs, etc., are allowable in W. M.'s circumstances. (b) This is strictly not allowable as the income is assessed under Schedule E. (c) Loan interest is not allowable; tax should have been deducted, and any claim for exemption, etc., made by the relative. Retrospective deduction can be arranged by agreement with the inspector, or if the relative can be shown to be exempt from income tax the inspector may be able to give W. M. the allowance for this year, if not for the future.

LETTERS, NOTES, ETC.

Treatment of Incontinence in Children over Four

Dr. J. HARTSILVER (Hove) writes: I have found the following method of treatment successful where other and more orthodox ones have failed. It would be of value if a more extensive trial could be made. It is assumed that any local cause has been excluded. First the urine should be examined. Then no fluids should be taken after 4.30 p.m. A thin night garment should be worn, and there should be as few bedclothes as possible. Curtains should be drawn back and window opened after the child is in bed. The child should be awakened every three hours to pass water whether he likes it or not, and a note taken of the times when the bed is wet; the child should then be made to pass water half an hour before such times. Next morning the draw-sheet should be pulled out, and if it is wet the child should be made with much firmness and kindness and without scolding to wash the sheet and his night attire. There is a nervous background to most cases of bed-wetting which should be investigated; it usually dates from some illness or mental upset.

Dust Infection in Wards

Lieutenant-Colonel H. A. MOFFAT, F.R.C.S., S.A.M.C., writes from South Africa: In all the articles which have recently appeared in the *Journal* on the above subject it is surprising that no mention is made of the use of vacuum cleaners instead of sweeping, and apparently no work has been done to test the effectiveness of their use. With vacuum cleaners the organisms on the floors are removed, not left stuck to the floors as by the oil methods. Further, blankets, etc., can be cleansed of dust and so of organisms. Hospitals appear to be behind the times in this respect, since private houses and office premises use these cleaners extensively.

Status of the Ship Surgeon

Dr. J. L. BARFORD (Redhill, Surrey) writes: The status of the Merchant Navy is once again "in the news"—How long, O Lord how long? May I urge that consideration be given to the establishment of a Royal Merchant Service Medical Service. During fifteen years in the Merchant Service I made endeavour, perhaps at times misguided, to raise the status of the ship surgeon. That it is "low" in the public estimate may be instanced by the fact that so popular a writer as Francis Brett Young typifies a ship surgeon as a "slovenly elderly man with a scurfy coat collar who drifts from place to place and has a voice heavily charged with whisky and orange peel." But apparently Mr. Brett Young found the pen more profitable than the stethoscope.

Rose-hips for Vitamin Syrup

Plans have been made by the Ministry of Health and the Department of Health for Scotland to harvest the vitamin wealth of Britain's hedgerows in the form of wild rose-hips, which are now well known to be particularly rich in vitamin C. Both garden and wild varieties are twenty times richer in this vitamin than orange; but hitherto these health-producing fruits have been allowed to go to waste. The collecting is being organized chiefly through schools, boy scouts, and girl guides, the Women's Institutes, and the Scottish Women's Rural Institutes. The hips, which must be ripe, can be gathered from wild or cultivated bushes, but the should be free from bits of stem and leaves. Haws, the red berries of the hawthorn or may tree, are not wanted, and care should be taken to avoid picking them. The gathering season extends until the end of October. The collecting organizations will supply the rose-hips in bulk to a number of firms who have agreed to pay for them at the rate of 2s. for 14 lb. (minimum 28 lb.), carriage forward. Small quantities should not be sent direct to the firms, but handed in to a collecting depot. Anyone who, however, is able to pick a large quantity can obtain the name and address of the nearest manufacturing firm from any of the collecting organizations or from the Women's Voluntary Services. As a result of the campaign it is hoped that some 500 tons of rose-hips will be converted into a tasty health-fortifying syrup for the benefit of babies, children, and adults. The syrup will be marketed at a reasonable price.

LONDON SATURDAY OCTOBER 11 1941

THE TREATMENT OF BACILLARY (FLEXNER) DYSENTERY WITH SULPHANILYLGUANIDINE

BY

DAVID E. W. ANDERSON, L.R.C.P., M.R.C.S., D.P.M.

AND

ROBERT CRUICKSHANK, M.D., M.R.C.P.

Cane Hill Mental Hospital, Coulsdon, and Group Laboratory, North-Western Hospital, Hampstead
(From the L.C.C. Public Health Services)

With a Note on the Preparation of the Drug, by James Walker, Ph.D., D.Phil.

National Institute for Medical Research, Hampstead

Search for an efficient intestinal antiseptic has in the past yielded poor results. *In vitro* tests of the bactericidal activity of antiseptics are no guide to their usefulness in suppressing pathogenic bacteria in the gut, for the substance must first pass the acid barrier of the stomach, withstand the action of bile and other intestinal juices, and exert a bactericidal action on the intestinal pathogens in a *milieu* of broken-down organic matter and hordes of saprophytic bacteria. Because the natural intestinal infections of man are so difficult to reproduce experimentally, the bactericidal or bacteriostatic activity of an antiseptic substance on the normal intestinal flora, particularly the coliform group, of experimental animals is probably the most useful index for its therapeutic trial in intestinal infections. Graham (1932) tested in this way a large series of substances which were powerfully bactericidal to the colon bacillus *in vitro*, but he failed to find any which produced an appreciable change in the intestinal flora when given by stomach-tube to mice. With the advent of the sulphonamides a fresh attack was made on the problem, and claims have been advanced for the therapeutic activity of different sulphonamide preparations against intestinal infections mainly on the basis of their bactericidal action on the typhoid-dysentery group of organisms *in vitro* or in the peritoneal cavity of injected animals. Since very large doses of typhoid or dysentery bacilli are usually required to kill a mouse infected intraperitoneally, the animal experiments were little better than tests in the tube. On the clinical side, different drugs, particularly those of the phenol series, have from time to time been popular as intestinal antiseptics. Lately, reports of an apparently beneficial result from the use of sulphapyridine or sulphathiazole on single or small groups of cases of typhoid and dysentery have appeared. As examples, Reider and Marberg (1941) treated 20 cases of acute bacillary dysentery at Haifa with 1 gramme of sulphapyridine three or four times daily for two to four days, and found that most of the symptoms disappeared in two days' time; while Bell (1941) reported good results in the treatment of 14 cases of Flexner and Sonne dysentery with a total average dosage of 5 grammes of sulphapyridine; in neither group was there an adequate control series. The objections to the use of these drugs as intestinal antiseptics are that they are gastric irritants and readily absorbed from the gut, so that if given in full doses they may not only upset an already irritable stomach

but because of the risk of dehydration and oliguria may produce severe toxic effects on the kidneys.

Properties of Sulphanilylguanidine

Marshall and his colleagues at Baltimore conceived the idea of using as intestinal antiseptic a sulphonamide compound which, although soluble in water and efficient chemotherapeutically, was poorly absorbed from the intestine. Of a number of such compounds which they had prepared, sulphanilylguanidine was chosen as being the most active against various bacteria. In 1940 Marshall *et al.* described the preparation of this drug, its pharmacology and toxicity, and its bactericidal or bacteriostatic activity on the intestinal flora of mice; and in a second paper (1941) its therapeutic value was demonstrated in a small series of dysentery infections. In their experience the toxicity of the drug for animals was of the same order as that of sulphapyridine and sulphathiazole, but as only a fraction of sulphanilylguanidine given by mouth was absorbed the risk of toxic effects with it seemed small. What absorption occurred was mainly from the small intestine, so that for a maximum therapeutic effect on the lower bowel infrequent large doses seemed likely to serve best. The absorbed fraction, part of it acetylated, was quickly excreted by the kidneys. Its most remarkable property was its power, when fed to mice, to reduce to scanty numbers the thousands or millions of coliform bacilli in the faeces. For clinical use these authors recommended an initial dose of 0.1 gramme per kg. of body weight followed by a maintenance dose of 0.05 gramme per kg. every four hours until the number of stools daily was four or less; then 0.1 gramme per kg. (0.05 gramme per kg. for adults) every eight hours for another three days. With such dosage they reported good results in 7 cases of acute bacillary dysentery treated within three days of onset; the therapeutic effect was variable in 10 cases treated later in the course of the disease. They quoted Lyon as having obtained excellent results in 15 out of 20 treated cases of severe dysentery, compared with 20 untreated control cases.

The value of a drug which, particularly in wartime, could be used for the control of dysentery was at once apparent to one of us (R. C.), and through the kindness of Sir Henry Dale a supply of sulphanilylguanidine was prepared by Mr. J. Walker, who appends a note on its preparation. Later we were fortunate in obtaining further supplies from

the American Red Cross Harvard Field Hospital through the kindness of Prof. J. E. Gordon and Dr. P. B. Benson, while a generous sample was also given us by Dr. Prescott of the Wellcome Foundation, Ltd.

Material and Methods

Although dysentery was the obvious choice of infection on which to test this new sulphonamide, the prevalent form of dysentery in the community was the usually mild Sonne infection, which, being self-limited and uncomplicated like bacterial food poisoning, did not lend itself to the therapeutic assessment of a new drug. However, with the good will of Dr. W. Allen Daley, Medical Officer of Health to the London County Council, and the sympathetic help of Prof. S. Nevin and Dr. S. A. Mann of the L.C.C. Mental Hospitals Pathological Service, arrangements were made to give the drug a therapeutic trial at Cane Hill Mental Hospital, where, opportunely, an epidemic of Flexner dysentery began in December, 1940, and continued with intermissions until June, 1941. Dysentery in mental hospitals is usually an endemic infection, often flaring up in the winter months and varying in severity from a mild diarrhoea to the most violent dysentery with frequent bloody stools and marked prostration. In this particular outbreak the infection was more severe and protracted than usual. Attempts to control its spread in the early stages by the use of a stock polyvalent Flexner vaccine were unavailing, and the prevalence and clinical severity of the outbreak may have been due to the introduction of a new type of Flexner bacillus along with a large influx of fresh patients. Once introduced into a ward the infection spread quickly to a large proportion of the inmates, who could not easily be taught the principles of personal hygiene. The prevalent type of organism was at first *B. dysenteriae* (Flexner Z) and later *B. dysenteriae* (Flexner X).^{*} The period of our investigation was from January to June, 1941.

All the patients were adults, of whom 130 were under observation. In this report, however, only patients who had both blood and mucus in their stools or who were bacteriologically confirmed to be suffering from Flexner dysentery were accepted for analysis. This reduced the number to 96, of whom 41 were treated with the drug and 55 were untreated controls. Their ages varied from 25 to 76 years; 55 were over 50 and many of them were in poor physical condition; 40 were males and 56 females.

Dosage of Drug.—The drug was given in powder form. It can be introduced as a suspension in water or milk; it has very little taste, and does not produce any nausea or vomiting. At first the prescribed dosage was 6 grammes a day in three doses of 2 grammes for four days, but after a preliminary trial this dosage was changed to 9 grammes a day in three doses of 3 grammes for two days, followed by 4 grammes a day in two doses of 2 grammes. If the diarrhoea was not controlled in four days the maintenance dose of 4 grammes a day was continued for one week. These are smaller doses than those recommended by Marshall *et al.*, but we were anxious to avoid the risk of any toxic effects from a new and clinically untried drug, and this dosage seemed to be therapeutically effective in most cases. However, later experience has convinced us that larger doses can safely be used, and may be advisable in the more severe cases of dysentery. A sample of blood was taken into oxalate twenty-four hours and again four days after starting treatment, in order to estimate the blood level of the drug. A morning specimen of urine was collected on the fourth day of treatment and examined for drug content, protein, crystals, casts, and cellular content. White cell counts were done on a number of treated and untreated cases. Bacteriological methods are discussed later. In all treated cases a liberal supply of fluids was insisted upon during the period of drug therapy, since sulphanilylguanidine, and particularly its acetylated derivative, might have irritative and toxic effects on the kidneys, similar to those produced by sulphapyridine and sulphathiazole, if adequate excretion was not maintained.

Clinical Results

While the principle of the alternate case was adopted in selecting cases for treatment, a fair number of patients did not develop the typical features of dysentery in the first day or two

of illness, but were later diagnosed on either clinical or bacteriological findings as Flexner infections. As a result treatment with the drug was reserved for an unduly large proportion of the more severe and classical infections. For purposes of analysis, therefore, the cases, both treated and untreated, were divided into two groups, labelled "severe" and "mild." The criteria of a severe case were a high initial temperature of 101° to 105° F., frequent stools (four to sixteen a day) containing both blood and mucus, and a prostrated toxic patient. The typical course of such a severe untreated case was an abrupt onset with high fever, headache, general malaise, severe abdominal pain, and in a few cases vomiting. Very soon there were frequent stools containing blood and mucus and accompanied by much tenesmus; the patient became quickly dehydrated and was very weak and toxic. Many of these cases had a typical, almost diagnostic, odour. The diarrhoea, usually with blood and mucus, continued for a week or ten days, and sometimes longer, and when the blood and mucus disappeared the motions often remained relaxed for a further few days. The temperature fell by lysis to normal in four to seven days; appetite improved after a week but convalescence was slow and protracted. In the milder case there was an initial rise of temperature to 99° to 102° F., abdominal pain and malaise, and relaxed stools, usually with blood and mucus, for two to five days. The temperature settled fairly quickly; abdominal pain disappeared, but malaise and anorexia persisted for a week or so, and the patient made a slow recovery.

Of 41 treated cases, 28 were classified as severe and 13 as mild; for the 55 untreated cases the distribution was 16 severe and 39 mild. Thus there was a much higher proportion of severe cases in the treated than in the untreated group. Two patients died among the 28 severe treated cases: one, aged 42, on the eighth day of infection despite a dramatic response to drug therapy; the other, aged 62, on the twenty-second day after making a good recovery from his dysentery. Three patients among the 16 severe untreated cases died: one, aged 29, on the third day of infection; one, aged 47, on the seventh day; and one, aged 60, also on the seventh day.

The criteria of clinical response to sulphanilylguanidine were: (1) a change in the character and frequency of the stools; (2) a rapid fall in temperature; and (3) the disappearance of toxic symptoms. A careful daily record was kept of the number and naked-eye appearance of the stools of every patient under observation, particular attention being given to the presence of blood and/or mucus. As the investigation proceeded it was felt that the number of motions a day was a less reliable guide to the response to treatment than the time in days of the disappearance of blood and mucus from the stools. In this connexion the day of disease on which chemotherapy was begun was an important factor in the reckoning. Among the severe cases the average time was 3.0 days from onset, ranging from two to five days, and in this group blood and mucus were present for an average period of 4.8 days, or 1.8 days after treatment was begun. In two patients blood and mucus persisted for more than a week after treatment was started. Among the severe untreated cases the average duration of blood and mucus in the stools was 6.8 days, or exactly two days longer than in the treated series. In the group of mild treated cases chemotherapy was begun at an average of 3.2 days from onset, and blood and mucus were present for 2.8 days from onset, so that in many cases blood and mucus had disappeared before specific treatment was given. The average duration for bloody, mucoid stools in the untreated mild group was 2.5 days. This criterion of clinical response was therefore valueless in the mild type of dysentery.

Temperature charts of all cases were kept for analysis, but a cursory examination of these showed that the difference in duration of pyrexia between treated and untreated cases was not likely to be statistically significant. The fact that in many cases treatment with the drug was not begun until the third day of illness precluded any striking effect on pyrexia, which in untreated patients was beginning to settle by the third or fourth day of disease. There were, however, outstanding cases with a critical fall of temperature apparently in response to drug therapy, just as there were untreated cases with pyrexia continuing at a fairly high level for five to seven days. It is impossible to say, with the limited numbers under review, whether these were chance occurrences or not.

^{*} We are indebted to the late Dr. W. M. Scott and to Dr. Marion Watson for the final identification of these strains.

The general response and behaviour of an ill patient under treatment with a new remedy is not readily susceptible to analysis, and the evidence must be assessed as objectively as possible by a physician with experience of the disease and with an adequate control series. At first, when the infection was rather mild and the initial dosage small, it was difficult to be positive about the beneficial effect of sulphanilylguanidine. Later, particularly with early treatment of the more severe cases, the clinical response to the drug was very definite and sometimes dramatic. Nursing staff became enthusiastic about its curative value. In a typical severe case improvement of the patient's condition was noted in twenty-four hours after giving the drug, and by the third day the patient was feeling much better with disappearance of toxic symptoms and return of appetite. Bowel movements became much less frequent within two days, though blood and mucus often persisted for three to four days. Most striking of all, convalescence was much shorter than in the untreated cases. In the milder infections, too, the treated patient was quickly sitting up, with good appetite, while the relaxed stools were followed by a period of constipation.

Relapses.—In the untreated series it was not uncommon for relaxed mucoid stools to continue for some time after the patient was clinically well, whereas the treated patient usually became constipated. But in the treated group four of the severe cases and one mild case had slight relapses, with blood and mucus in the stools for one or two days. These fresh attacks all occurred within a week after cessation of drug therapy, and were probably true relapses rather than reinfections. In only one of them was the Flexner bacillus isolated during the relapse.

Bacteriology

In the early stage of this investigation material for bacteriological examination was taken every day of the acute illness direct from the rectum by means of a rectal speculum and stout loop. The material obtained—usually mucus mixed with some faecal matter—was either planted immediately on to plates of MacConkey's medium or emulsified in warm saline and inoculated in the laboratory within one to two hours of taking the specimen. Suspicious colonies were picked next day, inoculated into the appropriate sugars for fermentation reactions, and tested by the slide-agglutination technique with the Flexner I and II polyvalent antisera of the Oxford Standards Laboratory. The results obtained by these methods were not very satisfactory, and towards the end of April a new medium became available which gave a much higher yield of positive results. This medium is a modification of the Difco S.S. formula, which is based on Leifson's (1935) work on the selective inhibitory action of sodium desoxycholate, citrate, and other chemicals on the normal intestinal bacteria. Full details of this desoxycholate-citrate agar and its usefulness in the isolation of the various intestinal pathogens will be published separately by Dr. Martin Hynes. Table I, prepared by Dr. Hynes, shows the results obtained with material from patients with Flexner infections, and demonstrates in particular the value of the new medium in isolating the pathogen during convalescence.

TABLE I.—A Comparison of the Isolation of *B. dysenteriae* (Flexner)

Day of Disease	No. of Specimens			% Positive	
	* M.C. + † D.C. +	M.C. - D.C. -	M.C. - D.C. -	M.C.	D.C.
1	16	4	0	80	100
2	19	15	1	84	97
3-7	5	10	3	28	83
>7		27	82	5	29

* M.C. = On MacConkey's medium.
† D.C. = On desoxycholate-citrate agar.

These figures refer to the total number of specimens examined on desoxycholate-citrate agar. So far as the results from individual patients are concerned the Flexner organism was isolated from 59 (61.4%) of the 96 patients in this series. During the period when Hynes's modification of the S.S. medium, or in a small number of cases the S.S. medium itself, was being used, 37 (92.5%) out of 40 patients yielded the Flexner organism; in 6 of these cases neither blood nor mucus was noted in the stools at any time, and others were suffering from

mild infections. It is only fair to state that during this period, when additional technical assistance was available in the hospital laboratory, the Flexner bacillus was isolated on MacConkey's medium in specimens from 27 (67.5%) out of 40 patients, which was a considerable improvement on the early results. Latterly specimens of faeces were being used as often as material obtained by the rectal loop and speculum.

Convalescent Carriers

With the new desoxycholate-citrate medium, which detects relatively small numbers of pathogens in the faeces, it became possible to assess the value of sulphanilylguanidine in eliminating Flexner bacilli from the bowel. While it is generally believed that the Flexner organism quickly disappears from the gut after an acute attack, there is little doubt, from epidemiological evidence, that convalescent carriers must exist, and these cases, together with cases of chronic dysentery, are mainly responsible for spreading the disease and for maintaining it as an endemic infection in a community.

If an intestinal antiseptic should prove to be not only beneficial against the acute infection but also able to prevent the convalescent carrier state or the development of chronic dysentery, it would be a great boon to the public health in general and to asylum communities in particular. With the help of the new medium an examination was therefore made for convalescent carriers of Flexner's bacillus in a series of treated and untreated patients, all of whom gave positive cultures in the first week of infection. Among 16 treated cases 3 gave positive cultures after the end of the first week; 2 of these were positive on the eighth or ninth day respectively, and neither of them gave positive specimens after a week's treatment with the drug. The third case had a mild relapse on the tenth day of disease, and gave two positive cultures following this fresh attack, which may have been a true reinfection. In contrast to these findings, among 17 untreated cases 8 were positive after the first week of infection, and 5 of them were still positive in the third week, 2 in the fourth week, and 1 in the sixth week. The difference between the two groups may be expressed in another way. Of 43 specimens of faeces examined from the 16 treated patients after the seventh day of disease, only 4 were positive, whereas 14 out of 54 similar specimens examined from the 17 untreated patients were positive. Thus sulphanilylguanidine given in the acute stage of a Flexner dysentery infection seemed to be effective in preventing the convalescent carrier state. It should be noted, however, that of the eight convalescent carriers in the untreated group three were initially mild infections, and it may be that such cases are more likely to become carriers than those with more acute infections. Our experience with sulphanilylguanidine in the treatment of Sonne dysentery, in which convalescent carriers are common (Cruikshank and Swyer, 1940), suggests that if the drug is given after the diarrhoea has ceased it is less likely to influence the carrier state. As the drug will now encounter much more organic matter and many more saprophytic bacteria in the bowel, larger doses than seem to be effective in the acute diarrhoeal phase may be required to eliminate the pathogens from the intestine of carriers. For the same reason, sulphanilylguanidine may not be an effective prophylactic in a ward outbreak of dysentery.

Absorption and Excretion

It was desirable to find out what proportion of sulphanilylguanidine was being absorbed from the intestine of patients with acute bacillary dysentery and whether it was readily excreted by the kidneys. The concentration of the drug in the blood twenty-four hours and four days after starting treatment and the urinary concentration on the fourth day were therefore estimated on 28 patients by the method of Hynes (1940). In addition an estimate of the total amount of drug excreted in the urine was made in three patients in order to determine more exactly what proportion of the total dosage given by mouth was absorbed and excreted. The average concentration of the drug in the blood, examined about two hours after the last dose of 2 or, more often, 3 grammes and a total amount of 6 to 12 grammes in the previous twenty-four hours, was 1.55 mg. of free sulphanilylguanidine and 2.57 mg. of total drug per 100 c.c.m.; on the fourth day, after a dosage of 4 grammes in the previous twenty-four hours, the corresponding blood levels were 0.74 and 1.28 mg. per 100 c.c.m. The drug concentra-

tion at twenty-four hours varied for free sulphanilylguanidine from 0.5 to 3 mg. and for total drug from 0.75 to 6 mg. per 100 c.cm.; at four days the corresponding extremes were 0.25 to 1.75 mg. free drug and 0.5 to 2.5 mg. total drug per 100 c.cm. These figures, when compared with the blood levels after similar doses of the other sulphonamides, show that sulphanilylguanidine is poorly absorbed from the bowel and that the amount absorbed bears some relation to the dosage given. The urinary concentration of sulphanilylguanidine on the fourth day after treatment averaged 94.3 mg. per 100 c.cm. for free drug and 150.2 mg. per 100 c.cm. for total drug. The highest concentration, 240 mg. of free drug and 300 mg. of total drug, occurred in the patient who gave the highest blood concentration—namely, 3 and 6 mg. per 100 c.cm. Thus the urinary findings indicated that the absorbed moiety was being readily excreted. The rate of excretion could best be appreciated from the drug concentrations in the measured twelve-hourly collections made on three patients during and immediately after the period of drug therapy. The findings in one of them are given in Table II as an example which was closely paralleled by the other two.

TABLE II.—*The Urinary Excretion of Sulphanilylguanidine after Doses of 9, 9, 4, and 4 Grammes daily from April 12, 1941*

Date	Time	Volume	Sulphanilylguanidine per 100 c.cm.	
			Free	Total
April 12-13	8 a.m.-8 p.m.	32	30	35
	8 p.m.-8 a.m.	12	170	260
.. 13-14	8 a.m.-8 p.m.	16	120	220
	8 p.m.-8 a.m.	14	150	250
.. 14-15	8 a.m.-8 p.m.	24	60	150
	8 p.m.-8 a.m.	14	110	190
.. 15-16	8 a.m.-8 p.m.	32	70	105
	8 p.m.-8 a.m.	22	110	180
.. 16-17	8 a.m.-8 p.m.	16	60	170
	8 p.m.-8 a.m.	10	100	110
.. 19..	8 a.m.-8 p.m.		10	15
	8 p.m.-8 a.m.			

It will be noted that the concentration rose to a maximum between twelve and thirty-six hours after beginning treatment, fell to a lower level on the third and fourth days when the dosage was smaller, and quickly dropped to a very low concentration after treatment was stopped. There is therefore no evidence that the drug is retained in the tissues for any time after absorption. The proportion of acetylated drug varied both in the blood and in the urine between an eighth and a half of the total, and, as with other sulphonamides, there was no clue as to why certain patients conjugate a large proportion and others very little.

In three cases a rough estimate was made of the total amount of drug excreted in the urine during and immediately after the period of treatment. The calculation, based on the total volume of urine and on concentrations of the drug in twelve-hour collections, gave amounts of 7.5, 8.5, and 13 grammes respectively out of a total of 26 grammes ingested by each patient. If these figures represent the actual amount of drug absorbed, then about one-half to two-thirds must remain in the intestine, to be excreted in the faeces. Estimations were made of the drug concentration in twelve specimens, from three different patients, of fluid or semi-solid stools passed during the period of treatment; the concentration varied from 10 mg. (in a very watery specimen) to 700 mg. per 100 c.cm. Actually only half of the specimens gave concentrations above 200 mg. per 100 c.cm., which is the saturation level of the drug. These figures are lower than those quoted by Marshall and his colleagues (1941), and might be regarded as an indication for bigger doses than were used in this investigation.

Toxicity

With the doses used and the small amount of drug absorbed systemic toxic effects such as occur with the other sulphonamides were not anticipated with sulphanilylguanidine. In fact with one exception no clinical evidence of toxicity was noted: a rash of morbilliform type occurred on the twelfth day of treatment in a patient who, because of persistent diarrhoea, had been given a total dosage of 58 grammes of the drug (9 grammes daily for two days and 4 grammes daily for ten days). Marshall

et al. (1941) commented on the absence of toxic effects in their series of 25 treated children: in a group of 25 adults treated with the drug there were two cases of drug fever and one of mild haemolytic anaemia. The complication that seemed most likely to occur, as a result of the dehydration and diminished urinary excretion, was deposition of the drug in the urinary tract, with consequent irritative or obstructive effects. In no patient in our series, however, was there oliguria or urinary suppression, and no one complained of lumbar pain. Laboratory examination of the fourth-day specimen of urine of 28 patients showed a trace or slight trace of protein in 5: it seemed likely that this finding was related to the infection rather than to the drug. Epithelial cells and leucocytes were seen in about half the specimens, which were all non-catheter; neither red blood cells nor casts (apart from occasional hyaline casts) were noted in any specimen of urine. Crystals, usually in the shape of narrow rectangles, were present in the urinary deposits of 21 out of 28 patients: sometimes scanty, sometimes abundant, the presence and the amount of crystalline deposits bore a close relation to the urinary concentration of the drug. In this series of specimens crystals were usually present when the urinary concentration of free drug was over 100 mg. per 100 c.cm., which seemed odd in view of Marshall's statement that the drug is soluble to 200 mg. per 100 c.cm. Test-tube experiments were therefore made in order to find out the saturation level of the drug in urine of pH 5.6. At body heat (37° C.) the solubility was 175 mg. per 100 c.cm., at room temperature (18° C.) 150 mg., and at 4° C. 125 mg. Thus our finding of crystalline deposits with low urinary concentrations of the drug was probably related to the fact that many specimens of urine in this investigation were sent by post to the group laboratory during the winter months; solubility may also be affected by a high level of other inorganic constituents such as would be present in concentrated urine from febrile patients. Where the urinary concentration of the drug was high—as, for example, in the second-day specimens of the patients whose urine was examined daily—sheaves of narrow pointed crystals rather like those of tyrosine were seen in the urinary deposit and were regarded as the crystals of the acetylated drug. Similar crystals were observed in the urine of treated patients not in this series. One of these was a woman aged 86 with a severe *Salmonella reading* infection who was not benefited by large doses of sulphanilylguanidine and who died on the eleventh day of her infection. Histological examination of the kidneys showed marked degeneration of the tubular epithelium but no evidence of any irritative reaction. Nevertheless where large doses of the drug are being given it seems a wise precaution to insist on a liberal fluid intake.

White cell counts were done on 12 treated cases at the end of the period of drug therapy and in 9 untreated control cases. In the treated group the counts varied from 7,900 to 13,000 cells per c.mm., with an average count of 9,666; in the control group the extremes were 7,300 and 14,800 cells per c.mm., with an average of 9,733. Two treated patients with counts of 12,000 at the onset of infection were retested two weeks later and had counts of 9,800 and 10,200 cells per c.mm. respectively, which merely suggests that there is a slight leucocytosis at the onset of an acute dysentery. When it is remembered that more than half of the patients in the series were over 50 years of age, with a natural tendency to impairment of function, it is obvious that sulphanilylguanidine in the doses given has practically no toxicity for the tissues.

Conclusions

Sulphanilylguanidine, a new intestinal antiseptic, has been used in the treatment of 41 adult cases of acute bacillary (Flexner) dysentery with beneficial results, particularly in the more severe infections. A series of 55 cases in the same epidemic served as controls. While a dosage of 3 grammes three times a day for two days followed by 2 grammes twice a day for two to five days was therapeutically effective, larger doses are safely tolerated and may be advisable in severe or refractory infections.

Treatment with the drug in the acute stage of the infection apparently helped to prevent a convalescent carrier state, which was present in about half of a bacteriologically controlled untreated group.

Sulphanilylguanidine probably owes much of its effectiveness as an intestinal antiseptic to its poor absorption from the intestine, since one-half to two-thirds of the drug remains unabsorbed.

Blood and urinary concentrations of the drug were low relative to the dosage given, and toxic effects were conspicuous by their absence. Since crystalline deposits occur in the urine with concentrations over 175 mg. per 100 c.cm., an adequate fluid intake and output should be maintained to avoid local toxicity or irritation in the urinary tract, although there was no evidence of any such effect in this series of treated cases.

The use of a new culture medium, desoxycholate-citrate agar, resulted in the isolation of *B. dysenteriae* (Flexner) from a high proportion of both typical and atypical infections. Its superiority over MacConkey's medium was most noticeable in the isolation of the pathogen during convalescence.

The combination of an efficient intestinal antiseptic and a culture medium which will readily detect mild infections and convalescent carriers may be instrumental in eliminating dysentery from mental hospitals.

We wish to thank Dr. G. A. Lilly, medical superintendent of Cane Hill Hospital, for facilities and encouragement throughout this investigation, and the technical staff of the hospital and group laboratories for their help.

THE PREPARATION OF SULPHANILYLGUANIDINE

It appears that sulphanilylguanidine (I) was first obtained by Buttle *et al.* (1938), who, from its mode of formation, unwittingly ascribed an erroneous constitution to their product (Dewing and Smith, 1941). The compound was first described as such by Robin and his co-workers (1940), who encountered it accidentally in the course of their study of the synthesis of heterocyclic derivatives of sulphanilamide. These authors, for identification purposes, then obtained the substance by reduction of the nitro group in *p*-nitrobenzenesulphonylguanidine (II), which they synthesized (cf. Winnek, 1940, 1941). A few weeks later Marshall and his colleagues (1940) published a description of a large-scale preparation of sulphanilylguanidine, and their method was followed in the present work. Condensation of acetyl-sulphanilyl chloride with guanidine nitrate in the presence of a large excess of sodium hydroxide yields acetyl-sulphanilylguanidine (III), which is subsequently hydrolysed with hydrochloric acid to free sulphanilylguanidine:

Two points of interest emerge and deserve comment. As obtained initially, the acetylsulphanilylguanidine (III) forms a somewhat pasty white solid which tenaciously retains water. Drying is a very slow process under the ordinary conditions (hot oven at 90° C., or vacuum desiccator, etc.), and furnishes apparent yields of the same order as those quoted by Marshall *et al.*—namely, 65 to 70% of theory. Hydrolysis of this product yielded free sulphanilylguanidine also in the amount reported by Marshall *et al.*—namely, 45 to 60% of theory. The process of drying can, however, be greatly accelerated by washing the cake of crude acetyl derivative on the filter with small volumes of spirit and then ether, in which solvents the

compound is insoluble. Drying in the hot oven at 90° C. then gives an absolutely dry product in an hour or two, and, on account of the more efficient drying, the yields obtained at this stage appear to be somewhat smaller—namely, 59 to 62% of theory. On the other hand, hydrolysis of the acetyl derivative dried in this way gave free sulphanilylguanidine in the improved amounts of 61 to 72% of theory.

Tests for acute and chronic toxicity of this preparation on mice gave results very similar to those reported by Marshall *et al.* (1940).

A TELLURITE-IRON-ROSOLIC ACID MEDIUM SELECTIVE FOR *B. DYSENTERIAE* (FLEXNER)

BY

W. JAMES WILSON, M.D., D.Sc.

AND

E. M. McV. BLAIR, M.Sc., Ph.D.

(From Public Health Laboratories, Queen's University, Belfast)

Dysentery bacilli, unlike those of the typhoid-paratyphoid groups, have not shown any peculiar characters enabling the investigator to devise a medium which, while inhibiting the growth of other organisms, allows them to develop and be readily identified.

On litmus lactose agar and on the media of MacConkey, Conradi-Drigalski, and Endo the unrestrained growth of *B. coli* leaves little place on the plates for the development of dysentery bacilli, so that their successful isolation is usually possible only in the early acute stages of the disease and when the stools are planted out within a few hours of their collection. To the antiseptic action of such dyes as malachite green, methyl green, victoria green, brilliant green, fuchsin, crystal violet, and gentian violet dysentery bacilli are more sensitive than most strains of *B. coli* (Churchman, 1912, 1913; Krumwiede and Pratt, 1914; Kligler, 1918). The new Difco Bacto S S agar specially devised for the isolation of *Salmonella* and *Shigella* strains is designed to meet a long-felt want, a want which may also be satisfied by the medium described in this paper.

The Action of Sodium Tellurite

In the course of an investigation of the suitability of a modified bismuth sulphite medium for the selective growth of Flexner's bacillus, addition of sodium tellurite was found to reduce the growth-inhibitory action both of the bismuth and of the tellurite.

We have shown in the development of our bismuth sulphite medium that the addition of iron salts enabled the *B. typhosus* to develop while the growth of many other organisms continued to be suppressed (Wilson and Blair, 1927). It was this experience which led us to try a combination of tellurite and a ferric iron salt. Having found the bismuth sulphite media unsuitable for use with tellurite, we tried the addition of tellurite to MacConkey's medium, and discovered that the addition of 0.5 c.cm. of a 1% watery solution of sodium tellurite to 100 c.cm. of the medium completely inhibited the growth of nine strains

of *B. lactis aerogenes* and nineteen of twenty-one strains of *B. coli*, whilst all of six strains of Flexner's dysentery bacilli showed some growth, varying from a few isolated colonies to confluent growth. It was clear that tellurite showed possibilities of being used in a medium selective for Flexner bacilli. However, the concentration necessary for the suppression of *B. coli* was sufficient to prevent the growth of all but the most resistant strains of *B. dysenteriae* (Flexner); in other words, instead of hundreds of colonies or a confluent growth, only a few isolated colonies developed. It was then found that the addition of 2 c.cm. of a 4% watery solution of iron citrate scales to 100 c.cm. of the MacConkey tellurite medium allowed a rich growth of the dysentery bacilli and that the suppression of *B. coli* continued. How the iron salt acts, whether by precipitating some of the tellurite or by a process of oxidation, is uncertain. It would seem that the iron salt converts the tellurite into a form which permits rich growth of Flexner bacilli and yet inhibits the growth of *B. coli* to a very large extent. There is an optimum proportion in the ratio of tellurite to iron, and as the result of numerous experiments we found that for 0.5 to 1 c.cm. of a 1% potassium tellurite solution the amount of a 4% watery solution of iron citrate should be 2 c.cm., or of a 4% watery solution of iron alum 1 c.cm. ($K_2SO_4 \cdot Fe_2(SO_4)_3 \cdot 24H_2O$). The basis of our medium is ordinary nutrient agar consisting of distilled water 1,000 c.cm., peptone 10 grammes, Lemco 5 grammes, sodium chloride 5 grammes, powdered agar 20 grammes. The reaction is adjusted to pH 7.4. The nutrient agar is sterilized under pressure and is not filtered.

Constituents of the Medium Used

A medium which we employed in many of our experiments, and with which we were successful in isolating Flexner dysentery bacilli from two samples of faeces sent by post, is made as follows:

0.5 gramme of sodium tauroglycocholate and 0.5 gramme of lactose are dissolved in about 10 c.cm. of boiling water in a 100-c.cm. wide-necked flat-bottomed extraction flask; then melted nutrient agar cooled to 60° C. is added up to the 100 c.cm. mark, followed by 0.5 c.cm. of 1% potassium tellurite, 2 c.cm. of 4% iron citrate, and 0.5 c.cm. of 1% neutral red watery solution.

On the surface of this medium colonies of Flexner's bacillus are yellowish, and any strains of *B. coli* that are not suppressed are reddish. In practice we found that stools which show few colonies of *Streptococcus faecalis* on ordinary MacConkey provided abundant tiny colonies on this medium. There was no danger of confusing these colonies and those of Flexner, but it was obvious that their suppression would be a great advantage. After numerous trials of various substances we found that the addition of 0.5 c.cm. of 1% rosolic acid dissolved in absolute alcohol to 100 c.cm. of the tellurite medium secured the desired result. This suppression of *Str. faecalis* by rosolic acid we have confirmed by the examination of over sixty stools and the employment of pure cultures of *Str. faecalis*. Our results confirm those of Bronfenbrenner, Schlesinger, and Soletsky obtained in 1920. These authors found that rosolic acid, or a mixture of rosolic acid and china blue, when added to 100 c.cm. of media to the extent of 0.25 c.cm. of a 2% solution of rosolic acid in 50% alcohol, allowed the growth of colon, typhoid, and dysentery bacilli while suppressing that of Gram-positive bacteria, including *Str. faecalis*.

In our medium the tellurite-iron complex inhibits many coliform organisms, but allows rich growth of Flexner's dysentery bacilli, and the rosolic acid acts not only as an indicator but as an agent for the suppression of *Str. faecalis*

and other Gram-positive bacteria. The tellurite-iron-rosolic acid medium is highly selective for Flexner's dysentery bacilli. On this medium the growth of typhoid-paratyphoid bacilli, Sonne's bacillus, and cholera vibrios is completely suppressed, as is that of twenty strains of *Salmonella* food-poisoning organisms kindly supplied to us by Dr. St. John-Brooks from the National Collection; these included such strains as *aertrycke* (mutton), *chesier*, *chaco*, *berlin*, *binns*, *derby*, *dublin*, *heidelberg*, *hirschfeld*, *para C*, *kapsover*, *kunzendorf*, *morbificans-bovis*, *london*, *limerick*, *newport*, *panama*, *stanley*, *senftenberg*. The growth of most strains of *B. coli* and *B. lactis aerogenes* is completely inhibited or is very scanty.

In the recent examination of fifty stools we found that heavy inocula of faecal emulsions did not, as on MacConkey plates, lead to confluent growth of *B. coli* but to the formation of discrete colonies, which were sometimes few and sometimes numerous. There was no difficulty in isolating the dysentery bacillus when it was mixed with the faecal emulsion. On the medium few non-lactose-fermenting bacteria developed, apart from Flexner's dysentery bacilli; such as developed have been found to belong to the *Proteus*, *Alcaligenes*, and *Pyocyaneus* groups, and can be distinguished from dysentery bacilli in that they form pink colonies, larger, more raised, and with a centre more opaque than that of the more translucent colonies of Flexner's bacillus.

Experimental Technique

In our experiments we employed five strains of Flexner's bacillus (V, W, X, Y, Z) obtained from the National Collection of Type Cultures and five strains recently isolated in Northern Ireland. All the strains grew well on the medium which for some time past we have found most satisfactory. It is prepared as follows:

To 100 c.cm. of melted nutrient agar cooled to 60° C. in a flask are added 0.5 c.cm. of 1% rosolic acid dissolved in absolute alcohol, 1 c.cm. of a 4% watery solution of iron alum, and finally 3 c.cm. of a lactose-tellurite solution. The latter solution is made by boiling 20 grammes of lactose in 100 c.cm. of distilled water, cooling the solution, and then dissolving in it 0.1 gramme of potassium tellurite. It is necessary to dissolve the tellurite in the cold, otherwise reduction occurs. This lactose tellurite solution keeps for weeks, the tellurite being an effective preservative against bacteria, but not against moulds: growth of the latter can be prevented by the addition of 3% of ether and keeping the bottle tightly stoppered.

When the contents of the flask containing the medium have been thoroughly mixed they are poured out into Petri dishes and allowed to set with the lids removed. A large loopful of a thick faecal emulsion in peptone water is spread over the surface of the plate and allowed to dry in the air. After incubation at 37° C. for eighteen hours the pink colonies of Flexner's bacillus are readily distinguished from any yellow colonies of resistant *B. coli* which may have developed. Flexner's bacillus forms alkaline colonies which may be tested at once on a slide for agglutination with a polyvalent Flexner agglutinin serum. It is also easy to subculture suspicious colonies on to MacConkey's agar and test the agglutinability of the growth. For further proof of the nature of the organism cultures are made in small test tubes containing mannitol and glucose dissolved in peptone water with Andrade's reagent as indicator; the addition to these tubes of a small amount of melted and cooled to 45° C. is a ready method of detecting the absence of gas formation.

When this paper was being completed two stools containing blood and mucus arrived, having been posted

previous day. Both of these specimens on the tellurite-iron-rosolic acid medium showed hundreds of colonies of Flexner's bacillus and absolutely no *B. coli*, whereas the same emulsion on MacConkey's plates yielded a profuse growth of *B. coli* and no recognizable colonies of *B. dysenteriae*.

Summary

Lactose nutrient agar containing, per 100 c.c.m., 0.5 c.c.m. of a 1% alcoholic solution of rosolic acid, 0.5 c.c.m. of a 1% solution of potassium tellurite, and 1 c.c.m. of a 4% solution of iron alum provides a medium on which Flexner's *B. dysenteriae* grows profusely, whereas there is great inhibition of most strains of *B. coli* and *B. lactis aerogenes*. The growth of *Salmonella* food-poisoning organisms, typhoid and paratyphoid bacilli, Sonne's bacillus, and cholera vibrios is suppressed.

A NEW SULPHONAMIDE (SULPHONAMIDE E.O.S.)

ITS PHARMACOLOGY, CHEMOTHERAPY, AND CURATIVE VALUE IN MENINGOCOCCAL MENINGITIS

BY

N. MUTCH, M.A., M.D., F.R.C.P.

Senior Physician to Guy's Hospital; Sector Adviser in Medicine,
E.M.S.; Director of Department of Therapeutics and
Pharmacology, Guy's Hospital Medical School

Although some thousands of sulphonamide derivatives have now been prepared and investigated, very few have displayed any outstanding therapeutic qualities which would justify their general adoption in preference to the simple parent substance sulphanilamide or its popular variant sulphapyridine. The clinician desires something more than an active chemotherapeutic agent. He asks for the means of easy administration to patients of all ages and in all conditions and for freedom from side-actions which are either distressing or dangerous. The new compound employed in this investigation* is freely soluble in water, and 50% w/v solutions are easily obtained. It dissolves to form an almost tasteless preparation with a faintly acid reaction which can be reduced to one of absolute neutrality without precipitation or loss of stability. The treatment of infants and of fastidious, comatose, vomiting, or diarrhoeal patients is therefore easily carried out with solutions given by mouth, nasal tube, rectal tube, or intravenous drip. The familiar 0.5 gramme tablet can be reserved for routine use. In these respects it contrasts favourably with sulphanilamide, which is relatively insoluble in water, with sulphapyridine, which is much more insoluble still, and with sulphapyridine sodium, which, although freely soluble, forms a strongly alkaline solution approximately equivalent in reaction to decinormal caustic soda. Sulphonamide E.O.S. possesses the further attractive feature of low toxicity, and its administration does not lead to the formation of such highly insoluble bodies as the acetylated compounds, which tend to crystallize in the urinary passages when sulphapyridine or sulphathiazole is used (Leedham-Green, 1941).

* The material used in this investigation was supplied by the Research Department of Imperial Chemical Industries Ltd.

Chemistry and Fate in the Body

The substance was first described by Green and Coplans (1940), who identify it as sulphonamide ethyl-alpha-sulphonate,

The side chain was chosen with two deliberate intentions—namely, that of reducing the basicity of the original sulphanilamide and so reducing its toxicity, and that of furnishing a link (as indicated by the arrows) which could easily be broken in the body by hydrolysis, with the liberation of the parent nucleus. In aqueous solution it is stable at room temperature, but hydrolysis occurs on boiling, with the formation of sulphanilamide, acetaldehyde, and sodium bisulphite. Decomposition proceeds more quickly in the presence of acids or alkalis, and is accelerated very greatly indeed by oxidizing reagents such as iodine or hydrogen peroxide. Hydrolysis at body temperature and at pH concentrations which are known to occur in the alimentary tract is relatively slow. The pertinent data given in Table I were furnished by the late Prof. A. G. Green.

TABLE I.—Hydrolysis of Sulphonamide E.O.S.

Reaction of Solution (2% E.O.S.)	% E.O.S. hydrolysed in 3 Hours at 27° C.
N/10 HCl (hyperchlorhydria)	4.0
N/20 HCl (normal test-meal peak) ..	2.8
Neutral	0.7
0.2% NaHCO ₃	1.8

Throughout this range more than 95% of the drug remains unaffected at the end of three hours, and during this period a large proportion of the drug is absorbed. After absorption hydrolysis proceeds much more rapidly.

A 50% solution w/v was injected intravenously (dose 5 c.c.m. = 2.5 grammes E.O.S.). Of this only 16% could be recovered unchanged from the urine, and even during the first thirty minutes about one-half was excreted as sulphanilamide or as acetyl-sulphanilamide, the side chain having been removed from the original drug (Table II).

TABLE II.—Intravenous Administration of Sulphonamide E.O.S. (Man). (Dose, 2.5 grammes in 5 c.c.m.)

Interval after Administration (Hours)	Rate of Urinary Excretion	
	Unsplit Sulphonamide E.O.S. (Mg. per ½ hour)	Total Sulphonamide, expressed as Sulphanilamide (Mg. per ½ hour)
0-1	220	471
1-1½	120	317
1½-2	40	—
2-2½	10	—
2½-3	0	69
3-6	0	115

TABLE III.—Administration of Sulphonamide E.O.S. by Mouth (Man). Dose, 4 grammes dissolved in water taken between meals at 11 a.m.)

Interval after Administration	Vol. of Urine (c.c.m.)	Rate of Urinary Excretion	
		Unsplit Sulphonamide E.O.S.	Free Sulphonamide, expressed as Sulphanilamide (mg. per ½ hour)
0-20 minutes	15	Small amount	Trace
20-45 "	15	" "	3.0
45-60 "	15	" "	15.4
1-1½ hours	25	" "	15.5
1½-2 "	25	" None "	17.0
2-3 "	32	" "	12.0
3-5 "	45	" "	11.8
5-7 "	50	" "	8.6
7-9½ "	60	" "	9.2

The excretion of sulphonamide E.O.S. ceased after two hours, but excretion of considerable amounts of sulphanilamide continued for many hours. The rate of excretion was substantially modified by variations in urinary flow. Excretion was decidedly more rapid during water diuresis. This rapid hydrolysis in the

body can be ascribed provisionally to the presence of oxidizing agents such as tissue oxidases and oxyhaemoglobin.

When a single dose is given by mouth, excretion of unsplit E.O.S. begins within twenty minutes and continues for an hour and a half, after which time E.O.S. can no longer be found in the urine, but sulphanilamide and its acetylated derivative are excreted in substantial amounts throughout the day. The peak rate of total sulphonamide excretion occurs between one and a half and two hours after administration of the drug (Table III). Of the original 4 grammes only about 30 mg. could be found in the urine in its original form. Hydrolysis is therefore almost complete.

With the slower rate of absorption following administration by rectum it was impossible to find any unsplit E.O.S. in the urine, and the peak rate of sulphanilamide excretion was much delayed (Table IV). Nevertheless the drug is therapeutically effective when given in this way (Case 19, Table VIII).

TABLE IV.—Rectal Administration of Sulphonamide E.O.S. (Man). (Dose, 4 grammes in 8 c.cm.)

Interval after Administration (Hours)	Vol. of Urine (c.cm.)	Rate of Urinary Excretion	
		Unsplit Sulphonamide E.O.S.	Total Sulphonamide expressed as Sulphanilamide (Mg. per $\frac{1}{2}$ hour)
0-1	55	Nil	17
1-1 $\frac{1}{2}$	30	"	12
1 $\frac{1}{2}$ -1 $\frac{3}{4}$	23	"	21

The analytical methods used were:

Sulphanilamide+E.O.S.=free sulphonamide
Sulphanilamide+E.O.S.+acetylated sulphanilamide } Marshall's method (Marshall *et al.*, 1937)
=total sulphonamide

Unsplit sulphonamide E.O.S.:

The following method was devised by A. G. Green: To 25 c.cm. of urine add 5 c.cm. of 10% barium chloride solution and filter. To filtrate add 2 c.cm. of concentrated hydrochloric acid and filter again if necessary. To the clear solution add 1 c.cm. of N/1 sodium nitrite (7.2% solution). If free sulphonamide E.O.S. is present a further turbidity or precipitate will form and can be compared with a standard control.

Conclusions.—Sulphonamide E.O.S. is probably adsorbed unchanged when given by mouth or rectum. In the body it is rapidly hydrolysed, but during therapeutic schemes of routine four-hourly doses small amounts of unsplit drug persist in the cerebrospinal fluid throughout the inter-dose period. When administered orally it is excreted in the urine to a small extent unchanged, but mainly in the form of sulphanilamide with a small proportion of the acetylated

derivative of sulphanilamide. On intravenous injection hydrolysis to the extent of 25% occurs within an hour and is complete after two hours. Opportunities for an individual therapeutic action are offered by (1) the production of sulphanilamide *in situ* in the blood and tissues, and possibly in the bacterium itself; (2) the independent action of the unsplit drug; (3) the rapid rate of absorption from the upper alimentary tract and rectum.

Experimental Therapeutics

The toxicity of sulphonamide E.O.S. has been assessed in terms of lethal dose administered to animals by mouth and by clinical survey of phenomena appearing during therapeutic administration in man. Values given by various observers for the toxicity of sulphanilamide measured in terms of L.D.50 range between 60 and 80 mg. for the 20-gramme mouse. Such figures are influenced by the strain of mouse used. In the present research female albinos were employed and parallel doses of sulphanilamide suspension and sulphonamide E.O.S. solution were administered by oesophageal tube. Deaths were recorded seventy-two hours later, when surviving animals appeared to be normal. For sulphanilamide L.D.50 was found to be 70 mg. per 20-gramme mouse. For sulphonamide E.O.S. it was 200 mg., giving a toxicity ratio on a gravimetric basis of about 1:3 in favour of sulphonamide E.O.S. The relative molecular weights of the two substances must be taken into consideration:

$$\frac{\text{Mol. wt. E.O.S.}}{\text{Mol. wt. sulphanilamide}} = \frac{302}{172} \text{ i.e., approximately } \frac{7}{4}$$

7 grammes of E.O.S. are therefore equivalent in nuclear content to 4 grammes of sulphanilamide. Making the appropriate correction, the toxicity ratio becomes 1:1.6, showing that the amount of sulphonamide nucleus which can be given in the form of sulphonamide E.O.S. is substantially greater than that which can be given with equal safety in the form of sulphanilamide. Further toxicity tests and an experimental investigation of the curative action of the drug on infected laboratory animals were carried out by Dr. M. Coplans as follows:

(i) Acute Infections

Streptococcus pyogenes (from the National Collection of Type Cultures, Group A—Griffith No. 5493)

Albino mice, and doses calculated per 20 grammes weight: 5 million streptococci injected intraperitoneally; 1 c.cm. 5% aqueous solution (neutral) E.O.S.=25 mg., given subcutaneously 1/2 hour after inoculation and repeated daily.

21 mice inoculated and treated:

3, duration of treatment 2 days. All died on ninth day.
18, duration of treatment 10 to 20 days. 11 survived, and cultures taken between 46th and 58th day were all negative.

Controls:

18 mice inoculated and not treated. All dead within 17 $\frac{1}{2}$ hours and organism recovered from heart blood and peritoneal fluid.
18 mice treated for 10 to 20 days but not inoculated. 15 survived (3 died on 7th, 18th, and 27th days).

Pneumococcus Type III (from the National Collection of Type Cultures Type III—Griffith No. 2438)

Albino mice, and doses calculated per 20 grammes weight: broth culture (100 \times M.L.D.) intraperitoneally; 0.5 c.cm. aqueous solution of E.O.S.=166 mg., given by mouth 1/2 hour after inoculation and repeated daily.

6 mice inoculated and treated for 5 days. All alive and well 9 weeks later.

Controls:

6 mice inoculated and not treated. All dead within 60 hours and organism recovered from heart blood and peritoneal fluid.
6 mice treated for 5 days but not inoculated. All alive and well 9 weeks later.

(ii) *Urinary Carriers*

Immature Dutch rabbits were used and the carrier condition induced by Coplans's (1940) method.

B. typhosus:

7 carriers. Treatment started on 19th day Sulphonamide E.O.S. 2 grammes per kilogramme by mouth alternate days for 5 doses and then daily for a further 33 doses (to surviving animals). In every case the bladder and urine became free from infection.

6 untreated carriers. 1 recovered spontaneously. In 5 infection persisted in the bladder or urine.

B. paratyphosus A:

5 carriers. Treatment started on 40th day Sulphonamide E.O.S. 2 grammes per kilogramme by mouth daily for 45 doses. In every case the bladder and urine became free from infection.

6 untreated carriers. Infection of bladder and urine persisted in all animals.

Conclusions.—Sulphonamide E.O.S. controls acute infections by *Str. pyogenes* and pneumococcus Type III in mice and chronic infections of the urinary carrier type due to *B. typhosus* and *B. paratyphosus A* respectively in rabbits.

Clinical Observations

The clinical data relating to the toxicity of sulphonamide E.O.S. are derived from 130 cases treated for a variety of acute infections. The doses used in different age groups are given in Table VI.

TABLE VI.—*Sulphonamide E.O.S. Dosage (Clinical Toxicity Test) (130 Cases)*

Group	No.	Average Age in Years	Dosage in Grammes					
			Initial		1st 3 days		Total	
			Range	Average	Range	Average	Range	Average
Infants* (up to 12 months)	27	6.12	1-1	0.8	1-18	10.3	2-67	21.7
Children (1 to 10 years)	31	3.1	1-3	1.5	2-45.1	19.0	5-82.1	36.7
Adolescents (10 to 20 years)	17	16	2-4	2.5	12-49	29.3	12-72	44.6
Adults (above 20 years)	55	—	1-41	2.5	9-56.1	32.0	15-100	51.9

* The youngest infant, aged 3 weeks, was given an initial dose of 1 gramme, 11.1 grammes in three days, and 17.1 grammes in 10 days. When first seen she was extremely ill with bronchopneumonia, and artificial respiration was required. An oxygen tent and *o*-lobeline injections were used. The condition came steadily under control in the course of a few days. No toxic signs attributable to the drug were noted in spite of the exceptionally heavy dosage adopted.

The general malaise of sulphonamide therapy was very little in evidence, and that miserable sequence of pallor, nausea, and vomiting characteristic of sulphapyridine never occurred. In many cases (not included in Table VI) treatment was instituted with sulphapyridine and subsequently completed with sulphonamide E.O.S. The general appearance and subjective feeling of severe illness of these patients disappeared rapidly when the substitution was made. The visible change for the better on E.O.S. therapy was very remarkable indeed.

Cyanosis was commonly seen, but never caused any distress or necessitated the interruption of the prescribed course:

Absent...	40%
Trivial...	28%
Substantial...	29%
Severe...	3%
Requiring withdrawal of drug...	0%

Vomiting was rarely encountered. In pregnancy and meningitis vomiting often occurs without provocation. If such cases are excluded the trouble was confined to a small minority of infants and young children in whom the causal relation between the drug and the vomiting was by no means clear.

Leucopenia.—Routine blood counts were made without bringing to light any instance of agranulocytosis or simple

leucopenia. The leucocytes were never fewer than 6,000 per c.mm. of peripheral blood, with the exception of one case in which the white count fell to 5,400 cells per c.mm.

Anaemia.—Minor degrees of anaemia were found, but not with greater frequency or of greater severity than is usual after severe infective illnesses. No severe anaemia of aplastic or of haemolytic type was ever observed.

Rashes.—One patient developed a simple erythematous rash—a fine pink widely distributed eruption occurring in a young child after a week of treatment with E.O.S.

A curious case of acidosis (Case 25, Table VII) occurred in a young woman of 28 who was semicomatose from meningococcal meningitis. There were no ketone bodies in the urine, but the alkaline reserve of the blood was low. In terms of CO₂ binding power it varied between 34.8 vols. CO₂% and 36 vols. CO₂% respectively over two successive days (normal value, 53 to 77). The inorganic blood phosphorus remained within normal limits. The pH of the urine fell to 5.0 (analyses by Dr. S. J. Hopkins). The outstanding clinical feature was pronounced hyperventilation beginning at the end of the second day of treatment, by which time 40 grammes of sulphonamide E.O.S. had been taken. It persisted for three days, and was unaffected by oxygen administration (B.L.B. mask). There was no cyanosis. Hyperventilation subsided when full doses of alkalis were given. Administration of E.O.S. continued uninterrupted, and its curative effect as judged by the mental condition, defervescence, and observations in the cerebrospinal fluid was not prejudiced. The temperature was normal within 7 days.

Although the case must be put on record it is by no means certain that the abnormality was caused by the drug, and the complication might possibly have been prevented by a freer use of routine alkalis, always advisable for febrile patients taking sulphonamides.

The general inference to be drawn from these observations is very satisfactory indeed. In spite of the heavy doses given and the cyanosis produced, there were no serious complications, and the assortment of symptoms which distress without endangering the patient when sulphapyridine is used were conspicuously absent.

Chemotherapeutic Effect (Human)

The drug has now been used in a large number of different clinical conditions with apparently excellent effect—e.g., acute *B. coli* infections of the urinary tract, purulent infection, septic cuts, acute infections of ear, nose, and throat, pneumonia (including pneumococcal and Friedländer infections, the mixed bronchopneumonias of infancy), and septic pleuritic effusions. The expected recovery rate in these disorders is reasonably high even when non-specific therapy alone is carried out. The prognosis varies greatly from case to case. For these reasons it is extremely difficult to secure a datum line from which to judge the success or failure of any new curative method. More trustworthy conclusions can be formed by selecting more intractable

TABLE VII.—*Dosage of Sulphonamide E.O.S. (Acute Cerebrospinal Meningitis—Meningococcal)*

	Adults (Grammes)	Children (Grammes)			
		10 years	5 years	2 years	Infants

diseases, such as chronic *B. coli* infections of the kidney and bladder or purulent meningitis, as the medium for therapeutic assay.

Attention has therefore been centred on acute epidemic cerebrospinal meningitis. The cases all occurred in the

Guy's Hospital Sector of the E.M.S. during 1940 and the early part of 1941. These patients were suffering from the disease in its acute form and many were very seriously ill indeed. Their ages ranged from 7 months to 63 years. About one-quarter were either less than 1 year or more than 45, and so fell into the age periods of gravest prognosis. The general dosage scheme is given in Table VII. Small variations were introduced to meet the needs of individual cases. The amount of sulphonamide used was not so great as these figures suggest. It must be remembered that 1 gramme of sulphonamide E.O.S. is equivalent chemically to no more than 0.57 gramme of sulphanilamide.

The outstanding clinical features of the cases are indicated in Table VIII. In every instance Gram-negative diplococci were seen in the cerebrospinal fluid. In most cases the organism grew in culture and many of them were typed. The commonest type was Group I, but some were not agglutinated either by Group I or Group II serum.

Case 19 is of particular interest. It demonstrates the efficacy of sulphonamide E.O.S. when administered by rectum. It also indicates that pregnancy does not interfere with the action of the drug and is not affected adversely by it. Normal labour occurred later at full term and the child was correctly formed and well nourished. The mother's health during the later months of pregnancy was excellent and the puerperium passed uneventfully. A considerable number of patients were comatose or semi-comatose on admission. In spite of the high proportion of infants and elderly persons and the coincident pulmonary diseases of Cases 2, 24, 26, and 34, the mortality rate of 9% is reasonably low. Analysis of the factors leading to death in the three fatal cases reveals special features in each case.

Case 1.—This was a neglected case, and chemotherapeutic treatment was not instituted until the third week of illness, when hydrocephalus was already established.

TABLE VIII

Case No.	Age Years	Treatment Day of illness	C.S.F. (1st Lumbar Puncture)			Comment	Result
			Pressure mm.	Cells (Polymorphs per c.mm.)	Protein Per cent.		
1	7/12	20th				A neglected case in coma with hydrocephalus already established	Died in 48 hours
2	10/12	2nd	300	520	0.24	Intensely ill and unconscious. Had only recovered from pneumonia a month previously	Complete recovery 2½ weeks
3	11/12	14th	+	3,140	0.24	Slow onset. Convulsions just before admission	Complete recovery. Temp. normal in 4 days
4	1 3/12	3rd	+	9,000	0.30	Very severe case. Pneumonia present on admission	Complete recovery. Rapidly controlled, but tardy clearance
5	1 9/12	3rd	+	3,460	0.90	Full average severity. Semi-comatose	Complete recovery
6	1 10/12	3rd	300	1,840	0.10	Average severity	Inadequate initial dosage, recovery protracted but eventually complete
7	1 11/12	2nd	280	4,250	0.45	" "	Complete recovery
8	3	2nd	250	2,140	0.16	" "	" "
9	5	4th	320	7,360	0.10	" "	" "
10	7	5th	290	2,000	0.65	" "	" "
11	7	5th	250	1,620	0.20	Semi-comatose. Old mitral regurgitation. Profuse herpes	" "
12	9	4th	280	3,290	0.38	Average severity	" "
13	13	3rd	230	1,106	0.35	Abrupt onset. Delirium. Screaming. Semi-coma	" "
14	14	2nd	260	4,380	0.29	Average severity	Complete recovery. Temp. normal in 3 days
15	16	5th	300	12,700	0.30	Full average severity	Complete recovery
16	17	4th	290	7,200	0.25	Average severity	Complete recovery. Temp. normal in 5 days
17	19	4th	240	800	0.20	Full average severity	Complete recovery
18	20	1st	335	2,720	0.36	Semicoma. Petechial rash	Complete recovery. Five mths. later gave birth to healthy full-term child
19	22	2nd	250	2,600	0.35	Pregnant, and comatose 5 days. Early medication entirely per rectum. 87 grammes administered in this way over period of 5½ days before patient able to take by mouth. Subsequent progress exceptionally rapid	
20	24	3rd	200	2,280	0.22	Average severity	Complete recovery. Temp. normal in 41 days
21	24	3rd	210	3,490	0.31	" "	Complete recovery. Temp. normal in 3 days
22	26	4th	300	10,000	0.50	Insidious onset. Delirious on admission but not comatose	Complete recovery
23	27	3rd	280	8,620	0.37	Full average severity	Died on 4th day of treatment.
24	28	2nd	320	19,000	0.56	Very severe case. Coma complete within 24 hours. Fat and difficult to nurse. Vomiting conspicuous. Fluids, food, and drugs by nasal tube	P.M.: meningitis clearing. Cause of death, purulent bronchitis
25	28	3rd	315	28,000	0.52	Very severe, with persistent coma. Hyperventilation and acidosis for several days. Severe facial herpes	Complete recovery. Control established steadily. Temp. normal in 6 days
26	34	6th	324	9,800	0.15	Average severity. Old fibroid phthisis with cavities (X-ray finding)	Complete recovery. Temp. normal in 2½ days
27	35	3rd	280	10,100	0.28	Severe illness. Semicomatoze for 2 days, but able to take fluids by mouth	Complete recovery
28	35	2nd	240	7,420	0.10	Average severity	Complete recovery. Terminated by crisis in 36 hours
29	40	4th	350	13,000	0.48	Very severe. Semicoma for several days. Blood transfusion on 5th day of treatment. Temperature normal 36 hours later	Complete recovery
30	46	3rd	320	11,900	0.30	Severe illness; delirium but no coma	Died after 2 days' treatment.
31	48	3rd	140+ (Pus too thick to register correctly)	16,000 rising to 84,000	1.50	Intensely ill, comatose, dyspnoeic, cyanosed, and finally hyperpyrexial. Drug administered by rectum	P.M.: suppurative meningitis and acute suppurative pericarditis. Section of heart examined for secondary invaders, but none seen
32	53	4th	210	5,600	0.27	Average severity. Acute monarthrititis of rt. wrist, a complication on 2nd day of treatment, continued for a little time after subsidence of fever and cerebral symptoms	Complete recovery
33	56	5th	250	6,200	0.18	Average severity	" "
34	63	2nd	300	9,000	0.90	Severe attack. Semicoma, but able to take fluids by mouth. Acute bronchitis on admission. Bronchopneumonia as a complication after 2 days' treatment, but temp. normal a week later	" "

Case 24.—This patient appears to have died of a complication of the unconscious state, possibly due to inhalation of infected material, rather than from the meningitis itself.

Case 31 acquired a particularly lethal and rare complication—suppurative pericarditis.

There were no deaths among those who were seen during the first week of illness and who remained free from serious secondary infections of the viscera. For these reasons more than for the simple statistical fact of a low mortality rate on a limited series of cases, I feel justified in believing that sulphonamide E.O.S. has a pronounced curative action in this disease. Very diverse figures have been published by other observers using different remedial agents. This diversity is readily understood by anyone who has worked among these patients. The mortality rate is affected greatly by so many factors other than that of the chemotherapeutic potency of the drug employed. It varies with the epidemic, locality, age distribution, the speed with which the diagnosis is made, the amount of medical attention which can be focused on each patient, and, above all, with the perfection of the nursing care available. Superb nursing skill is required by delirious, comatose, or semiconscious patients. I know that I have been particularly fortunate in my house-physicians and nurses.

The figures given below furnish a suitable basis for comparison.

Epidemic 1914-17 (pre-sulphonamide):
5,306 cases; mortality 65%

These national figures were analysed by H. D. Rolleston (1919), who found in them evidence of a dwindling mortality as serum treatment came into more general use.

Present epidemic, first quarter, 1940 (sulphonamides widely used):
4,388 civilian cases; mortality 23.7%

Individual groups of smaller numbers but more unified medical control have yielded better results:

120 cases observed personally by Banks (1940) (sulphapyridine or other sulphonamides used in all cases):
Mortality 10%

154 cases at Wrexham (*Lancet*, 1940) (various doctors) (sulphonamides widely used):
Mortality 12.3%

The mortality in the present series treated with sulphonamide E.O.S.—34 cases (9%)—is therefore closely in accord with the current figures.

Summary

A new sulphonamide of low toxicity and full chemotherapeutic activity in acute cerebrospinal meningitis is described. Less critical clinical data lead one to expect that it will be equally effective in combating infections due to *B. coli* and haemolytic streptococci. More extended clinical observations will probably reveal other fields of utility. In animals it controls acute infections due to *Str. pyogenes* and pneumococcus Type III, and chronic urinary infection by *B. typhosus* and *B. paratyphosus* A. Its low toxicity has been investigated by experiment on mice. The rarity with which in therapeutic dosage it provokes unpleasant side-effects in man has been demonstrated by a clinical survey of 130 cases. It seldom causes vomiting, and malaise attributable to the drug is inconspicuous. It is hydrolysed in the body with the liberation of sulphaniilamide *in situ*, and is excreted in forms which are far more soluble than those following the administration of sulphapyridine or sulphathiazole. It possesses the convenient property of ready solubility in water. Neutral and almost tasteless pharmaceutical solutions can easily be prepared for administration by mouth, rectum, or vein.

THE SIZE AND VISIBILITY OF THE FILTERABLE OR VIRUS BODIES

BY

ALFRED C. COLES, M.D., D.Sc.
M.R.C.P.Lond., F.R.S.Ed.

Consulting Physician to the Royal Victoria Hospital and Royal National Sanatorium, Bournemouth

The filterable, so-called ultra-microscopic or elementary, bodies, generally spoken of as the viruses, are not easy to examine on account of their very small size and the difficulty of staining them; but fortunately they are nearly always present in enormous numbers, often in almost pure cultures. The measurement of such small bodies is very difficult by eye-piece or screw micrometer, and usually one has to resort to photography.

The Photographic Method of Measurement

Muir and Ritchie (1937) state:

"In the microscopical study of virus particles Barnard has utilized photography by ultra-violet light, which is of shorter wave-length than that of the visible rays, and thus has obtained greater microscopical resolution. By this method he has been able to demonstrate photographically virus particles of 0.075 μ in diameter."

Let us compare this with the results obtainable by the use of the ordinary microscope and objectives in common use when these are employed correctly. The late Mr. Edward Milles Nelson (1909), who devoted the whole of his long life to the microscope and was undoubtedly the greatest authority on the subject, says: "Briefly, the method is to bring the object just to the point of invisibility by reducing the N.A. (numerical aperture), and then the correction for antipoint will be the measure of the object." I might add that one can determine the minimum visible of any objective by the following calculation: for white light of 45,300 waves per inch divide 1.041 by the N.A.; for green light of 50,000 waves per inch divide 0.942 by the N.A. of the objective. A full table of the values of the N.A. is given in Mr. Nelson's paper.

I have used this method of measuring by extinction for many years, employing for this purpose a Leitz 1/10⁴ fluorite objective fitted with an iris diaphragm graduated in N.A.s, immediately behind the back lens, and find it remarkably accurate and easy after one has had some practice.

From Nelson's table it will be seen that an objective of N.A. 1.4 will reveal a particle of 0.0744 μ with white light and 0.0673 μ with a green screen. Nelson later, in 1935, informed me that even greater visibility could be obtained by using a motor head-light bulb (3 amps 12 volts with a transformer, as suggested by Ivimey-Cook), with the filament in focus, and a deep blue screen. Then the size of an object seen would be 0.841 divided by the N.A.; so that an objective of N.A. 1.3 would show a particle 0.065 μ , and one of N.A. 1.4 a particle 0.06 μ , in diameter. From these figures, given in much greater detail in a previous paper (Coles, 1929), ultra-violet microscopy does not seem very urgently needed.

Mr. Eliot Merlin (1929), the distinguished microscopist, in concluding his masterly article, says:

"In the writer's opinion it is of paramount importance that the true optical capacity of the ordinary worker's microscope, furnished with ordinary glass and fluorite achromatic or apochromatic object-glasses, should be clearly understood and not underestimated, this being the tool exclusively used by thousands of laboratory and technical workers all the world over. It cannot be too emphatically maintained that it is an experimentally absolute fact that an object-glass of 0.4 N.A. (i.e., a common

1/2-inch) will, in white light of wave-length of 45,300 per inch, just render visible a particle of 0.262μ in diameter; and similarly the 1/12 oil immersion of 1.30 N.A. in common laboratory use should, if properly used to its full defining capacity, reveal particles of not less than 0.08μ diameter in white light, of 0.0724μ diameter with a screen wave-length of 50,000 per inch, and of 0.057μ with the photographic wave-length of 63,500 per inch."

Stained Films and Filtration Method Compared

In recent times organic membranes such as collodion have been devised by Elford (1931) to test filterability. These are called "gradocol" membrane, and by their means Elford and his co-workers have computed the size of the particles. A list of filterable viruses, with their size, is given by Mackie and McCartney (1938). The unit used to express these minute viruses is $m\mu$ —i.e., one-thousandth part of a micron (μ) or one-millionth part of a millimetre.

When we compare the size of the filterable viruses as determined by microscopical methods on stained films we are at once struck with the extraordinary difference between these and those obtained by filtration methods. The following measurements of the elementary bodies of definite virus diseases will show how much the results differ.

The size of the virus of *variola* and of *vaccinia* as determined by filtration is stated to be 0.15 to 0.175μ . They were not recognized as the causal organisms till Paschen described them in 1906, but as a matter of fact Dr. John Buist of Edinburgh had fully described and photographed them nearly twenty years previously. Buist (1887), after staining them with aniline gentian violet, gave their size as from 0.15 to 0.5μ ; and von Prowazek (1912) gives exactly the same figures. Mr. Nelson and Mr. Eliot Merlin, knowing nothing of these figures, estimated the size of some of them as up to 0.45μ in preparations stained with Giemsa which I sent them in 1922. *Vaccinia* was the first of the filterable bodies that I dealt with in my work on the viruses in 1913.

The size of the virus of *foot-and-mouth disease* is given as 0.01 to 0.02μ , or 10 to $20 m\mu$, and it is regarded as one of the smallest of filterable bodies and quite invisible.

In 1929 Sir Charles Martin, then director of the Lister Institute, kindly sent me films from the vesicles of cases of foot-and-mouth disease, and later sealed ampoules of the filtrate; and in 1933 Dr. (since Sir) John Ledingham, his successor, sent some of the filtrate—both through the kind service of Dr. J. T. Edwards. Films made from the filtrate were fixed in alcohol and stained for twenty-four to forty-eight hours in well-diluted Giemsa. Films were also made with indian ink as in Burri's method, and control films of the ink alone were made at the same time. Lastly, the filtrate was spread in thin film on perfectly clean slides and merely allowed to dry in the air. When these were quite dry they were put under a cover-glass and the margins sealed with cement, taking great care that none of the cement should run in—i.e., they were mounted, unfixed, and unstained in air. It is interesting to note that these preparations and the indian-ink films mounted in 1929 and 1933 are to-day in as good condition as when they were made.

The Giemsa-stained films, when examined with the 1/10-inch oil-immersion objective, show clearly innumerable very fine virus bodies, differing from those seen in other virus diseases, such as *vaccinia*, herpes, molluscum, etc., on which I have been working for the last twenty-eight years, only by their enormous number and their small size. These stained preparations, when examined by dry dark-ground with only the 8-mm. or 1/3-inch apo-objective and an 18 compensating ocular, show the minute bodies exceedingly well. The indian-ink preparations under the oil-

immersion objective reveal the elementary bodies very distinctly, in marked contrast to the control film of ink. The merely air-dried unstained films mounted in air, when examined by dry dark-ground illumination with the same objective, distinctly show the minute bodies, and exclude the possibility of their being colloidal protein molecules or precipitates from the stain.

Mr. Eliot Merlin, who has during the past years examined nearly all my preparations of virus bodies of various diseases, writing in 1929, confirms my findings in every way. He describes the preparations of foot-and-mouth disease as consisting of densely packed strongly stained particles, measuring from 0.15 to 0.3μ in the stained films, and precisely similar bodies were seen in the indian-ink slides. He says:

"Your findings re size and appearance are in agreement with the facts as they appear to me, and the presence of the bodies in the unstained, merely air-dried, films is pretty conclusive that what we had seen in the stained films was not due to stain debris. The foot-and-mouth virus seems to me to greatly resemble the vaccine and many other virus bodies which we have examined previously. What surprises me is that the bodies with which the films swarm should be considered difficult to define with the ordinary microscope. I think the appearance of the bodies under the microscope is in itself fairly convincing to anyone with an open mind on the subject. If they be not virus bodies one wonders how they can be proved not to be."

Causal Virus of Various Diseases

The causal virus of *yellow fever* is said to be one of the smallest of the elementary bodies, and according to filtration experiments is estimated to measure 0.018 to 0.027μ , or 18 to $27 m\mu$. Blood films from monkeys infected with yellow fever were kindly sent me by Prof. Edward Hindle in 1929 and Prof. W. Schüffner in 1931, and when these were stained with Giemsa I found minute bodies in the red blood corpuscles and also free in the plasma. They varied considerably in size; many measured from 0.1 to 0.35μ , but some were only just visible specks. The larger bodies were resolvable in most cases into three or four minute spots not larger than 0.1μ . The number seen varied according to the day of the disease; they were most numerous on the second or third day of the fever, and in several of the films many free and intracorpuseular forms could be seen in every field.

In blood films of patients naturally affected and in volunteers inoculated with about 0.33 c.cm. of dried serum of infected blood from cases of *dengue fever*, somewhat similar bodies were found. These were numerous on the first three days of fever, considerably less numerous on the fourth day, and on the fifth and sixth days they were exceedingly few, being found only with difficulty. Blood films from three cases of *sandfly* or *pappataci fever* taken during the first twenty-four hours showed bodies almost exactly like those of *dengue*. Mr. Merlin kindly examined and confirmed my findings in these three virus diseases, which have been described in detail with photomicrographs elsewhere (Coles, 1937).

Lastly, let us examine another of the extremely small virus bodies, that of *poliomyelitis*, which measures according to filtration experiments 0.008 to 0.017μ , and according to other textbooks from 0.010 to 0.020μ . I have received air-dried films from proved infective filtrate of poliomyelitic monkey-cord suspension from three reliable sources—namely, Dr. J. A. Kolmer, Dr. A. B. Sabine, and Dr. E. W. Schultz, all of the U.S.A.—and after staining these in Giemsa very definite elementary bodies were easily seen. They varied in size from 0.15 to an average of 0.2 to 0.3μ . These have been described and photographed (Coles, 1939).

Discussion

How can the marked difference in size of the elementary bodies as determined by filtration experiments and microscopical methods be explained? It should be remembered that the size of the virus particles as measured by means of collodion filters represents the size of the *smallest* of the living bodies and not that of the average of the stained elementary bodies. Have fixation and staining any effect on the size of the particles? The answer to this is strikingly in the affirmative, and to a much greater extent than most of us realize. In 1929 I stained a film containing *Treponema pallidum* in Giemsa for fifteen to twenty minutes, and after washing and drying examined it with the 8-mm. or 1/3-inch apo-objective by dry dark-ground illumination, without any cover-glass or mounting medium. A spirochaete was very easily found by this means, partly because the eosin red of the Giemsa shows up brilliantly by dark-ground illumination, but chiefly because the difference in its refractive index and that of air is so great. The position of the spirochaete was logged, and ringed with the marker. The oil-immersion objective was then turned on, and the spirochaete was practically invisible; only after prolonged careful search was it seen, and it appeared as the very thinnest and finest spirochaete possible. The slide was placed back in the stain for twenty-four hours, and then it was markedly thicker and very easily seen with the oil objective. A film or a section stained by any of the flagella stains after mordanting, or in silver-impregnated preparations, shows spirochaetes and leptospira as very thick coarse structures, easily seen with quite low-powered objectives.

As the virus bodies are probably very minute organisms, why should the difficulty of examining them be further increased by restricting the examination to them in the living condition? Do we examine sputum for tubercle bacilli, or the diphtheritic membrane or its cultures for the bacilli, in the living unstained preparations? The size of all bacteria is determined in stained preparations, and in the case of the tubercle bacillus in films mordanted by carbolic acid and heat. The size of the tubercle bacillus is generally given as varying from 2.5 to 3.5 μ in length and 0.3 μ in thickness: has anyone detected this bacillus in its unstained living condition, and can anyone even guess at its size in its living state?

The only reason I can imagine why the elementary bodies are studied in their living unstained state is that the very few exponents of ultra-microscopy would have us believe that this is the only correct method: even if this method were adopted the viruses would never be seen but could only be photographed.

Conclusions

I am of the considered opinion (a) that all the filterable virus bodies, including the smallest and the so-called invisible virus of foot-and-mouth disease and that of infantile paralysis, are easily within the range of the ordinary microscope when used correctly; (b) that ultra-microscopical methods are not essential, and their use has so far added little to our knowledge.

CLINICAL MANIFESTATIONS OF TETRYL AND TRINITROTOLUENE

BY

J. HILTON, M.B., Ch.B.

AND

C. N. SWANSTON, M.R.C.S., L.R.C.P.

Medical Officers to a Royal Ordnance Factory

Since many filling factories have been built recently in different parts of the country it might be of interest to practitioners to know something about the effects on the human body of continued exposure to tetryl and trinitrotoluene.

Tetryl, or "C.E."

This compound is a sharp crystalline powder, yellow in colour. Its clinical manifestations are as follows:

1. The powder stains the skin of the hands, face, neck, and also the hair, and this colour deepens to orange on exposure to sunlight. It should be emphasized that the staining varies considerably in different workers and bears no relation whatever to any of the following manifestations.

2. New workers sometimes complain of a sharp tingling sensation in the nose. This causes sneezing and more rarely epistaxis, and is due to the irritating effect of the crystals on the nasal mucous membrane.

3. The commonest complaint from tetryl workers is dermatitis. This starts as an erythema, followed by a papular eruption accompanied by some exfoliation. It arises in the region of the sweat glands of the face—i.e., the naso-labial fold and submandibular regions of the neck. It may spread all over the face, causing severe irritation, and in some cases gross oedema of the eyelids, which may prevent the patient opening the eyes for two or three days. In severe cases secondary sensitization may occur on the hands, arms, and trunk. Should tetryl come into contact with the conjunctivae a mild conjunctivitis results. Constitutional symptoms are present only in the more severe cases, usually as headaches and general malaise. They are to some extent understandable, as patients suffering from extensive rash often lose sleep. The treatment of C.E. dermatitis is first and foremost removal from contact with the powder. It is not enough merely to change the worker's occupation: he or she must be removed right away from the vicinity of the powder, otherwise the condition will be aggravated by the small amount of dust present in the atmosphere in all shops where tetryl processes are carried on. It is also important that the worker be given a complete change of working clothes. The local treatment, generally successful, consists in frequent applications of calamine lotion or, if there is much desquamation and drying of the skin, lotio calaminæ oleosum. A word of warning is, however, necessary when using the latter preparation: tetryl workers should be told on no account to use oily preparations on their skin as a preventive measure, as by so doing ideal conditions are produced for the development of a second attack of C.E. dermatitis. Mild cases clear up in a few days, but severe rashes often persist for two or three weeks. Suspension from work is seldom necessary. When the dermatitis has quite cleared up the worker may return to contact work, but if a second or third attack occurs it is an indication that the patient is very susceptible and should be removed permanently from tetryl work. In our experience those workers who develop oedema of the face and periorbital tissues are bad risks, and we remove them permanently from contact at the first outbreak of the rash.

4. Although it is not generally admitted that tetryl gives rise to any constitutional symptoms, we have found that numbers of new workers complain of epigastric pain, with nausea or vomiting. These symptoms, like those of T.N.T. toxic gastritis, bear no relation to food and are seldom severe enough to keep the patients away from work. Such workers are removed from contact until the symptoms abate. They are then allowed to return, and usually no further trouble arises.

Trinitrotoluene, or T.N.T.

T.N.T. is a yellowish crystalline powder more stable than C.E. and is used either by itself or mixed with other sub-

stances—e.g., ammonium nitrate (amatol), barium nitrate (baratol). It is a highly toxic substance, of which the clinical manifestations are as follows:

1. The hands and, more rarely, the face and the hair are stained orange, but the staining is not so deep as with C.E. This staining should not be confused with the yellowish coloration due to jaundice.

2. *Dermatitis*.—This arises on those skin surfaces which are exposed to direct contact with the explosive—i.e., hands, forearms, neck, wrists, and ankles, the last three areas through friction from the operator's clothing. It seldom appears on the face, but this may be involved in a general outbreak all over the body. On the hands it starts as a sago-grain eruption, and is particularly evident between the fingers and on the thenar eminence. Elsewhere it takes the form of a coalescing papular eruption with areas of erythema. Desquamation is the rule, and may be severe, leading to complete exfoliation of the hands and feet. Small "powder"-holes are also seen. The irritation is intense; and treatment is the same as for C.E. dermatitis—i.e., removal from contact and local application of bland lotions and ointments. One attack of T.N.T. dermatitis, unless unusually severe, is no bar to further employment with the explosive.

3. *Cyanosis*.—T.N.T. exerts a specific action on the haemoglobin, forming a mixture of methaemoglobin and NO-haemoglobin. A large percentage of these workers are "cyanosed" to a greater or lesser degree and present a typical appearance. The lips, tongue, and mucous membranes become a greyish-mauve shade, very different from the true cyanosis of cardiac or lung disease. There is no real anaemia, and very often the condition is symptomless. In fact, we have met workers looking quite purple who declare that they have never felt better in their lives. When present the symptoms are those of oxygen dearth—i.e., fatigue, lassitude, and dyspnoea on exertion. At one time it was our practice to remove from T.N.T. contact all workers showing this sign no matter to what degree, but now we allow mild cases, in which the patients are otherwise well, to remain in contact under observation.

4. *Toxic Gastritis*.—This is a definite syndrome, and is not to be confused with other forms of gastritis arising in T.N.T. workers, including latent hypochlorhydria, which may be unmasked by the action of the trinitrotoluene. The symptoms are: (1) central epigastric pain of a colicky nature, relieved by rest but not by vomiting, and bearing no relation to food; (2) nausea with or without vomiting; (3) a feeling of tightness in the chest; (4) anorexia; and (5) constipation. The cardinal symptom is pain. These patients present a distinct appearance. Cyanosis may or may not be present, but they show a greyness of the face, with a worried expression, and often a definite pallor over the bridge of the nose extending on to the cheeks; the tongue is usually clean. Examination of the abdomen reveals nothing except slight epigastric tenderness, probably due to the constant retching and vomiting. The treatment again is immediate removal from all contact, including the changing of any contaminated clothing and a thorough cleansing of the skin. In very early cases the patient need not be suspended from work, but if there is much vomiting—in our opinion the most important symptom—rest in bed is indicated, combined with saline purges and a high carbohydrate diet containing plenty of fresh fruit and vegetables. There is some evidence to show that vitamin C in large doses may be of value in these cases. Workers who have had a severe attack of toxic gastritis should not be allowed to return to T.N.T. work.

5. *Toxic Jaundice*.—Fortunately this is a rare complication, but it carries a 30% mortality, and all such cases must be treated as serious. It may be heralded by an attack of cyanosis or toxic gastritis, or it may arise *de novo*, patients being found who are symptomless and maintain that they feel perfectly well. The jaundice starts in the conjunctivae and spreads rapidly to the skin. It is a late and grave sign, and indicates severe liver damage. These patients should always be removed to hospital, as it is impossible to carry out adequate treatment at home. The treatment is the same as that for toxic jaundice due to other causes. On admission to hospital the patient should be given a warm bath, and if possible the skin should be scrubbed with acetone or ether to remove any trace of T.N.T. that may still be present.

Special attention should be paid to the hands, nails, and hair. Cyanosis may be treated with inhalation of oxygen and carbon dioxide, but this is only necessary where there are definite symptoms of oxygen dearth. The bowels should be kept open by saline purges, and the diet should contain fresh fruit and vegetables, and be rich in carbohydrate, calcium, and vitamin C. It has been maintained that Webster's urinary test for T.N.T. is invariably negative in cases of toxic jaundice, but we are of the opinion that this is not so. We have obtained a positive reaction in a severe case six weeks after admission to hospital. Prognosis on these cases is difficult and should be given with great caution until the patient is well on the way to recovery and the jaundice has cleared up. It is often months before they are fit to return to work, and on no account should any patient ever be allowed back on T.N.T.

6. *Aplastic Anaemia*.—This is a still rarer complication, nearly always fatal and sometimes preceded by jaundice. We have seen three cases, all of them fatal, but in only one was there a definite history of jaundice.

Conclusion

These manifestations appear formidable on paper, but the percentage of workers in contact who are affected is small. Our experience points to the fact that, other things being equal, personal idiosyncrasy must play an important part in the production of toxic symptoms. We are sure that factory medical officers as a body would willingly co-operate with general practitioners in helping to diagnose these somewhat unusual conditions.

Medical Memoranda

Preliminary Note on the Properties of s-Methyl Isothiourea Sulphate

While working with some thiourea derivatives it was observed that s-methyl isothiourea sulphate when administered intravenously in animals raised blood pressure and stimulated respiration. Further observations showed that it also acts when given by mouth. The pharmacological properties of the substance have apparently not been described hitherto, and are manifest in doses which after repeated trials appear to be harmless in lower animals and in man. The circulatory effects have been observed in the dog, cat, rabbit, and man. The rise of blood pressure is either mainly or entirely of peripheral origin, since it takes place after destruction of the central nervous system. The blood-pressure increase is not likely to be the result of stimulation of sympathetic-nerve endings, as it occurs when these endings are paralysed by ergotoxine.

Other smooth muscle besides that of the blood vessels is contracted by s-methyl isothiourea sulphate, notably plain muscle of the isolated intestine. In the whole animal, however, this action on the intestine is not a prominent feature except with big doses. A more detailed communication describing the action in animals will be published shortly, in collaboration with Dr. M. McGeorge (Dunedin) and Prof. Mahomed Sherif (Cairo).

Following animal investigations it was decided to study the action in man. The work in this connexion began in collaboration with Dr. Nassif in Cairo and has been continued by me. It has been shown in healthy men that doses of 0.2 to 0.4 gramme of s-methyl isothiourea sulphate when taken orally cause slowing of the heart and usually a blood-pressure rise. No subjective sensations have been observed to accompany these changes. Two doses of 0.4 gramme given with an interval of about thirty minutes between them have been administered on a number of occasions without leading to subjective sensations. The fall in heart rate is then as much as 20 beats per minute, and in some instances the heart rate has dropped to below 50. On several occasions healthy volunteers carried out a standard Army exercise-tolerance test before and after administration of

s-methyl isothiurea sulphate and observed no special difference as a consequence of taking the substance.

ITS POSSIBLE VALUE IN CASES OF SHOCK

Some observations have been made by me in man and in experimental animals to ascertain if this substance might be of value in the treatment of surgical shock. It has been noted in about twenty obviously moribund patients, mostly medical cases with terminal circulatory collapse, that the systolic blood pressure may rise promptly from, say, 60 to 120 mm. after the intravenous administration of 0.2 to 0.4 gramme. The diastolic pressure is raised proportionally. The blood pressure remains elevated for fifteen minutes to one hour. The heart rate, however, may fail to slow or does not diminish to the degree observed in health. Some of these results were encouraging in that several moribund patients made a temporary recovery. Two cases of severe surgical shock were treated by the intravenous injection of s-methyl isothiurea sulphate. Both patients survived, and improvement coincided with the administration of the substance. It is regretted that most of the clinical observations were not made on cases of surgical shock, but opportunities for a satisfactory study of this subject are lacking in New Zealand.

More definite evidence has been obtained that the substance is of value in treating acute shock produced experimentally in healthy animals. Thus crushing of limbs and extensive abdominal injuries were employed in anaesthetized cats and dogs to reduce the level of the blood pressure to 30 or even 20 mm. Hg. Ordinarily when the blood pressure has been reduced to such levels cessation of the heart beat usually follows within a minute or two. A majority of animals with blood pressures of 20 or 30 mm. Hg were revived for periods of one or more hours when treated with s-methyl isothiurea sulphate intravenously. It seems, therefore, that the substance delays death if given to animals in extreme traumatic shock. There is thus a chance that the substance would be useful to tide over air-raid casualties which cannot be removed to a place with facilities for transfusion.

The substance also may be worthy of clinical trial in those cases of traumatic shock in which a vasoconstrictor substance could be of value, but even so it should be regarded as an adjuvant and not as an alternative to methods of treatment which restore the blood volume. Patients whose blood pressures remain at a low level despite restoration of the blood volume might be benefited by s-methyl isothiurea sulphate.

In my patients dosage has been controlled by observing the pulse and blood pressure. It appears that in divided doses as much as 1 to 1.5 grammes may be administered in the course of three hours, and probably more would be tolerated. Solutions have been sterilized by tyndallization and kept in ampoules, 0.2 gramme in 2 c.cm. So far only one contraindication to the use of this substance has been found—namely, that it should not be employed in congestive heart failure.

F. H. SMYRK, M.D., F.R.C.P.

Professor of Medicine, University of New Zealand, Dunedin.

Malachite in the Control of Bilharzia

The possibility of controlling bilharzia in Southern Rhodesia has been under investigation for the past two years. This work was begun at the instigation of the medical director of Southern Rhodesia, Dr. A. P. Martin, with the aid of a grant from the trustees of the State Lottery. I proceeded to the colony in the first place in company with Sir Malcolm Watson, director of the Ross Institute of Tropical Hygiene. Certain results of this work seem to be important enough to merit immediate announcement.

An essential phase of the investigation has been a search for effective and practical means of destroying the intermediary hosts of human bilharzia—namely, the snails *Physopsis globosa* and *Biomphalaria pfeifferi*. Previous attempts to destroy these dangerous snails have centred largely around the use of copper sulphate. The principal objections to the use of this substance are its relative toxicity to man and other mammals, its great solubility (approximately ten parts of copper per hundred), and its high cost. Copper carbonate is at least as lethal to snails as is copper sulphate, it is much less soluble than the sulphate (approximately one part of copper per million), and in saturated

solution it has been proved by experiment in Southern Rhodesia to be non-toxic to white rats when given in repeated doses. The relatively high cost of copper carbonate as well as of the sulphate has led to a search for some less expensive form that would be suitable for control work on a large scale.

Malachite (mineralized basic copper carbonate) when ground fine enough to pass through a 200-mesh sieve has been found to be suitable for this purpose. In this condition malachite from two sources in Southern Rhodesia has been proved to be effective in destroying snails both in the laboratory and in actual bilharzial pools in the field. The present cost of malachite in many parts of Africa is less than £1 a ton. Finely powdered malachite yields an effective concentration (dissolved and colloidal) of 0.5 part of copper per million when placed in natural water (from the Macabuzi River, near Salisbury, S.R.). It has been found that the solubility of this substance is considerably increased by mixing it with fresh brewer's waste (i.e., fermented barley) or with the decaying pods of a common Rhodesian tree, *Swartzia madagascariensis*.

These methods of destroying snails will play an important part in a campaign for the control of bilharzia in Southern Rhodesia which will begin shortly. A full account of the control methods to be used is in preparation.

I am grateful to the Medical Director of Southern Rhodesia for permission to publish this note.

Salisbury, Southern Rhodesia

ALAN MOZLEY, D.Sc. Ed.

Melanotic Carcinoma: Sudden Spread after Hysterectomy

The following case may be interesting enough to be worth recording.

CASE REPORT

The patient, aged 41, had hysterectomy performed for fibroids of the uterus on April 25, 1941. Her only complaint was menorrhagia. At operation a routine inspection of the abdominal contents revealed no other abnormality. Pre- and post-operative examination of the chest showed no disease, and the patient left hospital after a normal convalescence. The pathological report on the uterus indicated simple myoma only.

The patient was readmitted on August 1 complaining of abdominal swelling and vomiting for two weeks: for one week she had been breathless. Symptoms had come on quite suddenly twelve weeks after operation. On admission she was cyanosed and breathless at rest; there were scattered subcutaneous black nodules, including three in the abdominal scar; the abdomen was distended with fluid, but a large nodular liver was readily palpated. Search for a primary melanoma revealed only a small scar over the left clavicle. The patient then gave a history that five years ago she had had a "black naevus" there. It was treated with carbon dioxide snow, but increased in size—whereupon it was excised under local anaesthesia. There had been no recurrence since.

She died on August 7. At necropsy melanotic carcinomatous deposits were found in almost every organ of the body—heart, thyroid, lungs, meninges, and brain. The liver weighed 110 oz., and there were profuse deposits in the mesentery, kidneys, spleen, suprarenals, pancreas, and stomach. The abdominal scar was studded with melanotic deposits. The urine gave a positive test for melanogen.

Twelve weeks previously there had been no macroscopical abdominal deposits. If the sudden spread of melanotic deposits was purely coincidental the rapid dissemination after five years' complete quiescence is noteworthy. It is, however, interesting to speculate whether the operation on a distant site initiated the spread: whether, in fact, the malignant cells had lain dormant for five years only to be stirred into activity by the mechanical or physiological disturbance of the operation. Although so far as I know no mechanism for this is described, it seems to be a more possible explanation.

My thanks are due to Mr. Edgar Freshman, under whom the case was admitted, for permission to report it, and to Dr. Norman Ashton, who carried out the necropsy, for the use of his report.

KEEL AND GUNTERY HOSPITAL.

SULPHANILYLGUANIDINE AS INTESTINAL
ANTISEPTIC

In the past various drugs have been used as intestinal antiseptics, mainly without any sufficient evidence that they achieve the effect desired. Not only has any such drug to run the gauntlet of the several digestive secretions and to survive admixture with foodstuffs in successive stages of breakdown, but if it is to act in the lower bowel—and it is here that action is usually desired—it must escape absorption before the intestinal contents reach this area. This is asking much, and, in fact, none of the older intestinal antiseptics possessed all the qualities necessary to overcome these obstacles: those of coal-tar origin were certainly absorbed, because a tolerable daily dose mixed with the daily output of faeces would be actively bactericidal, whereas a corresponding effect was not demonstrable in the stools of patients under treatment. Now that sulphonamide compounds are becoming recognized as having a direct antiseptic action, and are being used more and more in the form of local applications, it is natural that inquiry should be made into the possibility of influencing the intestinal flora by their means. Sulphanilamide itself is much too rapidly absorbed to reach the lower bowel at all, and other less soluble compounds are not believed to reach it in any considerable amount. From a seemingly endless series of these compounds there emerges from time to time one which meets a therapeutic need previously unsatisfied, and although there was no reason for supposing that the peculiar qualities demanded of an intestinal antiseptic could necessarily exist in a compound of this class, such a substance has apparently been found. Sulphanilylguanidine, to which we made a brief editorial reference not long ago, has an action on bacteria comparable to that of its predecessors, but differs from them in being much less readily absorbed, with the result that much of the drug given by the mouth remains in the alimentary tract. This property is the more peculiar because the drug is fairly soluble; failure of absorption, therefore, does not mean that it remains in the bowel largely in a solid and therefore inactive form.

The brief history of this drug is given by D. E. W. Anderson and R. Cruickshank in their paper on page 497 of the present issue. The contribution of these authors to its study is a carefully observed therapeutic trial in bacillary dysentery, for which an extensive outbreak in a mental hospital provided the opportunity. This is a disease in which therapeutic effect cannot easily be assessed in quantitative terms, and the results claimed may seem unimpressive for that reason. It seems nevertheless that a decided amelioration of symptoms, more

particularly in severe cases, was usually brought about within the first two days; that treated patients felt better and regained their appetite at an earlier stage; and that convalescence was shortened. More positive evidence of a specific action was that dysentery bacilli ceased to be recoverable from the stools at an earlier stage in treated than in control cases. Observations on this point were complicated by a change-over from MacConkey's to a more selective medium during the progress of the study; a culture medium which facilitates the detection of small numbers of dysentery bacilli is a valuable asset in such work, and the peculiarly selective action on Flexner dysentery bacilli of the medium described by W. J. Wilson and E. M. McV. Blair on page 501 may be found valuable in further studies of this kind. Anderson and Cruickshank's observations included estimations of sulphanilylguanidine in the blood, urine, and faeces. Blood levels, as claimed in the original American reports, were low, and heavier dosage would therefore probably be safe: it may be added that no toxic effects of any kind were observed in this series except a rash in one patient. Such of the drug as is absorbed is excreted in the urine, where fairly high concentrations are attained, and an adequate fluid intake appears advisable to prevent crystalline deposition in the urinary tract. Varying but mainly high concentrations were found in the faeces, and it was calculated that from one-half to two-thirds of the drug given remained in the bowel.

These authors do not record any general diminution in the numbers of bacteria cultivable from the faeces during treatment with sulphanilylguanidine, but quantitative methods of culture were not employed. Marshall claims that administration to mice causes a striking diminution in the numbers of coliform bacilli in their faeces, and according to W. C. Corwin¹ the effect in dogs and monkeys is not so much a reduction in total numbers of viable bacteria as an increase of Gram-positive cocci at the expense of Gram-negative bacilli. W. M. Firor and A. F. Jonas² found some diminution in faecal coliform bacilli in patients taking the drug, but the effect seems to have been neither consistent nor usually striking. These authors gave the drug for seven days before operations involving resection and anastomosis of the bowel, and obtained satisfactory union without peritonitis after complex and anxious proceedings involving gross contamination of the peritoneum. If this fortunate outcome is rightly to be attributed to the drug, then several kinds of intestinal bacteria other than the mere coliform bacilli and cocci which grow in ordinary aerobic culture must be severely curbed by its influence. It is clearly desirable to know more about the capacity of sulphanilylguanidine for restraining the growth of different types of intestinal bacteria before random clinical trial in the vast range of intestinal diseases gathers its inevitable momentum. The evidence of such an effect so far is scanty, and the bowel contents of such an effect so far is scanty, and the bowel contents furnish so complex and apparently unfavourable a medium for chemotherapeutic action of this kind that success may well be partial and inconstant, or dependent on other factors which have yet to become known.

THE AQUEOUS AND GLAUCOMA

Only fifteen years ago standard textbooks in ophthalmology spoke of the aqueous as a filtrate or as a secretion formed by the ciliary epithelium and eliminated via Schlemm's canal. The cornea was thought to be impermeable and was expressly excluded as a drainage path. The intraocular pressure was considered to depend upon the secretory activity of the epithelial cells of the ciliary processes. The fact that the intraocular pressure is supported by the corneo-scleral envelope was ignored, and the impossible assumption was made that the sclera was a rigid inextensible structure. Glaucoma was believed to result from the back pressure occasioned by blocking of Schlemm's canal, or from the mechanical consequences of increase in size of the lens with age, or from swelling of the vitreous. To-day no one would support all these statements and assumptions, and it may be of interest to summarize the views that are the outcome of modern research, although it cannot be claimed that finality has been reached.

The aqueous is a dialysate of the blood plasma, modified to a slight and as yet undefined extent by the activity of the epithelium of the ciliary body and perhaps of the iris; in addition there are the products of metabolism of the lens, vitreous, and lining membranes. Throughout the eye interchange of substances takes place in both directions across the capillary walls, particularly in the ciliary body and iris. In articles on the nature of the aqueous Friedenwald,¹ and Duke-Elder, Quillian, and Davson² deplore the fact that recent writers have again started calling it a secretion. In using this term most ophthalmologists have taken it to imply that intraocular pressure is the result of secretory activity, although this meaning need not be attached to the simple statement that the aqueous is a secretion. Friedenwald denies that the composition of the aqueous shows that water is transferred across the ciliary membrane to produce an accumulation of fluid on the aqueous side. The secreted fluid so transferred can be taken only from the lymph of the ciliary body and processes, and this lymph is certainly at intraocular pressure. The transposition of fluid across the ciliary membrane could not cause a change in pressure, as there is no change in the total volume of the fluid. It is precisely this total volume of the contents of the globe which determines the distension of the corneo-scleral envelope, of which the intraocular pressure is an expression. It is thought that fluid is drained out of the eye in the region of the angle of the anterior chamber, that fluid may then pass into the cornea or into Schlemm's canal, and that obstruction of the angle is associated with some forms of glaucoma. The cornea is certainly permeable, and evidence that it is a normal drainage path is growing. The significance of Schlemm's canal as a drainage path is not thought to be great.

The intraocular pressure is derived from the capillary blood pressure, with which it is in constant equilibrium. It is less than this pressure by an amount which is attributable to the difference between the osmotic pressure of the aqueous and the blood plasma; it may be quite small or be as much as 20 mm. Hg. The pressure within the eye, as in any other container, is a function of the distensibility of the walls—in this case of the cornea and sclera, which behave very much as an artery does when distended. At normal pressures the corneo-scleral envelope exhibits perfect elasticity, expanding and contracting with every pulse wave and responding to lid closure and other external pressure, as would a rubber ball. When exposed to abnormally high pressure, however, the envelope stretches and subsequently is much less distensible, so that it acts as a contributory factor predisposing to a recurrence of such raised pressure. This fact, and the increase in the rigidity of the sclera with age, are important to any consideration of the problem of glaucoma. Changes in volume of the lens and vitreous have no bearing on the problems: the former theory has no supporters to-day, and it has been shown conclusively that the vitreous cannot swell under conditions compatible with life. Workers are now almost unanimous in regarding the blood pressure, particularly the capillary blood pressure, as the source of the intraocular pressure in health and disease. The internal pressure in all the blood vessels within the eye is necessarily in equilibrium with the support accorded by the vessel walls plus the intraocular pressure. This equilibrium is modified to only a slight extent by changes in systolic pressure, since in the eye (as throughout the body) the expanding force of the blood pressure is precisely balanced by the ever-varying tone of the muscular elements in the vessel walls. Glaucoma is thus attributed to the transmission of an abnormal proportion of the available blood pressure within the intraocular vessels to the extravascular contents of the globe. Since the volume of the extravascular fluid contents—the aqueous—is rapidly adjusted by passage either into or out of the capillaries, the intraocular pressure must be related to the capillary pressure over any prolonged period. This equilibrium will not be modified by drainage of aqueous out of the eye via the angle of the anterior chamber. The intraocular pressure may be further modified, however, by a change in the osmotic pressure difference between aqueous and blood plasma; but this change is probably small and cannot exceed 20 mm. Hg. Research is thus directed to a study of those factors, nervous and chemical, which may modify the tone of the capillaries and arterioles in the eye and their permeability. Much progress has been made, and much is now known about these agencies. There is evidence that vasodilator or vaso-toxic substances liberated by nerve action, formed locally as metabolites or entering the eye by the blood stream or via the cornea, may be the cause of clinical glaucoma.

THE NUTRITION SOCIETY

Elsewhere in this issue we publish particulars of the newly formed Nutrition Society. In giving it, as we do, a whole-hearted welcome, we are not to be taken as either assenting to or dissenting from any general proposition about the desirability of forming new scientific societies—even in peacetime. For such projects to be praiseworthy at least two conditions must be satisfied. First, the subject of the new society's activity must be of importance—as the patent lawyers might say, it must have "content"; secondly, there must be no other existing society that can cover the whole of the same ground equally well. On the second issue the new society can claim general support. The scientific attack on nutrition is, indeed, made from many directions—by medical practitioners, biochemists and physiologists, agriculturists and veterinarians, dietitians and sociologists, economists, statisticians, food technologists, and probably others. In the specialized organizations to which these various experts belong questions of nutrition will be discussed with less or greater frequency. Indeed, in medical organization the attention given to dietary factors is certainly still on the increase. But even here, and in the excellent meetings arranged through its Nutrition Panel by the Food Group of the Society of Chemical Industry, it is obvious that there is a lack of integration. At the medical gathering the biochemist and laboratory worker are likely to be in the background, the agronomist and the practical dietitian probably entirely absent; at the Food Group meetings medical views are unlikely to be represented, and veterinarians are probably as invisible as statisticians. If the new society can bring together all the contributors to our growing knowledge of the relationship between food and health it will certainly achieve something not yet achieved—primarily, perhaps, because it has never been attempted, at all events in this country. And it has so far not been attempted because the importance of the subject is still too little appreciated in many of the most influential circles. It is doubtful if the emphasis given to-day to problems of feeding the community would have been nearly as marked but for the exigencies of wartime. In this sense, but we are sure in no other, the Nutrition Society may possibly be considered a child of Hitler. There can be little doubt to-day—least of all in the minds of medical practitioners—that nutrition has become a subject with "content." For the investigations of nutritional problems, special and other new techniques have been increasingly needed; for the discussion of problems and techniques alike a new organization has been found necessary.

That there are many gaps—some of them enormous—in our knowledge of human and animal nutrition would not be denied by the most craft-conscious nutritional scientist. The meetings or conferences to be organized by the new society—if one may judge by the proposed Cambridge meeting on "The Evaluation of Nutritional Status"—are just of the type calculated to reveal these gaps and therefore to point to ways of closing them. In that sense, if in no other, the foundation of the Nutrition Society may legitimately be regarded as a contribution to the national war effort, for it cannot fail to give support to all those forces that, by stimulating

investigation and helping to disseminate its results, make for improvements in the dietary of the people as a whole and therefore in their health, their vigour, and their democratic independence.

MALARIA IN OFFICERS AND MEN FROM OVER-SEAS

It is important to remember that malaria is likely to occur among officers and soldiers who have returned to this country from service over-seas in a malarious country. The attacks may be relapses of a previous recognized infection, or they may be primary, especially in those in whom infection has been kept in abeyance by prophylactic treatment while in the endemic area. In the latter event a history of a previous attack may not be obtained, and the onset may be delayed for months after the cessation of prophylaxis. The need for early recognition and adequate treatment of cases of malaria is very great, and the possibility of this infection should be borne in mind in the presence of pyrexia without obvious cause, especially if associated with shivering, vomiting, and subsequent sweating, where there is a history of recent service in a malarious area. A high proportion of cases may be of the malignant tertian variety, in which severe symptoms may suddenly appear at the onset or later in the attack. If a patient shows clinical symptoms of malaria the lack of facilities for microscopical demonstration of the parasites in the blood should never cause delay in treatment, but before beginning anti-malarial remedies blood slides should be made for later confirmation of the diagnosis by microscopy. The War Office has issued a pamphlet, "Notes on the Treatment of Malaria occurring in Individuals returning from Service in Malarious Areas" (H.M. Stationery Office, 1d.), which will be of value to civilian medical practitioners as well as to Army medical officers. The lines of treatment concisely set out are grounded on Army experience, and they have been framed for the guidance of all who may be concerned. While the standard treatment detailed is that found to be best in the alleviation of symptoms and in prevention of relapse, and is the course recommended wherever possible, alternative lines of therapy are offered to meet circumstances in which certain drugs are not available. Precise instructions are given for the employment of anti-malarial drugs, Group A (quinine salts, and mepacrine hydrochloride) being anti-symptomatic and antipyretic and for treatment of the acute attack, Group B (pamaquin) being anti-infective and anti-relapse, for administration after the acute attack. Mepacrine is the British equivalent of atebirin and quinacrine; pamaquin is the British equivalent of plasmoquine; these two drugs must never be taken concurrently. There are brief directions for general treatment and for the handling of special symptoms. A section is devoted to intramuscular injection of quinine for heavy infections and severe symptoms. Another section prescribes the dosage and technique of intravenous injection of quinine for cases of great urgency, or for heavy infection with malignant tertian malaria, in which it may be the only means of saving life; it is fraught with danger and should never be used as a routine.

SCIENTISTS AND POST-WAR RELIEF

The British Association conference on "Science and the World Order," which was held in London during the last week of September, was a much larger affair than its promoters had looked for. The plan was to have a few papers to be discussed by British scientists among themselves, but men of science of other nationalities—some

of them exiles—proffered contributions, resulting in an amorphous conference, with sixty or seventy papers crowded into six sessions, with little or no time for general discussion or even effective presentation. The remarkable thing about the affair was its post-war spirit. So far as Albemarle Street was concerned during those three crowded days the war was already over, and all the hives were buzzing with reconstruction and relief after Armageddon. The problem was tackled from the point of view of the apparatus of government, of world planning, of technological advance, of biological teaching, and of social order and humanitarian aid. On this last subject Dr. Anni Noll struck a needed note when she begged the men of science not to forget, among much other reconstruction, the reconstruction of the family, already sadly disintegrated by evacuation and national service. One of the conditions of such reconstruction, she said, was the establishment of means of healthy living, from the point of view not only of medical attention but of housing, transport, food distribution, and facilities for education and leisure. She urged periodical overhauls of the family unit such as the Pioneer Health Centre at Peckham had sought to establish. A dark picture of nutritional deficiency in Europe, west as well as east, after the war was painted by a Continental medical man. Dr. Kodicek, who said that to prevent a major disaster plans for food distribution, the growing of food, and care of mothers, children, and sick would have to be organized with all speed. The help of separate Governments would be necessary, but they must work in collaboration under an international organization. Immediate help needed after the war would include medical supplies of all kinds, such as therapeutic sera and vitamin concentrates, also the training of doctors for service in distressed areas. An interesting statement was made to the conference by Mr. R. Allen of the American Red Cross, who has recently spent eighteen months in France, and has also been in Switzerland, Belgium, and part of Germany. In France since the German occupation the hospitals had been completely denuded of supplies and equipment, and the French had been left to set up hospitals in churches and schools, and to use surgical instruments purchased at hardware stores instead of through medical supply houses. The American Red Cross distributed hospital supplies alongside the German Army, from whom they had good co-operation. In non-occupied France children were being supplied with one pint of milk a day in the form of a specially reinforced powder, with added fat content and vitamins. He mentioned that the American Red Cross was now setting up in Geneva a reservoir of medicines and drugs for use in case of the development of any serious epidemics in Europe, of which there was a very real threat. It was trying to send medical and hospital supplies into Norway, Holland, Belgium, Yugoslavia, Greece, and occupied France. Among the less sombre notes struck in the conference was the plea of Mr. Philip Noel-Baker, M.P., for a sound food policy, with what Sir John Orr had called the minimum standard of maximum health as the starting-point in plans for post-war relief.

VITAMIN P AND CAPILLARY RESISTANCE

Manwaring and his co-workers¹ believed that "increased specific capillary permeability will be shown to be the dominant fundamental physiologic change in protein sensitization to which all other anaphylactic reactions are secondary." More recently Rapaport and Klein² have found forty-nine out of a hundred allergic children to have abnormal capillary fragility as determined by the Wright

modification of the Rumpel-Leede test, using Wright's standard of ten or fewer petechiae as normal, from ten to twenty as borderline, and twenty or more as evidence of excessive fragility. In a previous study of 110 normal children only twenty-six, or 23.6%, had been found to show excessive capillary fragility as induced by a positive pressure test. Twelve of the forty-nine allergic children were found in subsequent capillary tests to be consistently abnormal. Vitamin P was administered and the tests gave normal results in all twelve. Ten of the twelve required only 100 mg. of vitamin P (as calcium eriodictate) daily, but the other two required 150 mg. daily, to bring about the "cure." Brown and Wasson³ have measured the capillary resistance by the minimal amount of suction needed to produce one petechia or more when applied for one minute to the skin of the forearm just below the antecubital fossa. They found the average capillary resistance of 150 rheumatic children to be low, that it was subject to seasonal and climatic variations, and that the decrease in resistance which normally occurs with increasing age does not exist in rheumatic children. They also thought that severe reactions to injections of streptococcus filtrate might be related to low capillary resistance and to weather. They found a slight increase in capillary resistance in the treated over the untreated rheumatic children. They did not experiment with vitamin P therapy. Vacek,⁴ using citrin prepared by two commercial firms, confirmed its influence on capillary permeability, its shortening of blood-clotting time, and its lack of influence on the thrombocyte count and bleeding time.

RHEUMATIC FEVER AND STREPTOCOCCAL ANTIBODIES

After some sixty years of more or less intensive research there are now few infectious diseases of which the cause is entirely unknown. The great exception is rheumatic fever, where viruses, pleuropneumonia-like organisms, and bacteria have all from time to time been incriminated. In considering the aetiology of rheumatic fever, however, it is impossible to get far away from the haemolytic streptococci, although their exact relationship to acute rheumatism has never yet been accurately determined. The latest effort to arrive at some definite conclusion in regard to this relationship has been made by Mote and Duckett-Jones,⁵ who have intensively studied the antibody responses to haemolytic streptococci in patients with acute rheumatic fever.

The characteristics of the sera investigated were their antistreptolytic and antifibrinolytic powers and the amount of precipitins against the C species-specific Group A substance of Lancefield,⁶ the D, E, and K protein fractions of Heidelberger and Kendall,⁷ and the P nucleoprotein fraction of Lancefield.⁸ Before sera from rheumatic fever were studied investigations were made on sera from apparently normal persons. It was found that both the incidence and titre of streptococcal antibodies varied in the general population with age, general health, general economic environment, and the season of the year. Thus antibodies were highest in age groups 5 to 15 years, suggesting that numerous subclinical haemolytic streptococcal infections occur in this decade. As might have been expected, the occurrence of the several antibodies decreased as the economic level and the general standard of living

¹ *J. Amer. med. Ass.*, 1923, 80, 303.
² *J. Pediatr.*, 1941, 18, 321.

⁸ *Ibid.*, 1925, 42, 377.

increased, while the evidence showed that in the winter months there was a significant increase in streptococcal antibodies. It is thus not easy to arrive at any absolute value for the "normal" incidence of haemolytic streptococcal antibodies in a population. The normal level of antistreptolysin "O" in the control group, however, was concluded to be 150 combining units or less per c.cm. of serum, during the period of investigation. The antibody response was then studied in groups of patients with scarlet fever and with acute streptococcal pharyngitis; in both groups about 90% developed antibodies, frequently in high concentration, to one or more of the haemolytic streptococcal products tested. These antibodies could be detected in the blood for considerable periods of time. Analyses of similarly collected data from eighty-seven primary attacks of rheumatic fever revealed an equally high incidence of haemolytic streptococcal antibodies, whether or not there was a history of a preceding or an associated respiratory infection. Comparable data from 179 cases of recurrent rheumatic fever showed that in 73% antibodies to one or more of the streptococcal antigens appeared in the blood, often in high concentration, during the course of the illness. These antibodies persisted, sometimes for months after the onset of the infection, but finally returned to normal levels, even in the face of continuously active, sometimes even fatal, rheumatic infections. Mild or even severe recurrent rheumatic fever may, it seems, occur in rheumatic subjects without detectable clinical or serological evidence of a preceding or associated haemolytic streptococcal infection. On the other hand—and this is a subject which requires much further study—acute haemolytic infections may occur in known rheumatic subjects apart from recurrent rheumatic attacks. Both the rheumatic and the non-rheumatic subject, so far as antibody response is concerned, respond alike to infection with acute haemolytic streptococci.

The data brought forward by Mote and Duckett-Jones undoubtedly show that haemolytic streptococcal infection is often associated with acute rheumatic fever, but the essential mechanism responsible for producing rheumatic fever still remains unexplained.

BIOTIN, CO-ENZYME R, AND VITAMIN H

Biotin is an organic substance necessary for the growth of yeast. Co-enzyme R is necessary for the respiration of the root-nodule bacteria *Rhizobium* sp. Vitamin H is the substance which counteracts the ill effects of egg-white as a dietary constituent. It is almost certain that these three are one and the same substance. The unsuitability of dried egg-white as the sole source of protein in the diet of young rats has long been recognized and ascribed by various workers to the development of some toxic substance or to the destruction during the drying process of some hitherto unrecognized dietary essential.¹ In a series of papers during the last nine years H. T. Parsons and her colleagues^{2,11} have shown that the toxic substance of dried egg-white, whatever it may be, is present also in the fresh substance; hence it is not generated during the drying

process. They have also shown that the toxic effect can be neutralized by giving 20% of beef liver or various other foodstuffs. The curative substance in beef liver is partially destroyed by autoclaving at pH 8.0 for five hours, and it is entirely destroyed by ashing. Moreover, the ill effect of eating egg-white was not due to its antitryptic property. Kögl and his colleagues^{12,13} have made crystalline preparations of biotin from egg-yolk, and have found that it is contained in watery extracts of various organs and tissues of dogs, cows, a male calf, and a laying hen. The liver, spleen, kidney, and adrenals were the best sources of the factor. Williams and his colleagues^{14,15} have used the influence of biotin on the growth of yeast as the criterion for a quantitative determination of biotin. They used a thermocouple galvanometer for measuring the concentration of yeast cells in the medium at seeding and after growing with different additions of biotin. The medium found to be most suitable for the yeast contained sucrose, various salts, L-aspartic acid, inositol, β -alanine, thiamin (aneurin), and vitamin B₆. The method proved to be quantitative within a concentration range from 0.00002 to about 0.001 μ g. (microgramme) of biotin. The following values of the biotin content (μ g. per g.) of foods were determined: cane molasses 2.1 and 1.7, beet molasses 0.06 and 0.7, liquid whey 0.12, whey solids 2.5, fresh egg-white 0.05, fresh egg-yolk 0.37, autolysed egg-yolk 0.35, moist autolysed yeast 0.13, fresh potato 0.01, autolysed liver solids 3.89. Biotin is some fraction of "bios." Many of its chemical properties have been determined. It is destroyed by nitrous acid at a rate which indicates that it may be an α -amino acid. György and his colleagues¹⁶ have found that both biotin and vitamin H are inactivated by benzylation and acetylation and by the action of nitric acid. They have lately¹⁷ identified a sample of crystalline biotin methyl ester prepared by themselves from a liver concentrate with one prepared by Kögl from egg-yolk, and by various methods of comparison have found them to have equal potencies with regard to vitamin H, biotin, and co-enzyme R activities. They therefore decided that the three factors are the same substance. Williams and his co-workers¹⁸ have recently measured the biotin intake and excretion of chicks fed on egg-white injury diets and the biotin content of their tissues. They have concluded that biotin is useful to the chick and that egg-white is harmful in that it destroys the biotin normally present in the chick's food. Only when biotin is given in amounts more than sufficient to satisfy the egg-white will there be any available for the chick. More recently¹⁹ the Cleveland workers (György *et al.*) and the Texas workers (Williams *et al.*) have collaboratively shown that the "toxic" substance in egg-white has albumin-like properties, and they have named it "avidalbumin." They concluded that it combines with the biotin, not destroying it, and that the compound so formed is excreted with the faeces. It has not yet been shown that biotin, vitamin H, or co-enzyme R is necessary for the human being.

On October 1 Sir Alexander Macgregor of Glasgow took office as President of the Society of Medical Officers of Health for the session 1941-2. He succeeds Dr. F. T. H. Wood of Bootle, who was elected for a second term of office last year.

THE ORGANIZATION OF AN EAR, NOSE, AND THROAT DEPARTMENT IN THE EMERGENCY MEDICAL SERVICE

BY

V. E. NEGUS, M.S., F.R.C.S.

Of all patients treated in the Emergency Medical Service a considerable proportion suffer from complaints affecting the ear, nose, and throat. A recent census taken at Horton Emergency Hospital showed that there were 114 patients in the wards set aside for the special department out of a total population of 1,500, the proportion thus being roughly one-thirteenth. Among the patients were 14 suffering from acute and chronic otitis media, 18 recovering from cortical and radical mastoid operations, and 2 on whom labyrinthotomy had been performed; 12 were in hospital for operations to correct deviation of the nasal septum, 21 were suffering from various forms of sinusitis, and 2 from carcinoma of the maxillary sinus; and 23 had been admitted for tonsillectomy. A variety of complaints were included in the remainder of the 114. This hospital has large orthopaedic and thoracic units; in hospitals with a smaller concentration of selected cases the proportion in the ear, nose, and throat wards would in all probability be higher.

The patients are divided into four categories, the relative numbers varying from time to time. There are civilian sick and civilian air-raid casualties, and Service sick and Service casualties. Among the Service cases are included Navy, Army, and Air Force personnel of both sexes, together with members of Allied Forces.

Segregation of Patients and Allocation of Special Wards

The specialized nature of the work and the inability to carry it out satisfactorily with patients scattered throughout the hospital, were in the early days of the war reasons for urging the necessity for segregation in wards set aside for the purpose. This request was met generously and with all possible collaboration by the medical superintendent of Horton Emergency Hospital, with the approval of the group officer. Similar assistance has been given by the superintendents of other hospitals in the sector, where special departments have been developed.

At Horton there are now two civilian wards, male and female, and two wards for Service cases, reserved for the head and neck unit; in them are housed all cases of disease affecting the ear, nose, and throat, together with patients suffering from injuries of these regions and of other parts of the head, including the eye. Two hundred beds are available out of a total accommodation of 2,000. The proportion of sick to wounded naturally varies from time to time. There are, however, at all times a large number of Service cases suffering from disease of the regions under question; they are admitted from a wide area.

Distribution of Special Clinics

In addition to Horton, there are in the sector other centres for ear, nose, and throat cases—at King's College and Dulwich Hospitals in London, at Sutton Emergency Hospital, the Blind School Hospital, Leatherhead, Cuckfield Emergency Hospital, and Horsham Base Hospital. Out-patients are seen at all these centres, and those requiring admission are taken into the appropriate hospital. Although the greater proportion of in-patients are treated at Horton, there is yet a considerable number at the other hospitals. It has been desired to develop efficient departments at each, with provision for medical and operative treatment, both for purposes of decentralization and to provide facilities for the immediate treatment of urgent cases of disease or injury. Certain types of case are transferred from the other hospitals to the main centre at Horton.

Medical Staff

A staff of part-time surgeons and whole-time assistants with special knowledge of the ear, nose, and throat has been allotted by the group officer, on whose co-operation the efficient treat-

ment of cases depends. The senior surgeon is director of the unit at Horton and is in general charge of the work of the sector; he is also consultant to the department at Sutton and visits other subsidiary hospitals as occasion arises. There is a second surgeon in charge of two wards at Horton, acting also as consultant to the E.M.S. hospitals at Leatherhead and Horsham. A third surgeon, whose time is occupied mainly with administrative work, deals with certain cases at Horton and other hospitals, including Haywards Heath and Dulwich. Another consultant has charge of work at King's College Hospital and at Cuckfield. Whole-time registrars, each with considerable specialized experience, carry out much of the routine work under the direction of the consultants. Two are at Horton, one at Sutton, and one at Leatherhead. Of resident medical officers, two are attached exclusively to the department at Horton, while at the other hospitals work is carried out by residents, with additional duties. The variety and the amount of the material afford excellent opportunities for the higher education of resident medical officers and registrars.

Desirability of Special Treatment

It is thus seen that an organization is provided in the form of out-patient clinics and in-patient wards, with a staff adequate to deal with the large number of patients requiring attention. From the civilian economic view and also from the military aspect, this organization appears to be desirable. The effects of diseases and injuries of the regions under question are in the main temporarily disabling but amenable to treatment; the great majority of patients are returned to full efficiency if given appropriate care. The civilian is enabled to return to his work in full health and the soldier to his unit as a fit man, except in a very small proportion of cases. From the utilitarian point of view, both civilian and military, a patient with an infection or an injury involving, for example, a nasal air sinus is deserving of greater consideration than an air-raid or military casualty with fractured skull and laceration of the brain. The former should be cured, while the latter will in all probability be invalidated out of his Service or civilian occupation.

Nursing

The nursing has been maintained at a high level of efficiency in spite of shortage of staff and other difficulties; and surgical results have been up to pre-war standards. The segregation of ear, nose, and throat and other head cases, under the charge of sisters accustomed to the work, has been of great benefit in every respect. The design of most of the wards at Horton is excellent for the purposes required. The subdivision of wards into sections and the provision of numerous small side-rooms allow separation of seriously ill from convalescent patients, while potentially infectious cases are readily isolated. Large galleries also are available to patients able to get out of bed, for meals and recreation.

Injuries and Diseases

The term "head injury" is often used to indicate cranio-cerebral conditions. If, however, a record is kept of all injuries to the head and neck admitted in unselected convoys it will be found that a large proportion concern parts of the head other than the cranium. Thus, of 577 head and neck cases out of a total of 3,917 casualties admitted to Horton between September 2, 1939, and May 1, 1941, 283 had injuries of the face, eye, nose, ear, neck, jaws, pharynx, larynx, and trachea. Injuries of the eye were most numerous, there being 126 cases, the face coming next with 87, and after that the ear with 74 cases. There were 14 wounds of the neck and 15 of the nose and sinuses, and 12 fractures of the mandible. The pharynx and larynx were each involved in one instance only, and the trachea in 3 cases. Wounds of all these regions present considerable difficulties and require the attention of specialists conversant with the surgical technique; the team must include not only ear, nose, and throat surgeons, but also ophthalmic and dental surgeons. Many patients have, in addition, injuries of other parts of the body, which must be looked after by general or orthopaedic surgeons; this applied to 82 out of the 577 cases under review.

Cranio-cerebral injuries are themselves often complicated by wounds of other regions of the head and neck, or of other parts of the body. It has been found desirable, therefore, to accom-

moderate all cases of head and neck injury in the wards specially set aside, and subsequently to transfer elsewhere those requiring specialized treatment.

At the centres other than Horton the immediate care of the injuries referred to has been carried out by the special registrar, if available, or by other members of the staff, in consultation with the visiting ear, nose, and throat surgeon.

Instructions for the systematic treatment of ear and nose casualties have been circulated, with special reference to the prevention of inflammatory complications. Large mixed convoys invariably contain cases of injury or disease of these special regions, either alone or associated with other complaints. It is essential to have available an organization for their immediate and efficient care.

Of injuries to the ear, rupture of the tympanic membrane is the most common, and is of considerable importance. Precise notes were kept of 55 such cases at Horton; a considerable number occurred also at other hospitals in the sector. Antiseptic precautions, carried out early, combined with lack of interference with the deeper meatus, are the methods designed to prevent infection in the middle ear. Of the considerable number of such cases seen at Horton and other sector hospitals three have required subsequent cortical mastoid operation.

Attempts have been made to avoid secondary infection in surgical cases by the routine wearing of masks by all members of the staff when treating patients or carrying out dressings. Masks are worn during all attendances on such infectious cases as those with sore throats; nurses and others with colds wear masks whenever in contact with patients.

Diseases.—The emergency hospitals care not only for air-raided casualties and a proportion of the civilian sick, but also for large numbers of Service patients suffering from diseases of the ear, nose, and throat. A considerable number of Service out-patients have also been examined and treated at each of the five clinics. It is thus apparent that the organization set up for the treatment of casualties is turned to good use for the care of the sick of the Services, the great majority of whom are returned fit to their units.

Records of Work.—Tabulation of all cases admitted provides a ready means of reviewing the work done. Figures can rapidly be compiled to show the numbers admitted suffering from the various types of disease or from the results of injury. The indexing carried out by the registrars has proved of considerable value in compiling this and other reports.

Operations

At the beginning of the war the necessity for a specially equipped operating theatre, in charge of a sister with previous experience of this type of work, was impressed on the authorities concerned. Such a theatre was provided at Horton, and in it not only all the ear, nose, and throat work has been carried out, but also operations for various types of head injury. At the other sector hospitals the amount of specialized work has so far been insufficient to justify the setting aside of a separate theatre, even if such were available; the requirements of the work, differing from that of other branches of surgery, are, however, only to be fully satisfied in a specially designed theatre. The wisdom, at the beginning of the war, of admitting civilian cases of disease for operation in the emergency hospitals outside London was demonstrated by the development of an efficient organization during the months preceding the admission of casualties.

The large numbers of operations performed for disease have been of great benefit in perfecting arrangements for dealing with casualties. At Horton two operating tables can be used in times of stress, the theatre staff being sufficient to deal with many consecutive cases, both by day and by night. By co-operation with the hospital authorities various alterations have been carried out in fitting up the theatre, thereby raising it to the standard of efficiency required before the war.

The number of operations for injury, excluding cranio-cerebral and eye cases, performed between September 2, 1939, and May 1, 1941, is somewhat meagre. A certain number of patients had been operated on before admission, while many others, including those with traumatic rupture of the ear, luckily were saved from operation by careful treatment. A total of 66 patients required operation, including 15 on the ear, 13 on the nose and sinuses, and 5 on the neck.

Of diseases the variety is considerable, and is equal to pre-war standards. It says much for the efficiency of the theatre staff that operations such as labyrinthotomy, laryngectomy, and laryngofissure for malignant disease or stenosis have been carried out with satisfactory results. Of cortical mastoid operations, 12 were performed on civilian and 15 on Service cases, while 26 radical operations were required for civilian and 31 for Service patients. A total of 124 submucous resections of the nasal septum are included in the list, and 179 operations on the sinuses for inflammatory diseases and 15 for neoplasms. Tonsillectomy was necessary in 304 cases. Other operations brought the total performed on the ear, nose, and throat to 920 in the period September 2, 1939, to May 1, 1941.

Equipment

It has been made clear, in the preceding pages, that a large number of sick and injured patients require treatment in the hospitals of the sector and that ample accommodation and a trained staff are available for their care. Unfortunately the equipment which I consider necessary has not been provided. That supplied is insufficient in quantity for the many patients who must be examined, treated, and operated upon in this sector, and is in many instances of a different pattern from that to which my colleagues, my assistants, and I have been habituated. The return of civilians to their war work and of soldiers to their units should not be impeded by lack of equipment. We have had to improvise instruments and use privately owned ones to fill the gap. It is to be hoped that the importance of the ear, nose, and throat department in the Emergency Hospital Service will be recognized and that it will be equipped more satisfactorily in the near future.

TEMPORARY REGISTRATION OF OVERSEA DOCTORS

A new Defence Regulation and a new Order made under it by the Minister of Health and the Secretaries of State acting for Scotland and Northern Ireland extend the classes of doctors who may be registered by the General Medical Council for the period of the war. Under the Regulation formerly in force it was necessary for a doctor to be by law entitled to practise in a territory to which the Regulation was applied by Order, and this precluded a doctor from registration if he had passed the necessary examinations for a diploma but was debarred from practice by racial legislation or otherwise. The new Regulation applies to all territories without limitation, and puts persons who have passed the necessary examination in the same position as if they had obtained the diploma and become entitled to practise.

The combined effect of the new Defence Regulation and the Order is that a doctor who does not possess any United Kingdom qualification may now be registered temporarily if he satisfies the General Medical Council that he fulfils the following conditions: (1) that he is of good character; (2) that he holds a medical diploma (or has passed the examinations for a medical diploma) recognized as sufficient by the General Medical Council; and (3) that he has been selected for employment as a medical officer in an approved hospital, institution, or service, or as an assistant to a doctor on the permanent Register. Special provisions apply to persons selected for medical commissions in the British or Allied Armed Forces. The fact of registration does not affect the obligation of an alien to comply with the provisions of the Aliens Acts and Orders.

Further reference will be made to this new regulation in the *Supplement* next week.

W. N. Sarker and B. P. Tribedi (*Ind. med. Gaz.*, 1941, 76, 257), who record five illustrative cases and emphasize the difficulties of diagnosis between uterine carcinoma and tuberculosis, have collected 3,744 unselected gynaecological biopsy specimens and 430 unselected necropsies in females between 1920 and 1940 for evidence of tuberculous lesions in the genital tract. The biopsy material showed an incidence of genital tuberculosis in 0.69%, while the necropsies showed an incidence of 8.9% in unselected deaths in females, and in 1.1% where death occurred from tuberculosis.

FOUNDATION OF A NUTRITION SOCIETY

Workers engaged on research on nutrition in this country have been feeling the need for a scientific society devoted specifically to their subject. In the past no organization has existed to enable investigators in the many and varied branches of the science—clinical, physiological, agricultural, and sociological—to find a common meeting ground for discussion and the exchange of views. Representative workers in all these fields accordingly decided to form a Nutrition Society. The new venture owed its inception to the following circular letter signed by the heads of some of the better-known centres for research on nutrition in this country.

Just before the outbreak of war a suggestion was made by several people interested in research on nutrition that a Nutrition Society should be formed. Owing to the outbreak of war the idea was abandoned. The question has, however, again been raised, and there are a considerable number of research workers and others in favour of holding meetings to discuss nutritional problems. Such meetings would serve a useful purpose, especially in enabling workers studying different aspects of the same problem in agricultural and medical institutions to meet and help each other with information and constructive criticism.

If there is a sufficient number of workers who wish to hold meetings for discussion of nutritional problems, the best procedure would be to form a society on the lines of the Physiological and the Biochemical Societies, although there would be no question of publishing a journal in the meantime.

In view of the difficulty of travelling it might be convenient to form separate English and Scottish branches, which would meet independently but which might maintain contact during the war by exchanging short notes on the papers and discussions at meetings.

Sir Joseph Barcroft, F.R.S. (Chairman, Food Investigation Board).

Dr. Harriette Chick (Head of Division of Nutrition, Lister Institute).

Prof. J. C. Drummond (Scientific Adviser to Ministry of Food, and Professor of Biochemistry, University College, London).

Dr. John Hammond, F.R.S. (Superintendent of Animal Research Station, Cambridge).

Dr. Leslie J. Harris (Director of Nutritional Laboratory, Cambridge).

Sir Frederick Gowland Hopkins, O.M., F.R.S. (Professor of Biochemistry, Cambridge).

Prof. H. D. Kay (Director of National Institute for Research in Dairying).

Sir Charles J. Martin, F.R.S. (Roebuck House, Cambridge).

Sir Edward Mellanby, F.R.S. (Secretary, Medical Research Council).

Sir J. B. Orr, F.R.S. (Director, Rowett Research Institute).

Prof. R. A. Peters, F.R.S. (Professor of Biochemistry, Oxford).

Subsequently a meeting was held at the Royal Institution attended by representatives from the various institutes, and the following provisional committee was formed: Sir John Orr, chairman; Dr. John Hammond, vice-chairman; Dr. Leslie Harris, honorary secretary; Mr. A. L. Bacharach, honorary treasurer; Dr. Harriette Chick; Dr. E. M. Cruickshank, Cambridge; Dr. H. H. Green, Veterinary Laboratory, Weybridge; Prof. H. P. Himsforth, University College Hospital; Prof. A. St. G. Huggett, St. Mary's Hospital; Dr. Franklin Kidd, Food Investigation Board; Dr. S. K. Koon, National Institute for Research in Dairying; Dr. B. S. Platt, Medical Research Council; Dr. H. M. Sinclair, Department of Biochemistry, Oxford.

It is, of course, not intended that the new society should compete in any way with existing scientific societies: its functions would be complementary to theirs, and would cover a more general and in some ways less specialized field. The main activity of the society at the start would be to hold meetings at various research institutes, at each of which some specific topic could be discussed: several main papers would first be read and would be followed by a general discussion. Arrangements have been made to hold the first conference of this kind at Cambridge on October 18, when the theme will be "The Evaluation of Nutritional Status." Contributions have been promised by Sir Frederick Hopkins (introductory address), Dr. Leslie Harris (Assessment of Level of Nutrition in Man), Dr. B. S. Platt (Clinical Signs of Dietary Deficiency), Dr. C. Crowther (Nutrition of Farm Animals). Among those who have promised to take part in the discussion are Dr. H. M. Sinclair, Dr. John Yudkin, Dr. G. W. Robertson, Dr. R. H. Dobbs, Dr. W. C. W. Nixon, Dr. H. H. Green, Dr. John Hammond.

Further particulars of the society can be obtained from the Honorary Secretary, Dunn Nutritional Laboratory, Field Laboratories, Milton Road, Cambridge.

Local News

ENGLAND AND WALES

Bristol Hospitals Commission

The Nuffield Provincial Hospitals Trust, having accepted an invitation from the Bristol and District Divisional Hospitals Council to make a survey of municipal and voluntary hospitals and ancillary services in Bristol and district, has appointed the following survey committee, to be known as the Bristol Hospitals Commission: Sir Farquhar Buzzard, Bt., Regius Professor of Medicine in the University of Oxford, and chairman, Medical Advisory Council of the Trust; Alderman Sir George Martin, vice-chairman, Provincial Hospitals Regionalization Council of the Trust; Prof. G. E. Gask, F.R.C.S., president, Medical Society of London, member of the Medical Research Council; Dr. M. T. Morgan, medical officer of health, Port of London Authority; Dr. John Buchan, medical officer of health, City of Bradford; Dr. J. P. Candler, late medical officer, Ministry of Health; Dr. A. Q. Wells, medical secretary, Medical Advisory Council of the Trust; Alderman W. H. V. C. secretary, Nuffield Provincial Hospitals Trust; and Mr. S. Clayton Fryers, house governor and secretary, General Infirmary at Leeds. The terms of reference of the Commission are: "To take into consideration the present position of the voluntary and municipal hospitals and ancillary hospital and teaching services operating within the area of the Bristol and District Divisional Hospitals Council; inquire whether it is desirable that any steps be taken to promote further co-ordination or extension; consider how the existing and future services may best be financed and administered; and frame such recommendations as may be thought expedient and acceptable without prejudice to developments which subsequent inquiry may find to be desirable in other divisions in the projected West of England Region." The Commission has visited Bristol this week, with headquarters at the Council House. Preliminary work was undertaken by the Trust's officers. Each hospital has been invited to reply to a questionnaire, and the Lord Mayor has sent a letter to all contributory schemes in Bristol inviting them: (1) To submit observations on the present hospital accommodation and to make recommendations in regard to the future adequate maintenance and expansion of the hospitals and their progressive developments adequately to cater for the needs of the community. (2) To explain how, in their opinion, their organization can best help to solve the present financial problem of the Bristol voluntary hospitals, having regard to the principles on which the contributory scheme movement operates in the large cities, and how they can best help to implement the recommendations they have made under (1), assuming such recommendations to be acceptable to the hospitals.

dary schools have to the tradition and prestige of the oldest of our public schools. Similarly, the religious spirit and charity so emotionally described in Dr. Geoffrey Evans's letter are hard to reconcile with the economic conditions which we all know to-day compel medical and nursing and all other hospital staff to think, and to think hard and realistically, in terms of salaries and wages, and to press their demands with no uncertain meaning upon their employers, whether national, municipal, or voluntary. Likewise it is surely inaccurate to say that the voluntary system depends to an extent upon charity, when "charity" in the proper sense of that word in actual practice means that every hospital chairman and secretary is racking his brains for some new method of raising money to supply the essential needs for the proper care of their patients. Bridge parties, matinees, students' clownish processions, nurses in uniform with collecting boxes at street corners, disfiguring advertisements on the walls of hospitals setting forth the virtues of some proprietary food or drink, and so forth, do not seem to me to breathe the real spirit of charity.

Personal service, whether it be exemplified by the governors or the nursing and medical staff, without immediate reward, is not a virtue peculiar to the governing boards of voluntary hospitals, and is certainly untrue of both the nursing and medical staff, inasmuch as the nursing staff are paid like any other staff and the medical staff have in their capacity as members of the hospital staff their biggest asset in creating a remunerative private practice. The term "honorary" staff is to-day a misleading description, but useful as one of the items included in appeals for subscriptions, donations, and legacies. Independence and self-reliance, properly practised, are admirable virtues, but who is there to-day who is prepared to deny that the independence of voluntary hospitals, as hitherto understood, has been carried to such an extreme that it has almost precipitated their downfall? Indeed, is it not true to say that this very independence has almost succeeded in destroying democracy? Nor do I agree with the wholesale condemnation of the medical superintendents of municipal hospitals. If I were challenged to do so I could without the least difficulty recite the names of many medical superintendents who during the last forty years have done magnificent work in their hospitals and whose example of high devotion to duty is among the treasured memories of many scores of those younger members of our profession whose good fortune and privilege it was to work with them. The simple truth is, of course, that just as there are voluntary hospitals and voluntary hospitals, so there are medical superintendents and medical superintendents; and therefore generalized "boosting" of the voluntary hospitals as if every one of them possessed even those features which we all agree are "their best features" is just as silly as general condemnation of all medical superintendents and the attribution to them of those bad features which we all wish to remove from the municipal hospitals. In this connexion here are very brief extracts from a memorandum recently written by a distinguished member of our profession which should give Dr. Geoffrey Evans and his friends pause to think realistically and not emotionally.

"The weakness of the present system of staffing voluntary hospitals lies in the fact that the services rendered by the medical man to the hospital are not his primary concern. They are essentially secondary, a means to an end, the end being the development of an adequately remunerative private practice. . . . The voluntary hospital system at present suffers in so far as its service is subordinated, consciously or unconsciously, to the influence of private practice."

These words, and many more like them, severely condemning present conditions in our voluntary hospitals were recently written by an eminent voluntary hospital man and endorsed by a number of equally eminent members of the staffs of our voluntary hospitals throughout the country. What about tradition, the religious spirit, charity, personal service, etc., after all that? And here I would remind your readers that there are a large number of lay men and women in this country who devote themselves wholeheartedly, and often at great personal sacrifice, to the direction and management of the heavy duties and responsibilities of local government, including the public health and hospital services, and also that if Dr. Geoffrey Evans and his friends really wish to see the best example in this country of the "Florence Nightingale" nursing spirit they should go and spend a week or two in one of our large municipal hospitals for the care of the chronic sick.

Dr. Malcolm Donaldson is right when he says he hopes "to see very drastic reforms in the near future in the voluntary hospitals." So do I when I think of the grossly overcrowded out-patient departments, with patients waiting for hours to be seen and more often than not ultimately examined superficially by a junior and quite inexperienced member of the medical staff and sent away with a bottle of medicine or a lotion or bottle of lozenges, or again when I think of the pride with which one is told that there are some hundreds of patients on the waiting list for admission, many of whom will have no chance of a bed for weeks or even months, and so forth. It would be easy to extend the catalogue of the worst features of the voluntary hospitals, but that is not the question to which one wished for an answer, any more than one asked for abuse of the medical superintendent. It appears to me that the nearest approach so far to an intelligent reply to my questions is contained in the admirable letter of Mr. Lang Stevenson (September 27, p. 456). The third paragraph of his letter gives a brief but excellent exposition of the "best features of the voluntary hospital system," but I think it is probably true to say that they are only to be found in most of our teaching hospitals and in a very limited number of non-teaching hospitals. I do not suppose that Mr. Lang Stevenson means to suggest that his description is characteristic of the voluntary hospital system generally, but only of the best of the voluntary hospitals. Nevertheless, they are the features we want to preserve. I find myself wholly in agreement with the eight suggestions he makes for removing some of the defects of the municipal hospital system, and I am happy to think that practically all of them were actually introduced into the L.C.C. hospital service between 1930 and 1939, as well as quite a number of other county hospital services within my personal knowledge. It would scarcely be possible to point to a hospital, voluntary or municipal, in this country which more nearly approximates to the ideals of the best type of hospital than the British Postgraduate Hospital and Medical School at Hammersmith. Before war broke out that hospital was characterized by the unique combination of a medical staff devoted entirely to clinical work and research and an L.C.C. medical staff which took over the entire control of the administrative work of the hospital.

Finally, may I add that in this matter of the best features of the voluntary hospital system there is too great a tendency on the part of voluntary hospital supporters to think of voluntary hospitals in terms of the best of our teaching hospitals, and to assume that what is true of our teaching hospitals is equally true of all of our voluntary hospitals. Similarly there is still a tendency among voluntary hospital supporters to think of the municipal hospitals of to-day in terms of the old Poor Law infirmaries of pre-1930. This is a profound mistake. Much has happened in the matter of improvement in the municipal hospital service since the Local Government Act, 1929, came into operation on April 1, 1930, and much more still would have happened in the next ten years had it not been for the outbreak of war. For the moment progress is arrested, but in due course progress will be resumed. The municipal hospital service is only a few years old; it has gone through a very difficult period of transition in 1930-9; it was well beyond its "teething troubles" before 1939. The voluntary hospital system has been in operation for centuries and has been fortunate in every respect in the support which it has attracted from all classes of society and all ranks of the medical profession. Hence one's desire to obtain a clear picture of what is meant by its best features, how far it would be practicable to introduce them into the new municipal hospital service which we all know has come to stay and which may indeed in the near future become the only hospital service. From that point of view the correspondence published up to now in the *Journal* has been helpful, but not, I confess, quite so helpful as one had fondly hoped.—I am, etc.,

FREDERICK MENZIES.

Criccieth, Sept. 30.

Medical Education

SIR,—Those who have not had experience of teaching physiology will agree with your recent leader (September 6, p. 340) that clinical cases would be of benefit in teaching, say, the nervous system, but those who have tried this have been grievously disappointed in its results. Many years ago Halliburton, in conjunction with Mott, tried this and found it a failure, but finding

this difficult to understand I, too, have tried it, with similar results.

The difficulty is that the non-clinical student has not yet become accustomed to the sick man and takes such a great interest in his clothes and in the human side of the cases generally that he fails to pay attention to the reactions of the nervous system. There is no doubt that applied physiology should be taught, but it should be when the students have become accustomed to clinical examinations and preferably have had six months' medicine and surgery. Then, as has been my experience at St. George's Hospital, students become almost embarrassingly eager to learn the exact scientific explanation of signs and symptoms.—I am, etc.,

London, Sept. 27.

R. J. S. McDOWALL, M.D.

SIR.—I was greatly interested in your academic issue of September 6 and in the correspondence evoked by its contents so far. We are living in an age of change and transition, and in this may safely be included medical education. The articles by the teacher and the taught on the subject are very fraught with possibilities, and your leading article contains much good meat. Representing neither teacher nor taught, but working in the non-academic medical realm, I feel some things need to be said.

In teaching medicine and surgery, and their ancillary subjects, I feel it would be far better if those members of the staff who had a flair for teaching did the work. Clearly, in a hospital, some physicians and surgeons are obviously pure clinicians, whereas others are that and teachers as well. Lectures and ward rounds and out-patient sessions should be left to those who know how to teach and, as we say colloquially, "know how to put it across." In commerce good salesmen study window-dressing, so in medicine academic window-dressing is urgently needed. A man may be a specialist, for example, on cardiac disorders and yet may be a very poor exponent of his knowledge on that subject. The art of lecturing needs as skilful preparation as does, for example, the art of surgery. Lectures have fallen into disrepute, and deservedly so, because some lecturers do not present their material in an attractive and palatable form and usually have a very small background of classical training. The same principle holds good for writers of textbooks.

The curriculum, as constituted, is for the most part satisfactory, but needs to be more practical in some places. The main subjects of medicine, surgery, and pathology are well taught, but some of the special subjects need better arrangement—for example, diseases of the eye, ear, nose, and throat. Queuing up to see an optic disk or a tympanic membrane is unsatisfactory. Gynaecology could be better dovetailed in with surgery, and obstetrics left to stand by itself. In view of its vital importance more time should be devoted to obstetrics, a subject combining medicine, pathology, and surgery. Another vital subject is anaesthetics, which is important in all medical spheres: one month's clerking and some six lectures are not good enough. Public health problems deserve more stress than at present in maintaining the national health and in prophylaxis against infectious diseases and other grave scourges.

Psychological medicine is coming more and more into its own and deserves better treatment. My teacher, E. B. Strauss, teaches that "psychiatry is the other half of medicine itself." Organic disease is so often founded on the bedrock of mental stigmata, and few doctors leave hospitals with an adequate psychiatric background and recognize patients as human beings rather than cases. More attention should be given to dietetics and to applied pharmacology, the basis of all true rational therapeutics.—I am, etc.,

Carriers of Tuberculosis

SIR.—We were very interested in the article on carriers of tuberculosis by Dr. James Maxwell (May 3, p. 665). It is interesting to note that Pendrill Varrier-Jones, in a lecture delivered in 1919 to the Royal Institute of Public Health, entitled "The Future of the Tuberculosis Problem," stated:

"Is it a fact, for example, that just as there are carriers of the germ diphtheria so there are carriers of the tubercle bacillus, who go through life without any symptoms which might at any time draw attention, and yet are the means of handing on the disease to several, nay many, persons? I might illustrate the point by a con-

crete example. A Cambridge undergraduate, a fine athletic man, developed what was diagnosed as an attack of influenza. Its course was prolonged and there was cough and expectoration. The sputum was examined repeatedly with negative results. The patient recovered completely. Some months afterwards he suddenly coughed up a mass of sputum, and being of a curious turn of mind brought it to the pathological laboratory with a request that it should be examined. Under the microscope the specimen was almost a pure culture of tubercle bacilli, so numerous were the rod-shaped organisms. The patient was apparently in the best of health. It may be argued that such a case would be very difficult to discern, very difficult to isolate, and it may well be that, among the well-to-do, those who live under the best conditions, the disease is spread by such an individual as I have just discovered."

The late Sir Pendrill Varrier-Jones was always insistent on the fact that tuberculosis carriers were a source of great danger to the public health, and was, we think, the first individual to draw our attention to the presence of carriers of this disease.—We are, etc.,

Tuberculosis in Glasgow

SIR.—The paper by Dr. Stuart Laidlaw and Dr. Duncan Macfarlane on the recent increase in the incidence of and mortality from tuberculosis in Glasgow (September 27, p. 436) raises points of special interest at the present time. They attach chief importance to overwork, strain, and curtailed rest as factors responsible for the increase in the notifications and deaths which they record.

The conditions which predispose the human body to active invasion by tubercle bacilli are varied, and it is not always possible to attribute to any particular factor its true position of relative importance. Drs. Laidlaw and Duncan are no doubt correct in concluding that strain is one of the principal aetiological factors, more especially if we accept the definition of strain as a prolonged over-call on physical, mental, and nervous energy. One of the effects of war on the civil population which was observed during the years 1914-18 was loss in weight irrespective of whether the individual was doing heavy manual work or not. Such loss in weight is due to one of two causes, or to both—namely, diminished intake of fats and proteins and increased metabolism arising from physical, mental, or nervous strain, and when it affects members of the young adult age group it is usually associated with impaired nutrition and diminished resistance.

The relationship between strain and nutrition should receive special attention at the present time. Apart from specific protection, resistance to tuberculosis is governed by the standard of nutrition and the degree of local resistance. We are liable to view the state of nutrition as depending exclusively on the amount and character of the food taken, but the standard of nutrition may be seriously impaired by strain and overcrowding. Emerson (*Nutrition and Growth of Children*, 1922) has drawn attention to the importance of over-fatigue as a cause of malnutrition in children and, consequently, as a factor in the incidence of tuberculosis. In the report on tuberculosis in Wales (*Anti-tuberculosis Services in Wales and Monmouthshire*, Report of Ministry of Health Committee, 1939) reference is made to the possible influence of stress or strain in increasing the injurious results of dietary deficiency, or in causing them to appear in persons who previously had shown no evidence of such deficiency. In a recent publication (*Tuberculosis and National Health*, 1939) I have stated that "war, especially when prolonged, leads to increase in the incidence of tuberculosis. Resistance is impaired by strain, fatigue, trauma, and interference with the normal supply of food, while the risk of infection is increased by overcrowding and the mass movements of population."

One point of significance to which Drs. Laidlaw and Macfarlane draw attention in their paper is the influence of curtailed rest and ill-spent leisure in promoting strain. One hesitates to suggest any curtailment of reasonable amusement and recreation for young people doing exacting manual work, but it is obvious that late hours under conditions of overcrowding and with inadequate ventilation due to lighting restrictions cannot but induce added strain and lead to impaired nutrition. Rest and sleep are essential for the young

adult to counteract the effect of physical, mental, and nervous strain.

The Government has wisely taken action to make a fairly balanced diet available and to provide additional fat-forming foods for certain groups of the population. The greater the amount of strain to which any section of the population is exposed the greater the need for an adequate intake of balanced articles of food. The Government has recently taken further steps in this direction by increasing the quantity and improving the variety of food for those undertaking heavy manual work. It would appear desirable, however, that some guidance should be given, especially to those in the young adult female age group who are doing work involving much strain, as to the need for rest and sleep, and as to the character of the recreation which is least likely to be injurious to health.—I am, etc.,

Rehabilitation of Injured Air Crews

SIR,—I read with considerable interest Flight Lieutenant R. N. Houlding's article on the rehabilitation of injured air crews (September 27, p. 429), and while I congratulate him on the work that is being done, I do feel that he is missing quite a lot by not utilizing occupational therapy to a much greater extent. To quote from the article: "More improvement is made in the early stages of treatment by encouraging the patient to concentrate on overcoming his disability by working away at it all day long. In the later stages the patient's attention is diverted from his injured part by participation in competitive games."
